WORLD ARMAMENTS AND DI

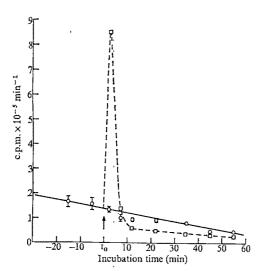

Fig. 2 Rate of extrusion of  $^{42}K^+$  from NN astrocyte cultures after  $6.25 \times 10^{-5}$  M ATP in the medium at  $t_0$ . Cultures labelled for 2 h with 5 mM  $^{42}K$ Cl, rinsed and superfused with Hanks' minimum essential medium. Average of duplicate experiments.

ATP concentration was 5 mM, <sup>32</sup>P extrusion into (and accumulation in) the superfusate proceeded at an accelerated steady rate. At lower concentrations initial efflux was even faster but soon decreased below the rates of the controls.

Testing of other compounds showed that a signal of the sort given by ATP could only be elicited with nucleotide triphosphates, and UTP, GTP and ITP were about equally effective. This was reminiscent of the ecto-ATPases with a similar lack of specificity towards nucleosidetriphosphates<sup>2</sup>. Tests with other ATP metabolites revealed that adenosine (but not uridine, guanosine or inosine) had an effect opposite to that of ATP. Adenosine decreased the extrusion rate of <sup>32</sup>P from labelled cultures and inhibited ATP-induced acceleration of <sup>32</sup>P extrusion at 10<sup>-6</sup> M; the effect seems to apply specifically to the transfer of <sup>32</sup>P.

A typical experiment with 42K+ pulse labelled NN astrocytes is illustrated in Fig. 2. After measuring the extrusion rate of  $^{42}$ K+ for 30 min,  $6.2 \times 10^{-5}$  M ATP was applied at  $t_0$ , resulting in an immediate fivefold increase in 42K+ efflux rate. Shortly thereafter apparent flux decreased below control levels, producing a biphasic signal in response to ATP application. A similar, apparently excitatory-inhibitory, response to ATP was observed by Harary and Farley in cultured beating rat heart cells7. At appropriate doses the effect of ATP on pulse labelled cells was observed in the N-18 neuroblastoma, HeLa cells, KB cells, glioblastoma GL-26 and L-929 fibroblasts. Different cell lines had significantly different dose responses to added ATP. The NN astrocytes responded to  $5 \times 10^{-7}$  M ATP, the N-18 neuroblastoma with not less than  $5 \times 10^{-4}$  M (Fig. 3) and sea urchin eggs, human erythrocytes and a human oligodendroglioma failed to respond.

The effect of ATP on ion permeation was temperature dependent. In the absence of Ca2+ no effect was obtained or it was markedly diminished. In the NN astrocytes 2 mM Ca<sup>2+</sup> was optimal and higher calcium concentrations inhibited the signal produced by ATP. Addition of 10% foetal calf serum to the superfusate did not inhibit the ATP effect. Attempts to demonstrate the ATP effect in cultures pulse labelled with 22Na+ or 36Cl- were not successful because these monolayer cultures are too clumsy a tool for studies which might involve time constants of the orders found in neurochemical transmission. Mostly using NN astrocyte cultures I have found that the ATP signal could not be elicited by acetylcholine, noradrenaline, caffeine, metrazol, inorganic pyrophosphate, phosphocreatin, 3', 5' cyclic AMP or strychnine. The following potential inhibitors proved inactive: ouabain, N-ethylmaleimide, colchicine, avidin, p-hydroxymercuribenzoate, ethylmorphine and theophylline. Oligomycin at 10 µg

ml<sup>-1</sup> inhibited ecto-ATPase activity by about 50%. The same concentration partially inhibited the ATP signal in some cultures, but it also effected a moderate increase in extrusion rates by itself. This again suggests an interrelationship between ecto-ATPase and the ATP-induced increase in permeation rates

Earlier observations may support the conclusion that these data reveal a physiological response. The apparent translocation of ATP from the cytoplasm into the environment has been observed under other circumstances. Aboud et al.8 found a considerable increase in 32P efflux from labelled frog spina root nerves and sartorius muscle during electrical excitation. They concluded that the outflux of acid-soluble phosphates, particularly <sup>32</sup>P<sub>1</sub> and AT<sup>32</sup>P, was somehow related to physicochemical changes of membrane depolarisation. In analogous experiments Silinsky and Hubbard9 detected ATP release from phrenic nerve-hemidiaphragm by the bioluminescence assay. Boyd and Forrester<sup>10</sup> observed release of ATP from frog skeletal muscle in vitro and it was also shown that ATP was released from exercising human forearm muscle11,12. An alternative explanation of the occurrence of extracellular ATP was advanced by Agren et al. 18,14 who observed apparent extracellular ATP synthesis by yeast cells and by various normal and neoplastic tissue cultures. The release of purine nucleotides-(by implication the translocation of ATP) is one of the principal elements of a purinergic autonomic nervous system which has been reviewed in detail by Burnstock<sup>15</sup>.

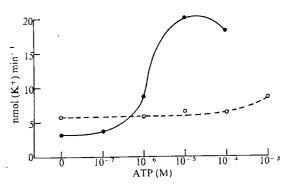

Fig. 3 Rates of extrusion of <sup>42</sup>K from pulse labelled NN astrocyte (●) and N-18 mouse neuroblastoma (○) cultures as a function of ATP concentrations at t<sub>0</sub>. Rates as efflux of <sup>42</sup>K min<sup>-1</sup> during the first 5 min after ATP addition.

The significance of my observations is that they offer an explanation for the presence of some enzymes on the surface o the cell. If ATP is translocated following a pertinent stimulus, i might impinge on the membranes of adjacent cells, effecting ar increase in permeability. In addition to the likely efflux of K the respondent cell might extrude some of its cytoplasmic ATI and thereby initiate the spreading or cascading transmission o a signal. Ecto-ATPase and ecto-5'-nucleotidase would then serve to limit or terminate the phase of increased permeability In the microenvironment a change in permeability or excit ability threshold might not be affected by the action of fre-ATP on the cell surface but by a membrane-bound species Conceivably, the entire process (presumably of altering th plasma membrane structure briefly) requires a phosphoryla tion reaction on the outer aspect of the membrane. One bio catalyst for this reaction might seem to be an ecto-ATPase.

# Relationship of α-adrenergic receptors in rat pineal gland to drug-induced stimulation of phospholipid metabolism

NORADRENALINE produces increased uptake of <sup>32</sup>P<sub>i</sub> into acidic phospholipids in the nervous system<sup>1-4</sup>, and neurotransmitters and other stimuli do so in various tissues<sup>5-7</sup>. The rat pineal gland responds to noradrenaline in similar fashion<sup>8-10</sup>. We have shown already that the mechanism by which noradrenaline stimulates phospholipid metabolism in the pineal gland does not depend on protein synthesis and does not involve either β-adrenergic receptors or cyclic AMP<sup>10</sup>. We also observed that the \u03b3-adrenergic receptor blocking agent propranolol not only failed to counteract the influence of noradrenaline, but itself markedly enhanced the incorporation of <sup>32</sup>P<sub>i</sub> into phospholipids to give a labelling pattern distinct from that produced by noradrenaline<sup>10,11</sup>. We concluded that this action of propranolol was due to its local anaesthetic or membrane perturbing property, since sotalol, a β-adrenergic receptor blocking agent without these other effects<sup>12</sup>, had no influence on phospholipid metabolism. In addition, a series of local anaesthetics yield effects comparable with those of propranolol<sup>13</sup>.

We now have clear evidence for two mechanisms for the stimulation of phospholipid metabolism by pharmacological agents in vitro. Using the rat pineal gland, we found that the effects of noradrenaline and the α-adrenergic agonist phenylephrine on pineal phospholipid metabolism are counteracted by a-adrenergic blocking agents, but that those of propranolol are unaffected.

Pineal glands were removed from ether-anaesthetised, female Charles River rats (150-200 g) and stored in ice-cold incubation medium until used. Individual glands were incubated free-floating in 100 µl of either modified Puck's N-16 medium (Grand Island Biological Co.) or Krebs-Ringer bicarbonate glucose medium containing 10 µCi of 32P<sub>i</sub> (New England Nuclear Corp.) and the desired amounts of drug. After incubation the glands were rinsed in saline and lipids were extracted with chloroform-methanol. Phospholipids were separated by two-dimensional thin-layer chromatography of the washed total lipid extract on Silica Gel H plates (Analtech). The areas which have been shown to correspond to the individual phospholipids under examination were scraped from the plates and counted10,11.

Addition of L-noradrenaline (0.01 mM) increased incorporation of 32Pi into phosphatidylinositol and phosphatidylglycerol by 200-300%, but had no effect on phosphatidylcholine labelling (Table 1). Similar stimulation was obtained with the α-adrenergic agonist phenylephrine (0.01 mM). Neither of the a-adrenergic blocking agents used, phenoxybenzamine (Dibenzyline; Smith, Kline and French) and phentolamine (Regitine; CIBA) at 0.02 mM increased labelling

Pineal glands were incubated in modified Puck's medium for 1 h in the presence of the agonists (0.01 mM), the blocking agents (0.02 mM) or both drugs together. Each value represents the mean  $\pm s$ . e. of the mean of at least four pineal glands. Differences from control means (no additions).

of phosphatidylinositol, although some stimulation phentolamine occurred with much larger concentrations of drug. Combinations of agonist and antagonist virtually abolished the response to agonist alone. Both a-receptor blocking drugs prevented the enhanced 32Pi incorporation into phosphatidylinositol and phosphatidylglycerol elicited by either noradrenaline or phenylephrine. These observations strongly indicate the presence of a-adrenergic receptors in rat pineal gland and their involvement in mediating the action of both phenylephrine and noradrenaline, the physiological pineal neurotransmitter, on pineal phospholipid metabolism.

Our finding that propranolol strongly stimulated 32Pi incorporation into lipids10 prompted us to attempt to discriminate between the modes of action of noradrenaline and propranolol. Such a distinction was suggested by different labelling patterns of phospholipids produced by these agents. The differences include stimulation of cytidine diphosphatediglyceride labelling and increased incorporation of isotope into phosphatidylglycerol and phosphatidic acid in the presence of propranolol compared with noradrenaline. We therefore investigated whether an a-adrenergic receptor blocker affected propranolol-induced stimulation of pineal phospholipid metabolism. Although it prevented the effects of noradrenaline or phenylephrine, phenoxybenzamine did not reduce the effects of propranolol (Table 2). The same resistance of propranolol-induced stimulation of pineal phospholipid metabolism to a-adrenergic receptor blockade was observed in experiments with Puck's medium and smaller concentrations of phenoxybenzamine or phentolamine (0.02 mM).

There are already indications that α-adrenergic blocking agents inhibit adrenaline-induced nonspecific stimulation of phospholipid metabolism, obtained with liver slices<sup>14</sup> and fat cell suspensions<sup>15</sup>. Robison et al. speculated that α-adrenergic receptors mediate the effects of catecholamines on phospholipid metabolism16. Later work has shown the ability of phenoxybenzamine or phentolamine to block enhanced phosphatidylinositol labelling from 32Pi, produced by adrenaline, noradrenaline or phenylephrine, in slices of parotid gland17,18 and vas deferens19 as well as in brain in vivo4.

The findings reported here are consistent with these observations. We have demonstrated that the rat pineal gland

possesses  $\alpha$ -adrenergic receptors which mediate the stimulatory effects of noradrenaline on pineal phospholipid metabolism. Earlier the suggestion was made that in the pineal gland "the response to  $\beta$ -adrenergic stimulation can be influenced by an a-adrenergic mechanism", since phentolamine enhanced the effect of noradrenaline on serotonin N-acetyl transferase activity<sup>20</sup>. Until now only β-adrenergic receptors have been definitely shown to be present in the pineal gland<sup>21</sup>.

It has been suggested that  $\alpha$  and  $\beta$ -adrenergic receptors act through a common mechanism, involving opposite effects on the intracellular level of cyclic AMP18. The authors of this hypothesis also cite instances, however, in which α-adrenergic receptor-mediated phenomena are not accompanied by a decrease in cyclic AMP. The pineal gland provides a further instance of stimulation of a-adrenergic receptors which does not depress cyclic AMP, since noradrenaline increases the level of this nucleotide21.

In rat parotid slices α-adrenergic receptors mediate the release of intracellular potassium by adrenaline, a process which requires Ca2+ and energy22 and which can similarly occur without changes in the cyclic AMP level of the cell. These observations suggest that the physiologically significant aspect of the stimulation of the acidic phospholipid metabolism brought about by catecholamines involves a relationship between the a-adrenergic receptor and ion movements. The pineal gland may be a suitable model system for the study of these interrelationships.

This work was supported by grants from the National Institute of Neurological Diseases and Stroke. We thank Mrs Alicja Skupny for technical assistance and Dr E. G. Lapetina for making his manuscript available before publication.

# Octopamine receptors on Aplysia neurones mediate hyperpolarisation by increasing membrane conductance

OCTOPAMINE is a phenylethylamine synthesised by β-hydroxylation of tyramine and differs from noradrenaline in lacking one hydroxyl group on the phenyl ring. Although Aplysia nervous tissue, like that of most molluscs, contains little or no noradrenaline<sup>1,2</sup>, it has between 0.20 and 1.85 pmol octopamine per mg of tissue in the various ganglia. Individual identified neurone also contain detectable octopamine and in neurone R14 i reaches  $1.5 \times 10^{-4}$  M (ref. 2). Although octopamine-activated adenyl cyclases have been found in Aplysia nervous tissue3 and insects4.5, there has been no electrophysiological demonstration of specific octopamine receptors. We now report receptors in the nervous system of Aplysia that are most sensitive to octo pamine and mediate a hyperpolarising conductance-increase response. This provides further evidence that octopamine car function as a neurotransmitter.

Abdominal, cerebral, pleural and pedal ganglia of Aplysia californica or Aplysia dactylomela were removed and pinned to Sylgard (Dow Corning) in a lucite chamber. The connective tissue capsule was slit with a razor blade to expose the cel bodies. Neurones were penetrated with a double barrelled glass micropipette filled with 2 M potassium acetate and recording was performed as before. Constant current pulses and/or current were applied through one barrel of the electrode as needed, while recording was made through the other. The

ganglia were constantly perfused with high Mg<sup>2+</sup> (150 mM) seawater, which blocks transmitter release from nerve terminals. Consequently, responses to iontophoretic drug application may be considered to be direct effects.

Octopamine and related compounds were dissolved in distilled water at concentrations of 1 M (pH 3-4) and each compound was placed in one barrel of a five barrelled iontophoretic electrode which was bumped at the tip to give a resistance of 2-5 M $\Omega$  for each barrel. The controller for the iontophoretic current was designed to pass a constant charge between 0 and 1,000 nC (J. Willis, in preparation). Thus the duration of the pulse was varied automatically to ensure that the same total charge was passed from each barrel, making possible a meaningful comparison of the response of one cell to several putative transmitters. When an octopamine response was found, the sensitivity of that site was tested with all other drugs in the iontophoretic electrode.

Responses to octopamine were recorded in cells from all ganglia studied but were obtained in only a small percentage of neurones. They were most common in cerebral ganglia, which also contain the most octopamine<sup>2</sup>. In all cases receptors for octopamine, like those for dopamine<sup>7</sup>, were not on the soma but rather in the neuropile. This may have led to an underestimation of the percentage of neurones containing octopamine receptors since it was necessary to search blindly for sensitive areas in the neuropile.

Figure 1 illustrates the response of a neurone in the cerebral ganglion to octopamine. A pulse of 1,000 nC octopamine resulted in a slow hyperpolarisation peaking at about 12 S. Pulses of 2,000 nC noradrenaline and phenylethanolamine, which differ from octopamine in having one additional and one less hydroxyl groups respectively, gave small responses. Dopamine was ineffective in exciting this receptor.

Figure 2 illustrates another experiment in which a pulse of 500 nC octopamine gave a 5 mV hyperpolarisation (a). When constant pulses (10<sup>-10</sup> A) were applied (b), the amplitude of the voltage deflection during the response was reduced. This reduction was not a result of nonlinear current-voltage relationships (not illustrated), and thus reflects an increased conductance to some ion, such as K<sup>+</sup> or Cl<sup>-</sup>, which has an equilibrium potential more negative than the resting potential. In (c) the ganglion was perfused with seawater in which all Cl<sup>-</sup> was replaced with acetate, which is relatively impermeable. In such a solution the equilibrium potential for Cl<sup>-</sup> shifts and becomes depolarising, as is the case for Cl<sup>-</sup> conductance responses to acetylcholine<sup>8</sup>. This response did not change, how-

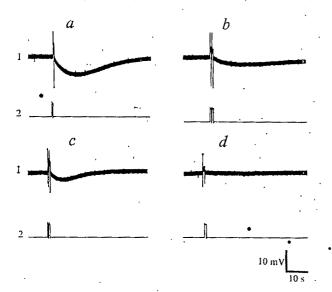

Fig. 1 Response of an unidentified neurone in the cerebral ganglion to octopamine (a), phenylethanolamine (b), noradrenaline (c) and dopamine (d). Trace 2 shows the duration of the iontophoretic pulse. Each pulse passed 1,000 nC. Double pulses were given for phenylethanolamine and noradrenaline.

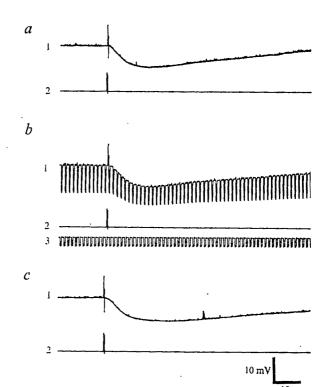

Fig. 2 Responses to 500 nC octopamine from an experiment on another unidentified neurone in the cerebral ganglion (a). For trace (b) constant current pulses (b-3) were applied during the application of octopamine. The smaller amplitude of the voltage deflection during the responses indicates a conductance increase since the neurone had a linear current-voltage relationship over this range of potential. For trace (c) the ganglion was perfused with Cl-free (acetate) seawater. Membrane potential was adjusted to control levels by applied depolarising current. The fact that the response is as large as control indicates that it is not a result of a Cl-conductance increase.

ever, and thus it is likely that it results from an increased K<sup>+</sup> conductance. It was not possible to reverse most of these responses by applied hyperpolarisation. This is probably because the receptors are all on distal processes in the neuropile. A similar difficulty has been reported in reversing K<sup>+</sup> conductance dopamine responses<sup>7</sup>.

The evidence for a neurotransmitter function for octopamine in Aplysia is threefold. (1) It is present in ganglia and is asymmetrically distributed in single, identified neurones. It is present in neurones that contain neither dopamine nor noradrenaline in concentrations as high as 10-4 M (ref. 2). (2) Octopamine receptors are located on a few neurones only and then only in the neuropile, where functional synapses occur. (3) The receptors have a marked specificity for octopamine. Most are also slightly sensitive to noradrenaline and phenylethanolamine, but to a much smaller degree. This suggests that the receptor has an absolute requirement for the β-hydroxyl group and as a result is insensitive to dopamine. Since there is no noradrenaline in Aplysia<sup>1,2</sup>, the responses to it have no functional significance. Phenylethanolamine is present in Aplysia nervous tissue (J. Saavedra, M. Brownstein, D. O. C. and J. Axelrod, unpublished observations) and receptors specifically sensitive to phenylethanolamine are present (our unpublished observations). The sensitivity of the receptors illustrated here is so much greater for octopamine that it seems likely that this is their physiological function. Neurones of the land snail respond to octopamine as well as dopamine and noradrenaline, but none have clearly specific receptors for octopamine only.

Octopamine is present in the nervous and innervated nonnervous tissues of mammals<sup>10</sup> as well as various invertebrates<sup>9,11</sup>. But, as octopamine can replace noradrenaline at its storage sites and be released on nerve stimulation<sup>12,13</sup>, it has been considered to be a false neurotransmitter. Molinoff and Axelrod<sup>14</sup> proposed that, since octopamine is a normal constituent of rat sympathetic nerves, it might normally be released together with noradrenaline. The combination of the demonstration of octopamine in neurones not containing other phenylethylamines and receptors very specific for octopamine argues strongly for a neurotransmitter function of octopamine in Aplysia which is independent of any other structurally related compound.

### Sustained oscillations of acetylcholine during nerve stimulation

THE neurotransmitter acetylcholine (ACh) is synthesised and stored in nerve terminals. Its turnover, rather slow under resting conditions, is greatly accelerated by nervous activity. When action potentials reach the terminals they trigger the release of large amounts of transmitter into the synaptic cleft where ACh can act on postsynaptic receptors and become a substrate for cholinesterase. Then choline and in some cases1 acetate moieties are taken up by the nerve endings and incorporated into new ACh which, in turn, can be rapidly reused. To investigate the turnover of ACh during activity, we have measured acetylcholine at short time intervals after the exposure of the nerve to electrical stimulation at different frequencies. We report here that the concentration of ACh oscillates following the onset of stimulation, and that the period of oscillation is related to the stimulation frequency. The experiments have been performed using the electric organ of Torpedo, a purely cholinergic tissue, which is very homogenous and rich in ACh2-4.

Torpedo marmorata fishes were received alive from the Station de Biologie Marine, Arcachon, France. Most experiments were done on isolated prisms, which are columns of electroplaques representing the functional unit of the organ3. After careful dissection, the prisms were allowed to recover for 1-2 h in an elasmobranch saline medium which maintains the functional and structural properties of the tissue<sup>5</sup>. The prisms were submitted to electric field stimulation for a given time and then rapidly quenched, by one of the following methods. (a) Tissue was plunged into liquid nitrogen, pulverised and allowed to thaw in trichloracetic acid (TCA) which was then extracted with ether, and the ACh determined using the frog rectus muscle bioassay. (b) Saline elasmobranch medium acidified to pH 4 with HCl at 100° C was used. The results obtained with these two methods were identical. The time lag between the end of stimulation and immersion in liquid nitrogen or boiling acidified medium did not exceed 1-2 s.

Figure 1a shows the typical changes in ACh content which occur when the tissue is stimulated. At rest (time of stimulation = 0) there was a rather large dispersion of ACh values, perhaps because the prisms were at different starting conditions. During the first 2s of stimulation, ACh content decreased. After this the first peak was seen, which in all experiments looked sharp and exceeded the mean resting content. The second peak was always lower; at this stage there was again a large dispersion of values. But 20 s from the onset of stimulation,

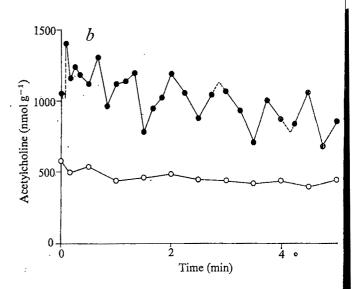

Fig. 1 Dynamic pattern of ACh changes during stimulation. ACh is expressed as nmol per g wet tissue. a, During stimulation at 20 Hz, the period of oscillation is too close to the frequency of sampling to permit a description of the form of the oscilla-tions (results from two experiments on the same *Torpedo*). b, Stimulation at 10 Hz. The bound or vesicular compartment of ACH (O) did not follow the large oscillations of total ACh (O), therefore the changes are largely in the "free" compartment.

the amount of ACh started to show oscillations with a regular period of about 10 s for a stimulation frequency of 20 Hz.

In Fig. 1b the tissue was given a stimulation of 10 s After the initial changes (the first fall, missed here, was found at 2s in another experiment) ACh content oscillated with a period of about 42 s. In this experiment, bound or vesicular ACh was also measured in prisms by immediately homogenising after stimulation and then treating with TCA. In this

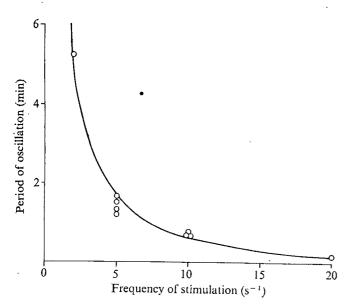

Fig. 2 Period of the ACh oscillations as a function of stimulation frequency. The line is an hyperbola calculated for the best approximation to experimental values.

case, the ACh remaining in the extract is regarded as ACh bound in a compartment associated with synaptic vesicles4,6 whereas ACh hydrolysed during homogenisation (about half of the total amount) is "free" or "available" ACh5,7. Fig. 1b shows that bound ACh did not oscillate during stimulation. Clearly the large variations in the total ACh concerned only the available pool of transmitter. If stimulation is continued, however, a decrease in the vesicular ACh also will occur<sup>5,7,8</sup>.

The variations in ACh content followed the same general pattern at other stimulation frequencies. The period of oscillation approximated a hyperbolic function of the stimulation frequency (Fig. 2). The delay of the first peak obeyed a slightly different relationship, reaching a limit at high stimulation frequencies. At the lower frequencies the shape of the oscillation was far from a sinusoidal wave; the peaks were separated by flat intervals and their rising slope looked smaller than their fall. In a few cases, the electric tissue was also stimulated in vivo through the nerves, the animal being slightly anaesthetised<sup>5</sup>. The results obtained under these conditions were the same as those from excised prisms.

Thus we found that, when driven from the resting to the active state, the electrogenic tissue exhibits a remarkable dynamic pattern. After a somewhat complicated initial phase, the ACh content follows undamped oscillations which are a function of the stimulation frequency. The dispersion of ACh values, rather high at the beginning, decreases during the oscillations. This behaviour could hardly be explained on the basis of a first order kinetic system, even if the conditions were far from equilibrium. On the other hand, sustained oscillations have been predicted and observed in more complicated systems coupled with a flow of matter or energy10-12. The oscillation arises at a key reaction, perhaps as a result of substrate inhibition or product activation of the reaction, although it can be caused in many other ways. For example, diffusion velocities to or through membranes can be important in such phenomena<sup>13,14</sup>. The result is that, when the rates of provision of substrate and removal of product fall between well defined limits, the system follows undamped oscillations, whose period is a function of the rate of provision of substrate. The flux through these systems is subject to sudden variations between two or more steady states, and the initial transition does not occur at the same substrate concentration as the reverse transition.

The resting turnover of ACh in this tissue (ref. 15 and unpublished observations) is about 104 times lower than the maximum speed of net synthesis measured in the present experiments. We think that the mechanisms underlying ACh oscillations are more than a curiosity. They are probably the result of highly regulated metabolic loops and might be a general property of pathways which, when passing from rest to activity, require accelerations of several orders of magnitude.

This study was supported by a grant of the FNRS. We thank L. Hirt and Dr K. Kaufmann for help and discussions.

### Evidence for a direct effect of LRF and TRF on single unit activity in the rostral hypothalamus

Many of the hormones produced by the pituitary and other endocrine glands influence the electrical activity of the brain (for recent references see Dyer1). There is now a growing awareness that some of the hypothalamic releasing factors, which regulate the secretion of hormones from the anterior pituitary gland, may themselves have a similar influence upon the central nervous system<sup>2-4</sup>. The amino acid sequences for both thyrotrophin releasing factor [TRF; (pyro) Glu-His-Pro (NH<sub>2</sub>)]<sup>5,6</sup> and luteinising hormone releasing factor [LRF; (pyro) Glu-His-Trp-Ser-Tyr-Gly-Leu-Arg-Pro-Gly (NH2)]7 have been fully established and these polypeptides, produced synthetically and of high specific activity, are readily available. The experiments to be described were undertaken to establish whether LRF and/or TRF have a direct effect upon the electrical activity of neurones in the forebrain. Action potentials were recorded from single cells in the hypothalamus and cerebral cortex and LRF and TRF applied to them by microiontophoresis. The sensitivity of some of the neurones to oxytocin (a biologically active peptide of similar size) was also tested.

Female rats were anaesthetised with urethane and prepared for extracellular recording of single unit activity8. Action potentials were recorded through glass micropipettes-filled

# tRNA's?

# Biogenics Research Corp. gives you the widest selection available.

Our name may be new to you, but we aren't new to transfer ribonucleic acid isolation and manufacturing. In fact, our experience (the longest in the field) and our techniques make it possible to offer you the broadest range of tRNA's available anywhere, plus a wide selection of amino acid specific tRNA's.

We will continue to add to the list: Our active research and development section deals exclusively with developing new isolation procedures as well as improving those already established. Uniquely, it also is responsible for stringent quality control of all of our production.

All tRNA's are supplied with analytical data sheets showing actual lot analysis including amino acid incorporation and a statement of chromatographic purity and degree of homogenicity. Specific amino acid acceptor tRNA's approach or equal theoretical purity (typically, 1100 pico moles per A  $_{260}$  unit of tRNA).

Please write for a free catalog detailing all of our products, including aminoacyl tRNA synthetases, enzymes, natural nucleic acids, oligodeoxy nucleotides and a variety of synthetic deoxy and ribo polymers.

with 4.0 M sodium chloride—with a tip resistance of 5-15M $\Omega$ , which constituted the centre barrel of multi-barrelled electrodes. These were made from glass electrode tubing (H15/10, Jencons) using established techniques and filled with 2.0 M sodium chloride, 0.01 M oxytocin (purified from natural material by Dr B. T. Pickering), 0.01 M LRF (Beckman Ltd and ICI Ltd) and 0.03 M TRF (Beckman Ltd). The overall tip diameter of the electrode was between 1.5 and 3.0 µm and the tip resistance for each pipette containing drugs was in excess of 25 M $\Omega$ . The drugs were retained within the electrodes by currents not exceeding 5 nA and ejected with currents of up to 300 nA, but usually in the range 5-30 nA. (We have not attempted to express the amount of releasing factor applied in terms of mol s<sup>-1</sup> since the conversion from nA requires many assumptions<sup>9</sup> and may produce a very misleading figure.) The polypeptides were only considered to affect the firing rate of a neurone when repeated applications caused at least a 20% change in the discharge rate of the cell over the test period. Routine applications were made for 40 s but some cells were tested for many minutes. Responses which could not be reproduced were excluded and where reproducible responses were obtained, their specificity was checked by application of oxytocin or Na+ at the same current. The apparatus and techniques used were similar to those previously described from this laboratory<sup>10,11</sup>.

Thirty-six single units were fully tested and of these 12 were recorded in the cerebral cortex and 24 in the preoptic and anterior hypothalamic areas (PO/AH). Oxytocin, LRF and TRF did not affect any of the twelve neurones tested in the cerebral cortex. Oxytocin was also without effect on any of the 8 cells tested in PO/AH (Fig. 1). LRF inhibited the spontaneous discharge of 4 out of 12 cells, however, (Fig. 2) and TRF had a similar effect on 7 out of 17 cells (Figs 1 and 2). One cell was excited by TRF and the remaining cells were not affected. Some of the unresponsive cells were subsequently tested by iontophoresing the releasing factors for many minutes but none of the cells exhibited any change in their firing rate which could be attributed to the drug application (Fig. 3). Although not all neurones were fully tested with both LRF and TRF, several units responded to one releasing factor and not the other (Fig. 1). Two cells were inhibited by both LRF and TRF (Fig. 2).

These results show that the releasing factors for thyroid stimulating hormone and luteinising hormone have the

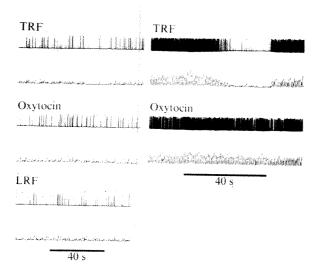

Fig. 1 The polygraph records on the left were obtained from a preoptic neurone which was inhibited by TRF (5 nA) but not LRF or oxytocin (8 nA). The two traces on the right show another unit inhibited by TRF and unaffected by oxytocin (both 7 nA). This second cell was not adequately tested with LRF. (Note, in this and the subsequent figures each action potential is represented by one excursion of the pen (top trace for each test) and an integrated record of this activity is shown in the lower trace. The test period is depicted by the black bar.)

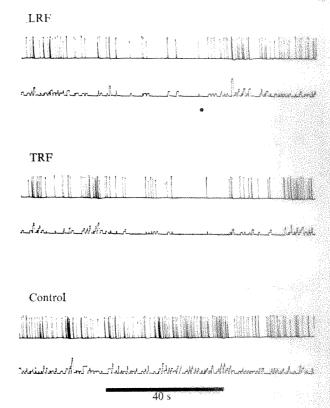

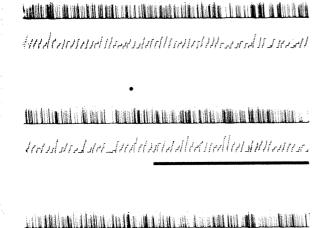

Fig. 2 Polygraph record showing inhibition of a single neurone in PO/AH by both LRF and TRF. The control was Na\* ejected at the same current (8 nA) as the releasing factors.

potential to modify the electrical activity of certain hypothalamic neurones. It is particularly interesting that these releasing factors did not affect all cells and did not influence the firing of any of the neurones tested in the cerebral cortex. It is also important that the firing rate of the responsive cells was neither increased nor diminished by microiontophoretic application of oxytocin at the same current, and that some cells responded to one releasing factor and not the other. Oxytocin has already been shown to excite antidromically identified neurosecretory cells in the paraventricular nucleus of rats and rabbits when applied extracellularly by microiontophoresis<sup>11</sup>. The experiments also showed that the hormone did not affect nonneurosecretory cells in the paraventricular nucleus and we have now extended these findings to show that neurones in the rostral hypothalamus are unresponsive to oxytocin.

The units inhibited by application of releasing factor frequently responded when rather low ejection currents were used (for example about 10 nA) and one cell even showed a substantial reduction in firing rate when the retaining current on the TRF pipette was turned off. On the other hand, many of the unresponsive cells were tested, with the same electrode as responsive cells, at much higher currents and for longer periods of time. Our results show therefore that a discrete population of neurones in the rostral hypothalamus is inhibited by application

of hypothalamic releasing factors.

If releasing factors are important in the control of hypothalamic function two possible routes of access to the neurones can be postulated. In the first place, the releasing factor may be secreted into the portal vessels from which they could be carried through the systemic circulation back to the hypothalamus. This is the conventional understanding of the so-called 'ultra-short loop' feedback system. An alternative mode of application could be trans-synaptic. That is, the releasing factors may be neurotransmitters secreted from branches of peptidergic neurones which do not terminate near the vessels of the primary plexus of the adenohypophysial portal system. In fact, there is some evidence that fibres stained by immunofluorescence for LRF do not always pass to the

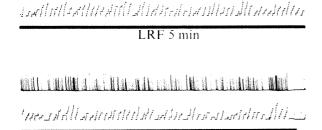

Fig. 3 Continuous polygraph record to show prolonged application of LRF (13 nA) on to a neurone which did not respond to the standard test period of 40 s. Note that even after 5 min the firing rate was unchanged.

median eminence. Such fibres have been described passing from the hypothalamus towards the mesencephalon and mammillary bodies as well as in the amygdala12.

A neurotransmitter function for releasing factors, in addition to their classical role, could provide a possible mechanism for the coordination of different aspects of hypothalamic function. There is no theoretical reason why neurones which secrete releasing factors into the hypophysial portal vessels may not have collateral branches which synapse on to other hypothalamic cells. In this way a single neurone or group of neurones in the hypothalamus could influence both the behaviour of the animal and secretion of its pituitary hormones.

We thank Mrs M. Plaster for technical assistance, Dr B. T. Pickering for purified oxytocin, Dr H. Gregory (ICI Ltd) for a gift of LRF, and the Population Council for financial support.

### In vitro enhancement of hepatic microsomal biphenyl 2-hydroxylation by carcinogens

Many natural and synthetic chemicals in the environment may be carcinogenic, but it is clearly impracticable to assess the potential hazard from all such compounds by existing in vivo methods. Simple preliminary screening procedures are therefore urgently needed to identify the compounds most likely to be hazardous and allow detailed study of these suspected carcinogens. A series of fundamentally different test systems involving a range of biological materials will probably be necessary. As most carcinogens seem to act through active metabolites produced by the enzymes of mammalian endoplasmic reticulum<sup>1</sup>, any test system probably requires the presence of these enzymes and the cofactor NADPH<sub>2</sub>.

Assessing the damage to the DNA of growing bacteria which is produced by carcinogens in the presence of mammalian drug metabolising enzymes—whether in vivo2 (host mediated assay) or in vitro using liver cell fractions (Ames test)3—seems to be the most successful approach so far. The estimation of changes inflicted on the endoplasmic reticulum, however, (such as the in vitro displacement of ribosomes (degranulation) of the liver endoplasmic reticulum by carcinogens in the presence of NADPH<sub>2</sub> (ref. 4)) and the in vivo effects of carcinogens on drug metabolising enzymes<sup>5</sup> are promising alternatives.

Here we report that the in vitro incubation of some chemically dissimilar compounds which are carcinogenic to rat hepatic microsomes in the presence of NADPH, produces a selective increase in biphenyl 2-hydroxylation, but has no significant effect on biphenyl 4-hydroxylation. Non-carcinogens do not enhance either hydroxylase.

The incubation system was as follows: Test compounds (carcinogens and non-carcinogens) in either groundnut oil, or in 1.15% KCl plus 1% Tween 80, were added to hepatic microsomes in buffer solution prepared from male adult Wistar rats (final protein concentration of 2 mg ml-1 in the presence of an NADPH-regenerating system of glucose-6-phosphate (25 mM), NADP (500 nmol), glucose-6-phosphate dehydrogenase (2 unit ml-1) and magnesium sulphate (50 mM) and the system preincubated for 10 min at 37° C in a shaking water bath at 100 cycles min<sup>-1</sup>. Biphenyl (13 mM in 1.15% KCl containing 1.5% Tween 80) was then added and the incubation continued for a further 5 min. The reaction was stopped by the addition of 1 ml of M HCl and the 2- and 4-hydroxybiphenyls thus formed were extracted and determined fluorimetrically6. In the controls, the test substance or biphenyl was either left out or added after the end of the reaction.

Preincubation of rat microsomes with a wide range of carcinogens such as 3, 4-benz(a)pyrene, aflatoxin B1, 2-acetamidofluorene and dimethylnitrosamine caused a significant enhancement of biphenyl 2-hydroxylation. In contrast, noncarcinogenic compounds, such as salicylate, phenobarbitone and 1,2,3,4-dibenz(a)pyrene, produced no significant effect on the biphenyl 2-hydroxylase. Neither class of compound produced any significant changes in biphenyl 4-hydroxylation (Table 1). Interestingly, carbon tetrachloride, a hepatotoxic agent and a questionable carcinogen, produced only a slight enhancement of biphenyl 2-hydroxylation. It is apparent that the enhancement of the hepatic biphenyl 2-hydroxylase activity is not confined solely to hepatocarcinogens for β-naphthylamine, benz(a)pyrene and methylcholanthrene are all effective.

This is probably because our in vitro system has optimal conditions for the metabolism of most carcinogens, which produce their active metabolites through microsomal metabolism, a situation which clearly does not pertain in vivo. The effect on biphenyl 2-hydroxylase seems to be relatively specific because other drug metabolising enzymes, such as p-nitroanisole demethylase and aniline hydroxylase, were either unaffected or slightly inhibited following preincubation with carcinogens and non-carcinogens (F.McP., J.W.B., and D.V.P., unpublished). Similar results have been found using hamster liver microsomes. The possibility of the carcinogen provoking an allosteric conversion between the two hydroxylases seems unlikely in view of the apparent lack of correlation between changes invoked in biphenyl 2- and 4-hydroxylation.

Table 1 The effects of preincubation with carcinogenic compounds on the biphenyl 2-hydroxylase and biphenyl 4-hydroxylase of rat hepatic microsomes

Results ± s.e.m. for six animals

Our observations may be the result of a direct effect of the carcinogen itself or may be mediated by the formation of an active metabolite. It is generally accepted that most carcinogens produce their in vivo effects through their metabolism to an active electrophilic or free radical intermediate7-10, probably effected by the NADPH-cytochrome P-450-dependent microsomal hydroxylase system<sup>1</sup>. Inhibitors of cytochrome P-450 could not be used directly to establish whether formation of an active metabolite from the carcinogen was a prerequisite for the enhancement of biphenyl 2-hydroxylase because they would also interfere with biphenyl metabolism.

Evidence that these carcinogens require metabolism before producing their effects, however, was obtained by examining the cofactor requirements and the incubation time dependency of the increased biphenyl 2-hydroxylase activity. A characteristic of the biphenyl 2-hydroxylase is that, unlike most drug oxidation reactions (including biphenyl 4-hydroxylation) it is not totally dependent on NADPH being able to utilise NADH instead. Thus, on preincubation of hepatic microsomes with safrole in the presence of NADH instead of a NADPHregenerating system, no enhancement of biphenyl 2-hydroxylation was observed although control values of this enzyme activity were unaffected by the change of cofactor. Presumably the explanation of this finding is that in the presence of NADH, safrole was not converted to an active metabolite. The length of preincubation time was also found to determine the degree of enhancement of the biphenyl 2-hydroxylase activity, optimal stimulation for safrole occurring after 30 min.

The quantitative significance of the figures quoted in Table 1 must be interpreted with caution for it is clear that the degree of enhancement observed is dependent not only on the rate of biological activation of the carcinogen but also on the concentration of carcinogen added. Thus, for 1 mM benz(a)pyrene maximal enhancement is observed within 5 min whereas for acetamidofluorene maximal enhancement is not achieved

Superficially, some correlation exists between the enhancement of biphenyl 2-hydroxylase activity and the degranulation of the endoplasmic reticulum but there are marked differences in other features of these two systems. For example, the carcinogen invoked biphenyl 2-hydroxylase enhancement is more rapidly mediated than degranulation; is considerably more susceptible to storage damage; and is not affected by EDTA (Table 1) which efficiently degranulates the rough endoplasmic reticulum11. The rapidity and relative lability of the carcinogen-stimulated increase of biphenyl 2-hydroxylase activity suggests that the carcinogens are modifying the membranes of the endoplasmic reticulum, perhaps invoking a conformational change which might subsequently lead to membrane damage

These results indicate that the study of the in vitro enhancement of biphenyl 2-hydroxylase in hepatic microsomes in the presence of a NADPH-regenerating system may prove a basis for a preliminary screening system which, in conjunction with other such tests, might be of considerable value in detecting potential carcinogens.

### Correlation of erythrocyte catechol-O-methyltransferase activity between siblings

CATECHOL-O-METHYLTRANSFERASE (COMT) is the enzyme that catalyses the conversion of noradrenaline, adrenaline, dopamine, and other catechol compounds to their O-methylated metabolites<sup>1</sup>. COMT is• widely distributed in many tissues including the red blood cell (RBC)<sup>1,2</sup> and individual differences in the activity of this enzyme in human beings may be involved in the pathogenesis of various psychiatric and neurological diseases<sup>3,4</sup>. Inhibitors of COMT have been used experimentally in the treatment of Parkinson's disease and other neurological diseases<sup>5</sup>. COMT activity is decreased in red blood cells obtained from depressed women<sup>3</sup> and is increased in erythrocytes obtained from children with Down's syndrome<sup>6</sup>.

Although there has been interest in the determination of erythrocyte COMT activity in blood from patients suffering from neurological and psychiatric disease, little is known about factors that regulate RBC COMT activity in unselected human populations. Here we describe a study of erythrocyte COMT activity in blood obtained from a large, unselected population of young men and women, the results of which demonstrate a significant correlation of COMT activity between siblings and suggest that there may be at least two human populations with regard to levels of activity of this catecholamine degradative enzyme activity in the erythrocytes.

Blood samples were obtained from 373 unselected adolescents aged 16-18 yr as part of a survey of lipoprotein values in students attending the Rochester, Minnesota schools. All but one of the individuals studied were white. Blood was obtained at school in the morning after an overnight fast.

Blood samples were withdrawn by venipuncture into plastic syringes and were transferred immediately to 2 ml heparinised vacuum tubes. COMT activity was determined in every sample on the day that the blood was obtained by use of a radiochemical enzymatic assay that is a modification of the method described by McCaman<sup>7</sup> (Fig. 1). 3,4-Dihydroxybenzoic acid was used as a substrate for COMT. One unit of enzyme activity represented the formation of 1 nmol of 4-hydroxy-3-methoxybenzoic acid (vanillic acid) per ml of packed red cells per hour of incubation. All results were evaluated by standard statistical methods.

Figure 1 shows the frequency distribution of erythrocyte COMT values in blood obtained from 373 unselected young men and women aged 16-18 yr. The mean COMT activity for the entire population was  $11.3\pm4.2$  (mean  $\pm$  s.d.); that of females was  $10.9\pm3.9$ ; and the mean RBC COMT activity of the male subjects was 11.8 ± 4.5. The distribution of COMT activity in this population seems to include at least two subgroups, one with a mean COMT activity of approximately 6-7 units and another with a higher mean enzyme activity of 12-14 units. This bimodality is present in the distribution of enzyme activities of the population as a whole and among the COMT activities determined in blood from the 189 female subjects and the 184 male subjects included in the study (Fig. 1). The same bimodality in the distribution of erythrocyte COMT values was found in a separate study of RBC COMT activity in 257 adolescents, 115 girls and 142 boys, age 13-15 yr in which COMT activity was determined in somewhat different assay conditions. In this younger population, as in the age 16-18 yr group, bimodality was present in the distribution of COMT activity of the entire population as well as in the separate distributions determined for male and female subjects.

A highly significant correlation (r=0.485) was found between erythrocyte COMT activity present in blood obtained from the 56 sibling-sibling pairs present in the population of young men and women aged 16-18 yr (P<0.001). The scatter diagram in Fig. 2 illustrates the sibling-sibling correlation of erythrocyte COMT values in this population. There was no difference in the degree of correlation between brother-brother, brother-sister and sister-sister pairings. When random pairs of single children with no siblings were generated by using tables of

random numbers, no significant correlation of erythrocyte COMT activity was found between members of non-sibling pairs. A highly significant correlation (r=0.59, P<0.001) was also present in blood obtained from the 37 sibling-sibling pairs included among the 257 adolescents aged 13-15 yr who were studied.

One of the difficulties in the determination of COMT activity in erythrocytes is the possibility that the results obtained might be due partially to the presence of endogenous inhibitors or activators of the enzyme. Both erythrocytes and plasma

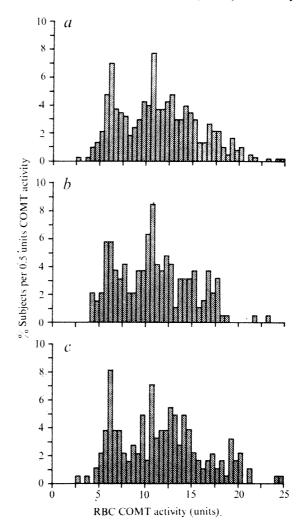

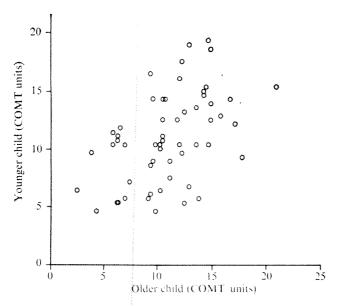

Fig. 1 Percentage frequency distribution of RBC COMT activity. The percentage of subjects with RBC COMT activity in successive 0.5 unit increments is shown for unselected populations that include: a, 373 males and females age 16-18 yr; b, 189 females and, c, 184 males considered separately. COMT activity was determined by a modification of the method of McCaman7. 200 µl of heparinised whole blood were added to 800 µl of ice-cold glass-distilled water containing 100 µl of a suspension of sodium Chelex-100. The lysed blood samples were mixed with the resin by rotation at 12 r.p.m. for 1 h at 4° C. After centrifugation at 700g for 10 min the supernatant was removed for the determination of COMT activity. 200 µl of the supernatant were placed in 15 ml stoppered conical centrifuge tubes to which 100 µl of a mixture of the following reagents final concentrations indicated) were added: Tris-HCl buffer, pH 7.5, 0.08 M; MgCl<sub>2</sub>, 10<sup>-3</sup> M; dithiothreitol, 4.2×10<sup>-3</sup> M; <sup>14</sup>C-methyl-S-adenosyl-1-methionine (specific activity 58 μCi μmol<sup>-1</sup>), 2.8×10<sup>-6</sup> M; non-radioactive S-adenosyl-1-methionine HCl, 20.2×10<sup>-6</sup> M; 3,4-dihydroxybenzoic acid, 10<sup>-3</sup> M. The reaction mixture was incubated for 45 min at 37° C, and the reaction was storyed with 100 u. of 1. N. HCl. The product was reaction was stopped with 100 µl of 1 N HCl. The product was extracted into 5 ml of toluene. After centrifugation, 3.5 ml of the organic phase were removed and added to liquid scintillation counting vials that contained 10 ml of toluene fluor. The radioactivity of the samples was determined by liquid scintillation counting. Blank samples included all reagents except 3,4-dihydroxybenzoic acid. Haematocrits were determined on all blood samples, and results were expressed as nmol of vanillic acid formed per ml of packed red blood cells per hour. (Details of the method will be published elsewhere 15.)

Sibling-sibling correlation of RBC COMT activity. RBC COMT activity determined in blood from the younger sibling in a pair is plotted against the activity of RBC COMT in blood of the older sibling. r=0.4846; P<0.001.

contain magnesium, an ion that is essential for COMT activity<sup>1</sup>. Variations in the concentrations of proteins that bind either endogenous or exogenously added magnesium might also influence enzyme activity. Blood contains S-adenosyl-1methionine<sup>4</sup>, a cosubstrate for the COMT reaction<sup>1</sup>. As the enzyme activity in this study was determined by the use of radioactively labelled methyl-14C-S-adenosyl-1-methionine, variable quantities of endogenous S-adenosyl-1-methionine in the blood might influence the apparent activity of the enzyme measured in a given individual. Finally, an enzymatic activity in blood that is capable of demethylating the product of the COMT reaction has been described<sup>8</sup>. Individual variations in this enzyme activity might also introduce artefacts into the determination of RBC COMT activity.

To help ensure that the individual differences in erythrocyte COMT activity reported here represent differences in the activity of the enzyme and not variations in the concentration of divalent ions, endogenous S-adenosyl-1-methionine, or other unknown inhibitors or activators of the enzyme, partially purified rat liver COMT was added to 201 consecutive blood samples in which RBC COMT activity was determined. Rat liver enzyme was purified by a modification of the method of Axelrod and Tomchick1 as described by Coyle and Henry9 with the addition of a final step in which the enzyme was subjected to gel filtration on a G-200 column. The specific activity of this preparation was 551 nmol product per mg protein per hour incubation. The average recovery of rat liver COMT added to blood samples was  $99\pm1.3\%$  (mean  $\pm$  s.e.m.), and there was no difference in the recovery of exogenously added enzyme from samples with low or high endogenous COMT activity. In addition, when lysed blood samples of high COMT activity were mixed with lysates of low activity, the resultant enzyme activity was the expected arithmetic mean. The distribution of COMT values described here cannot be explained by an increased inhibition or decreased activation of samples with low activity as compared with lysates of high COMT activity, nor is the reverse true of samples with high COMT activity.

The factors that influence the activity of red blood cell COMT in erythrocytes from unselected human subjects are not well understood. The results of our study show that a significant sibling-sibling correlation occurs in RBC COMT activity. Thus, familial factors seem to be important in the regulation of levels of this enzyme in the human erythrocyte. The relative

contributions of heredity and shared environment to these familial factors, and the possible mechanism of inheritance (single gene or polygenic) will have to be determined by family and twin studies. The results of this study also suggest the existence of at least two subgroups of subjects in an unselected population, one with low and one with higher RBC COMI activity.

These results raise the possibility of significant familia differences in enzymatic O-methylation of catecholamines it man. It has been reported previously that the activity of another catecholamine degradative enzyme, monoamine oxidase it human platelets, is subject to genetic control 10,11. The serum activity of the catecholamine biosynthetic enzyme dopamine-\$ hydroxylase (DBH), the enzyme that converts 3,4-dihydroxy phenylethylamine (dopamine) to noradrenaline, is affected by genetic factors. A striking sibling-sibling correlation exists for serum DBH activity12; this correlation is greater in blood samples obtained from monozygotic than in those obtained from dizygotic twin pairs13; and the results of recent studies are compatible with the existence of an autosomal recessive allele for very low serum DBH activity in man with a gene frequency of approximately 20% in the population studied14 The data that have been presented here with regard to a siblingsibling correlation of COMT activity may represent an addi tional example of the importance of familial factors in the regulation of the activities of catecholamine biosynthetic and degradative enzymes in man. Although RBC COMT is bio chemically similar to COMT in other tissues2, the identity o erythrocyte COMT with COMT in other human tissues ha not been established. Further studies will be necessary to deter mine whether the findings reported here bear a relationship to a possible role of catechol-O-methyltransferase in human disease states.

### A reappraisal of human β MSH

A PEPTIDE containing 22 amino acids has been isolated from human pituitaries and, because of its structural resemblance to the octapeptide hormones previously isolated from pig, ox and sheep pituitaries and its similar pigment-dispersing biological activity in lower vertebrates, has been called  $\beta$ -melanocyte stimulating hormone ( $\beta$  MSH)<sup>1</sup>. The discovery and structural analysis of two related sheep pituitary peptides<sup>2.3</sup>  $\beta$ - and  $\gamma$ -lipotrophin ( $\beta$  LPH and  $\gamma$  LPH)<sup>1</sup> which showed that  $\gamma$  LPH comprised the first 1–58 amino acids of  $\beta$  LPH and,  $\beta$  MSH of sheep origin, the 41–58 sequence of both these molecules (Table 1), led Chretien and Li to suggest that  $\beta$  MSH was formed by enzymatic cleavage of  $\beta$  LPH,  $\gamma$  LPH representing the intermediate compound.

It has been shown that the human pituitary contains peptides identical to  $\beta$  lipotrophin and  $\gamma$  lipotrophin<sup>4,5</sup>, and it is evident that 'human  $\beta$  MSH', although it differs in length from the other mammalian  $\beta$  MSHs, is also derived by cleavages of these molecules. The very close correspondence of the human  $\beta$  MSH sequence to the 37–58 region of sheep  $\beta$  LPH (and what is known of the structure of human  $\beta$  LPH (ref. 4)) can be seen in Table 1.

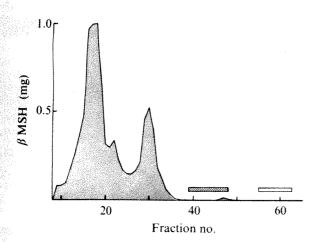

Fig. 1 Fractionation of a human pituitary gland extract on a BioGel P6 column eluted with 1 M acetic acid (column dimensions 90 cm  $\times$  1.5 cm). The shaded area represents  $\beta$  MSH immunoreactive material. The cross-hatched block indicates the elution position of ACTH and the open block that of synthetic human  $\beta$  MSH.

In comparing the  $\beta$  MSHs of the different species, it was apparent to us that as well as its larger size, human  $\beta$  MSH shows other peculiarities not shown by the other mammalian  $\beta$  MSHs. It is more difficult to extract<sup>6</sup> and is localised in the pars listalis rather than the pars intermedia<sup>7</sup>—a lobe which is rudimentary in man. These anomalies have persuaded us that he nature and role of the human  $\beta$  MSH molecule needs a more critical reappraisal. Here we describe our preliminary findings, which seem to throw considerable doubt on the actual existence

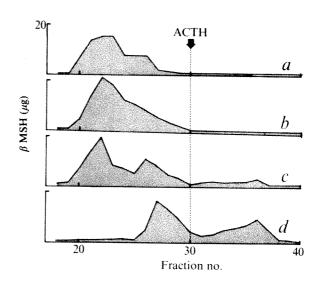

Fig. 2 Samples were removed at timed intervals from a 1 M acetic acid extract of human pituitaries, boiled to prevent further enzyme activity and chromatographed on a BioGel P6 column (90 cm  $\times$  1.5 cm). The distribution of  $\beta$  MSH-like immunoreactive material in each fraction is indicated by the shaded peaks. The vertical dotted line represents the approximate elution position of ACTH, and serves as a marker to show that prolonged extraction in 1 M acetic acid can lead to the formation of  $\beta$  MSH-like material of a smaller molecular size than ACTH.  $\alpha$ , Zero time;  $\beta$ , 0.5 h;  $\alpha$ , 2, h;  $\alpha$ , 16 h.

of human  $\beta$  MSH, and indicate that it may be an artefact of the  $\beta$  LPH molecule formed during certain extraction procedures.

A radioimmunoassay for human  $\beta$  MSH, employing a synthetic human  $\beta$  MSH preparation (CIBA/Giegy) for standardisation and iodination, was developed, and cross-reaction with ACTH and  $\alpha$  MSH was shown to be less than 0.1%. Human  $\beta$  and  $\gamma$  LPH were shown to be equipotent on a molar basis in this assay, and gave curves parallel to the standard.

Human pituitaries (frozen or acetone dried) were extracted in several different ways, assayed, and the extracts applied to Biogel P6 columns and eluted with acetic acid<sup>5</sup>. The pituitaries contained substantial amounts of  $\beta$  MSH immunoreactive material at concentrations corresponding to those reported by Abe and his colleagues<sup>8</sup>. After gel filtration, however, none of the  $\beta$  MSH immunoreactive material behaved as expected for human  $\beta$  MSH, but appeared as high molecular weight material eluting in fractions before ACTH, which has 39 amino acid residues (Fig. 1). Two peaks were identified and further purified by ion-exchange chromatography<sup>5</sup>. The largest molecular weight peak, which predominated in all extracts studied, had an amino acid composition closely resembling  $\beta$  LPH, and the other peptide resembled the NH<sub>2</sub>-terminal 58 amino acid sequence of human  $\beta$  LPH ( $\gamma$  LPH).

Further studies suggested that β MSH was only derived by enzymatic cleavage of these molecules during certain extraction procedures, most commonly those involving the use of dilute

acid. For example, the B LPH in human pituitaries was readily degradable in extracts prepared using 6% acetic acid, unless enzyme activity in the tissue was destroyed by heating or lowering the pH (Fig. 2). A proportion of the degraded fragments resembled human \( \beta \) MSH in their physicochemical properties.

Our interpretation of how B MSH was found in human pituitaries is exceptionally well supported in the literature. It is evident, for example, that the original isolation of human β MSH was made from a side-fraction of a growth hormone extraction procedure1, and it seems quite probable, as a result of the employment of mild extraction conditions to obtain the growth hormone, that degradation of  $\beta$  LPH and  $\gamma$  LPH took place during this or subsequent procedures to form  $\beta$  MSH. Lerner and his colleagues6 have reported several times in the past decade how, if direct extraction of pituitaries is carried out in strong acid conditions (conditions which do not favour proteolysis), human β MSH cannot be isolated.

We have recently been extending our studies to immunoreactive B MSH in human plasmas, samples of which have now been taken from patients with Nelson's syndrome and a normal subject following pyrogen administration. In all cases, the concentrations of \$\beta\$ MSH immunoreactive material were very high, but on gel filtration none of this material eluted in the expected position of human \( \beta \) MSH (Fig. 3). The bulk of immunoactivity resembled β LPH and/or γ LPH in its elution properties, but some was always found in the void volume (a molecular weight of greater than 20,000 was indicated). This latter material may be either an even larger precursor molecule, (such as 'Big ACTH'9), or it may be β LPH non-covalently linked to a plasma protein.

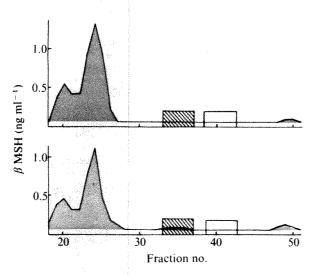

Fig. 3 Fractionation of plasma from two patients with Nelson's syndrome on a BioGel P6/P10 column eluted with frog-Ringer/ albumin buffer. (Column dimensions: P6, 100 cm  $\times$  1 cm, P10, 33 cm  $\times$  1 cm.) The shaded peaks represent  $\beta$  MSH immunoreactive material. The cross-hatched block indicates the elution position of ACTH and the open block that of synthetic human β MSH. Most of the β MSH immunoreactivity eluted in a peak corresponding in molecular size to \( \beta \) LPH.

The stability of β MSH immunoactivity in fresh plasma, thawed plasma or whole blood bears a much closer similarity to the behaviour of β LPH and γ LPH than to synthetic human  $\beta$  MSH, when they are exogenously added to the fluids. The larger peptides are considerably more stable than the B MSH.

In conclusion, our findings suggest that it is likely that radioimmunoassays for human \( \beta \) MSH cannot actually be measuring this hormone, as it does not normally exist. It seems instead that human β MSH radioimmunoassays will be measuring other peptides, the most important of which in pituitary tissue is  $\beta$  lipotrophin, and in plasma, either  $\beta$  LPH or  $\gamma$  LPH. This conclusion readily explains why human B MSH differs so much from the other mammalian  $\beta$  MSHs. It is especially evident that the well-documented association between B MSH and ACTH in man<sup>11</sup> (the two peptides appear to be synthesised and stored in the same pituitary cell and released together in the same physiological or pathological situations) is really an association between \$ LPH and ACTH.

A peptide resembling a true β MSH has been found in extracts of several tumours associated with the ectopic ACTH syndrome<sup>12,13</sup>. On gel filtration, this peptide elutes in the same position as a bovine \( \beta \) MSH standard, but not in the position of the synthetic human  $\beta$  MSH standard. This finding is not unexpected, as it ties in very well with our findings on the other melanophore stimulating hormone, a-MSH, and the 'corticotrophin-like intermediate lobe peptide' (CLIP), both of which are derived by cleavage of ACTH in pituitary pars intermedia cells14, and are also found in tumours associated with the ectopic ACTH syndrome in man15.

We thank the Cancer Research Campaign and Tenovus for support and Professor J. Landon for his help and interest.

### Possible pharmacological and theoretical implications of X-ray structure of the tricyclic antidepressant imipramine

IMIPRAMINE was first shown in 1958 to be effective in the treatment of endogenous depression. It is one of the most widely prescribed members of the tricyclic antidepressant group of compounds which have been chosen for the treatment of the average depressed patient2. It is perhaps surprising that not a single member of this important group of psychotropic drugs has been investigated by X-ray analysis. There is now considerable evidence that a functional abnormality of one or more of the biogenic amine systems of the brain is involved in the aetiology of the depressive or affective disorders. Amines which have been investigated most thoroughly in this respect are noradrenaline and 5-hydroxytryptamine (5-HT). The synaptic action of these putative

Fig. 1 Molecular diagrams of imipramine hydrochloride as determined by X-ray analysis. a, Molecule A; b, molecule B. An asterisk marks the atoms used in torsion angle calculations where an ambiguity in definition occurs. Torsion angle values for A and B are as follows (A is quoted first):  $\tau_1 = 137^{\circ}$ ,  $59^{\circ}$ ;  $\tau_2 = 180^{\circ}$ ,  $161^{\circ}$ ;  $\tau_3 = 174^{\circ}$ ,  $61^{\circ}$ ;  $\tau_4 = 169^{\circ}$ ,  $-172^{\circ}$ .

neurotransmitters is thought to be terminated largely by an active uptake back into the presynaptic nerve ending, and the rat brain is known to possess separate neuronal uptake systems for noradrenaline and 5-HT7. The most striking neurochemical effect of tricyclic antidepressants is their potency in inhibiting these transport processes', and indeed it has been suggested that this effect may be responsible for their clinical ameliorative action. Structure-activity relationships for various imipramine analogues as inhibitors of noradrenaline<sup>8</sup> and 5-HT<sup>10,11</sup> uptake have been reported and recently a possible molecular mechanism for this inhibitory effect has been proposed12. In an attempt, therefore, to gain some insight into the conformational requirements for a compound to be a potent inhibitor of noradrenaline and 5-HT uptake, we are investigating the X-ray structures of a number of tricyclic antidepressants<sup>13</sup>; that of imipramine is reported here.

Well-formed crystals of imipramine hydrochloride, ranging from 0.1-1.5 mm in size in the largest dimension, were grown from a chloroform-xylene mixture. The space-group was uniquely determined as P2<sub>1</sub>/c with eight molecules in the monoclinic cell of dimensions a=11.303 Å, b=29.277 Å, c=14.282 Å,  $\beta=130.91^{\circ}$ , thus requiring two distinct molecules in the crystallographic asymmetric unit. This gives rise to the interesting possibility of two conformations in the solid state structure. Diffractometer data were collected and normalised structure factors (Es) derived. The structure was solved using reflections with  $E \ge 1.2$  by a centrosymmetric multi-solution direct methods program (G. M. Sheldrick, private communication). At present, the conventional R factor is 0.057; complete details of the fully refined structure will be published elsewhere. Figure 1 illustrates the close similarity of the geometry of the tricyclic ring system for the two molecules of the asymmetric unit. The dihedral angle between the planes of the benzene rings is 130° and 123° for molecules A and B, respectively, while the angles between each benzene ring and the plane N-C(methylene)—C(methylene) of the seven-membered ring are 18° and 116° (for A) and 2° and 125° (for B), the latter set of values reflecting the twist in the ring system. The ring nitrogen atom is pyramidal, lying 0.19 Å (for A) and 0.29 Å (for B) from the plane formed by the three carbon atoms to which it is bonded.

The dimethylaminopropyl chains show a definite variation in conformation. The values approximate to a staggered conformation with respect to the N-C(benzene) bonds. From  $\tau_1$  onward, A is almost fully extended, that is, all torsion angles are close to  $\pm$  180°, while B folds back to  $\tau_3$ . In each case the amino nitrogen is hydrogen bonded to a Cl ion 3 Å distant. As the tricyclics are structurally dissimilar to noradrenaline and 5-HT, it is interesting to know what structural and conformational properties enable them to be such potent inhibitors of the neuronal transport of these two putative CNS transmitters. Kinetic studies indicate that they are competitive inhibitors of these uptake systems in the peripheral14 and central nervous systems9 and in blood platelets18, and are, therefore, probably binding to the same site as the endogenous substrates. The most obvious function for the terminal amino group of imipramine is presumably to block the binding site with which the primary amine function of noradrenaline or 5-HT normally interacts12. It is possible that one of the benzene rings of the tricyclic nucleus blocks the binding site usually occupied by the aromatic ring of noradrenaline<sup>12</sup>. Similarly, a larger portion of the tricyclic system may also effectively block the binding site of the indole nucleus of 5-HT. Previous studies18-18 have shown that the most likely conformation of phenylethylamine analogues and catecholamines at the uptake site is very similar to the fully extended trans form which has been shown to be the preferred conformation of noradrenaline in the solid state<sup>19</sup>, in solution<sup>20</sup> and in vacuo by theoretical calculations<sup>21</sup>. A comparison of the distances

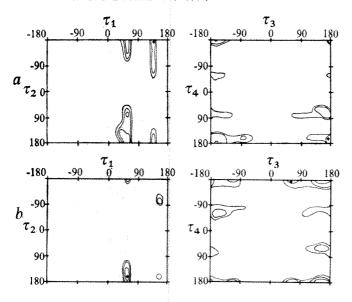

Fig. 2 Potential energy maps for imipramine. a, Molecule A; b, molecule B. Energies were calculated by atom-atom summation of van der Waals interactions as programmed by Motherwell<sup>23</sup>. Contours are at 1 kcalorie mol<sup>-1</sup> intervals and areas not contoured are regions of high energy corresponding to close interatomic approaches and atomic collisions. Heavy crosses indicate the conformations found in the crystal structure.

of the terminal nitrogen atom from the centres of the aromatic rings in both conformations of imipramine with that in noradrenaline19 shows that in the case of conformation B the above proposals12 seem reasonable, although exact coincidence is not attained and may not in fact be necessary. The possibility of conformations other than those found in the crystal, existing in solution can not be excluded (as a recent NMR study of imipramine and its hydrochloride has shown<sup>22</sup>) and a potential energy approach toward this problem has been applied.

Figure 2 shows potential energy maps obtained by varying, in each case, two torsional angles of the molecular side chain whilst the remaining two are fixed, in this particular case, at values observed in the X-ray analysis, to reduce the problem to one in two dimensions. This limitation is not a prerequisite, however, and the same approach can be used iteratively, without any previous assumption of  $\tau$ values, to study the complex arrangement of more than two variables. It is apparent from Fig. 2 that other conformations of similar energy to that of the crystal form could exist, as indicated by a number of minima in the maps other than those corresponding to the crystal position. There seems to be no a priori method of distinguishing which conformation is most likely in the absence of packing constraints (which are important in the crystalline form) and further studies with more rigid tricyclic antidepressants, which are currently underway in our group, may throw light on this problem.

The authors wish to thank Dr R. Abraham for kindly supplying prepublication details of his NMR study of imipramine. O.K. is on the external staff of the Medical Research Council.

### Transcriptional control of α-foetoprotein synthesis in developing mouse liver

α-Foetoprotein (αFP) is a dominant serum protein in many mammalian species during embryonic and early postnatal life It is hardly detectable in the adult body but is often found in an elevated quantity in the serum of individuals with hepatocarcinomas and teratocarcinomas1-5

αFP is synthesised in the yolk sac and foetal liver but it is not known whether the decrease in aFP synthesis in adult liver is due to an alteration in mRNA synthesis or in mRNA translation. To answer this question we have extracted RNAs from polysomes of foetal and adult mouse liver and measured their abilities to direct the synthesis of aFP in cell-free systems. Under the conditions used, the translation of polysomal RNA depends on the presence of high-salt extracts of ribosomes (ribosomal wash) which are known to contain factors involved in the initiation of polypeptide synthesis. It has been possible to determine whether the reason for the reduction in aFP synthesis in adult liver resides in the mRNA fraction or in the ribosomal wash.

Total polysomes were prepared from the liver of adult ICR mice of 14 day foetal mice according to Falvey and Staeheline. RNA was extracted from the polysomes using 1% sodium dodecyl sulphate (SDS) and a mixture of phenol and chloroform?. In some experiments, polysomal RNA was further fractionated by treating the total polysomes with 1% SDS, 5 mM EDTA and 20 mM NaCl followed by sucrose density-gradient centrifugation<sup>8</sup>. RNA sedimenting at 15-20S

Table 1 Synthesis of αFP with ribosomes and high speed supernatant from foetal and adult liver

Ribosome	High speed	Foetal polysomal	αFP
	supernatant	RNA	(c.p.m.)
Foetal	Foetal	+	387
Foetal	Adult	+	411
Adult	Adult		396
Foetal or adult	Foetal or adult	territorial -	93

The components for protein synthesis were described in the legend to Fig. 1. The samples were incubated at 30° C for 60 min and centrifuged at 149,000g for 2 h. Immunoprecipitation was carried out using 500 μl samples as described previously with the following modifications. The reaction was performed in the presence of 1% Triton X-100 and 1% sodium deoxycholate (DOC) to minimise non-specific precipitation 16-18. The samples were then centrifuged through a 0.9 M sucrose cushion containing 1% Triton X-100, 1% DOC and 10 mM each of leucine, valine and phenylalanine. The pellets were dissolved in 1% sodium dodecyl sulphate-4 M urea-1% β-mercaptoethanol at 45° C for 30-60 min and the radioactivity was measured with 10 ml Aquasol (NEN Canada, Montreal, Quebec).

Figures are averages of three assays.

was recovered by precipitation with ethanol and used as 18S RNA. This RNA fraction was enriched with αFP mRNA (K. K., D. W. O., T. I., and T. T., unpublished) as well as albumin mRNA<sup>9-11</sup>. Ribosomal wash was prepared according to Prichard *et al.*<sup>12</sup>. The cell-free systems from the adult mouse liver (adult liver cell-free system) and 14 day foetal liver (foetal liver cell-free system) were prepared as described previously<sup>11</sup>.

Figure 1 shows polyacrylamide gel electrophoretic analysis of proteins produced in the foetal liver cell-free system in the presence of foetal polysomal RNA and foetal ribosomal wash. Four main radioactive fractions were resolved, two of which were comigrating with carrier αFP and albumin, respectively. Additional evidence that they were in fact newly formed αFP and albumin was obtained by immunoprecipitation followed by gel electrophoresis<sup>13,14</sup>. Control samples incubated without polysomal RNA or ribosomal wash showed little radioactivity throughout the gel.

The requirements for  $\alpha FP$  synthesis in the cell-free system were studied by substituting foetal liver components with corresponding preparations from adult liver. In this experiment,  $\alpha FP$  synthesis was assayed by measuring radioactivity in the precipitate formed with antiserum against mouse  $\alpha FP$ . Specificity of the reaction was examined using various control samples and will be published elsewhere. Table 1 shows that substitutions of foetal ribosomes and high speed supernatant fraction with adult counterparts did not affect the synthesis

Table 2 Synthesis of αFP and albumin in the adult liver cell-free system

Exp.	RNA	Ribosomal wash	αFP (c.p.m.)	Albumin (c.p.m.)	αFP/Albumin
I	Foetal	Foetal	335	130	2.6
	Foetal	Adult	201	76	2.6
	Adult	Foetal	54	167	0.3
	Adult	Adult	25	120	0.2
II	Foetal	Foetal	288	126	2.3
	Foetal	Adult	248	83	3.0
	Adult	Foetal	79	147	0.5
	Adult	Adult	66	105	0.6

Conditions for protein synthesis were the same as described in the legend to Fig. 1, except that 'run-off' 80S ribosomes and high speed supernatant were prepared from adult mouse' liver. The adult ribosomal wash was used at 1.5 mg protein ml<sup>-1</sup>. In I and II, the '18S' RNA from foetal and adult polysomal RNA was used at 3.5 A<sub>260</sub> ml<sup>-1</sup>. The samples were incubated at 30° C for 60 min and centrifuged at 149,000g for 2h. The supernatant was removed and divided into two aliquots. One (500 μl) was analysed for αFP as described in the legend to Table 1. The other was analysed for albumin in a similar manner using rabbit antiserum against albumin. Appropriate background counts, obtained in the absence of RNA (95-190 c.p.m.), were subtracted.

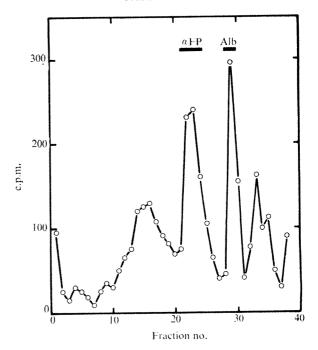

Fig. 1 Polyacrylamide gel electrophoretic analysis of proteins produced in the presence of foetal polysomal RNA in the foetal liver cell-free system. The reaction mixture (3 ml) contained the following (per ml): 2 A<sub>280</sub> foetal 'run-off' 80S ribosomes, 6 mg foetal high-speed supernatant protein, 1 μmol ATP, 0.3 μmol GTP, 10 μmol phosphocreatine, 50 μg mouse liver tRNA, 35 μCi <sup>3</sup>H-leucine (1 Ci mmol<sup>-1</sup>), 10 μCi <sup>3</sup>H-valine (2 Ci mmol<sup>-1</sup>), 10 μCi <sup>3</sup>H-phenylalanine (6.15 Ci mmol<sup>-1</sup>), 25 nmol each of 17 other amino acids, 20 mM Tris-HCl, pH 7.8, 3.5 mM MgCl<sub>2</sub>, 70 mM KCl, 6 mM β-mercaptoethanol, 0.5 mM dithioerythritol, 750 μg foetal ribosomal wash protein and 3.5 A<sub>280</sub> foetal polysomal RNA. The sample was incubated at 30° C for 60 min and centrifuged at 149,000g for 2 h, the supernatant adjusted to pH 4.8 and the precipitate removed. (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> was added to the supernatant to 40% saturation at 0° C and the precipitate was dissolved in 20 mM Tris-HCl (pH 7.8)–150 mM NaCl. This resulted in about fourfold purification of αFP and albumin<sup>11</sup>. Electrophoresis was performed with neuraminidase-treated αFP and albumin as carriers<sup>14.19</sup> and radioactivity was measured as described previously<sup>13,14</sup>. The bars indicate positions of carrier αFP and albumin (Alb).

of  $\alpha FP$ . This suggested that either mRNA or ribosomal wash was responsible for the regulation of  $\alpha FP$  synthesis.

The synthesis of  $\alpha FP$  in the presence of foetal or adult polysomal RNA in combination with foetal or adult ribosomal wash, was therefore examined, using an assay of the synthesis of albumin as an internal control. The results showed that when foetal polysomal RNA was used as a template,  $\alpha FP$  synthesis exceeded albumin synthesis two-to threefold with either foetal or adult ribosomal wash (Table 2). When adult polysomal RNA was used as a template, however, the synthesis of  $\alpha FP$  decreased drastically with either foetal or adult ribosomal wash. Albumin synthesis was relatively unchanged,

Table 3 Synthesis of αFP and albumin in the mouse sarcoma cell-free system

 RNA	Ribosomal wash	αFP (c.p.m.)	Albumin (c.p.m.)	αFP/Albumin	
Foetal	Foetal	308	133	2.3	
Foetal	Adult	365	145	2.5	
Adult	Foetal	263	322	0.8	
Adult	Adult	99	164	0.6	

Conditions for protein synthesis were the same as that described in the legend to Fig. 1, except that 200 μl S-30 of mouse sarcoma 180 replaced 'run-off' 80S ribosomes and high speed supernatant. Both foetal and adult RNA preparations used were total polysomal RNA (3.5  $A_{260}$  ml<sup>-1</sup>). The samples were incubated at 30° C for 2 h and 330 μl post-ribosomal supernatant was used for the assay of αFP or albumin as described in the legend to Table 1. Appropriate background counts, obtained in the absence of RNA (106-225 c.p.m.), were subtracted.

Table 4 Synthesis of αFP and albumin in the presence of nuclear and cytoplasmic RNA from adult mouse liver

RNA	αFP (c.p.m.)	Albumin (c.p.m.)	αFP/Albumin
Nuclear	7	21	0.3
Cytoplasmic	18	184	0.1
Foetal polysomal	217	57	3.8

Assay conditions were the same as described in the legend to Table 3. RNA was used  $3\,A_{250}\,\mathrm{ml}^{-1}$ . Appropriate background counts, obtained in the absence of RNA (105 c.p.m. for  $\alpha$ FP, 156 c.p.m. for albumin), were subtracted.

and as a result, the ratio of aFP synthesis to albumin synthesis decreased to 0.2-0.6. This indicated that aFP mRNA was deficient in the adult polysomal RNA although the factors necessary for its translation were present in adult liver. The counts reported here were relatively low but a series of experiments showed that the results were highly reproducible as shown by two examples in Table 2. Higher counts of aFP have since been obtained by including 3H-glutamic acid in the reaction mixture. This is presumably due to a high content of glutamic acid in aFP (E. F. Zimmerman, unpublished). These results confirm the conclusion stated above.

A similar experiment was conducted in a heterologous cell-free system using an S-30 fraction prepared from mouse sarcoma 18015. Translation of polysomal RNA in this system was also dependent upon the addition of ribosomal wash (K. K., D. W. O., T. I., and T. T., unpublished). Table 3 shows that the synthesis of aFP depended on the source of mRNA but not of ribosomal wash, in agreement with the results obtained with the liver cell-free system.

Although the above experiments indicated the deficiency of active aFP mRNA in the adult liver polysomes the possibility existed that it might be present in the nucleus or in the cytoplasm in a free form. This was tested by fractionating the adult liver into nuclei and cytoplasm, extracting RNA from each fraction and measuring its ability to synthesise aFP and albumin. Table 4 shows that the synthesis of aFP by the nuclear or cytoplasmic RNA was small, suggesting that the level of aFP mRNA in adult liver is in fact greatly reduced.

Another possibility, that aFP mRNA may have been degraded during extraction from adult liver, can be ruled out as albumin mRNA was extracted in an active form from the same source.

We conclude that the synthesis of  $\alpha FP$  in the developing mouse liver is regulated at the level of mRNA. Several steps are involved in the production of mRNA and its appearance in the cytoplasm, for example, transcription, transportation, maturation and the addition of poly(A). Further study is necessary to determine which one of these reactions is responsible for the reduced synthesis of aFP mRNA in adult liver. It is conceivable that such control is relaxed in hepatomas and teratomas, leading to an elevated level of aFP in the serum. Elucidation of the regulatory mechanism involved may thus throw light on the process of malignant transformation as well as normal development.

We thank Kelly Thomas and Irma Schindler for technical assistance. This work was supported by funds from the National Cancer Institute of Canada and the MRC Canada.

### In vitro neoplastic transformation of epithelial cells of rat urinary bladder by nitrosamines

ORAL administration of N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN) selectively induces tumours in the urinary bladder of rats and mice1-3. This organ specificity can be explained to some extent by the metabolic fate of the compound and the carcinogenic effect of its major urinary metabolite on the bladder; Okada and Suzuki4 found that BBN given to a rat was soon excreted as its carboxy derivative, N-butyl-N-(3carboxypropyl)nitrosamine (BCPN). Subsequent tests for carcinogenicity of BCPN showed that it too caused bladder tumour in rats5,6. Furthermore, BBN can be converted to BCPN when incubated with bladder mucosa or liver tissue? These findings suggest that BCPN is responsible for carcinogenesis of the bladder by BBN, or that both BCPN and BBN are directly carcinogenic to bladder epithelium. We have therefore studied the in vitro effect of both BCPN and BBN on

Data in parenthesis shown in series 3 and 8 indicate the results of culture in 0.015 and 0.06% nitrosamine-containing medium, respectively.

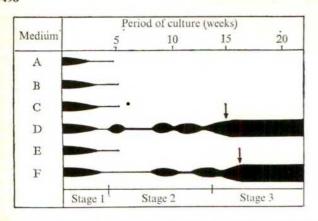

Fig. 1 Growth patterns of epithelial cells of the bladder in various media. Rats were killed by bleeding from the aorta. After terminal ligature of the bladder, about 1 ml of 0.25% trypsin solution containing 0.05% disodium salt of ethylenediaminetetraacetic acid was injected into the bladder lumen. The inflated bladder was separated from the animal and incu-The inflated bladder was separated from the animal and incu-bated in a humidised CO<sub>2</sub> incubator for 45 min at 37° C, and its contents were collected by cutting one end. The bladder was turned inside out and the mucosa was squeezed gently with forceps and washed with 10 ml of Eagle's minimal essential medium (MEM). A combined cell suspension of the contents and the washings of five bladders was transferred to centrifuge tubes, and placed in an ice bath for 3 min to remove sedimented debris and nematode worms. The cells were collected by centrifugation, washed once with MEM and suspended in MEM supplemented with 10% foetal calf serum and 60 μg kanamycin ml<sup>-1</sup> (plain culture medium). Cell suspension containing 300 × 103 cells in 5 ml was inoculated into a square type tissue culture flask (MA 30) which was sealed with a rubber stopper. After culture for 3–4 d at 36° C the medium was replaced by medium A, B, C, D, E or F (described in the legend to Table 1). Nitrosamines were dissolved in physiological saline making 0.3% stock solutions, and urea was dissolved in MEM making 0.5% stock solutions, and urea was dissolved in MEM making 0.5%. solution just before preparation of culture media. Concentrations of nitrosamine and urea in culture media were adjusted to 0.03 and 0.05%, respectively. Each medium was replaced every 7-10 d with the medium of the same constitution as the first. The black area in the figure indicates the apparent growth patterns of epithelial cells in experimental series 3 (see Table 1). The arrow indicates the time of passage.

epithelial cells of rat bladder. In preliminary experiments we had failed to induce growth of these cells, but we found that addition of urea to medium containing a nitrosamine induced growth. We have now established epithelial cell strains from normal cell by culturing them in the presence of BCPN plus urea or BBN plus urea and found that they grow as cancers in syngeneic animals.

Cells were obtained by trypsinisation from bladder mucosa of adult male rats of the inbred ACI/N strain (usually five of the same age for each series of experiments). Cells were cultured in Eagle's minimum essential medium supplemented with 10% foetal calf serum and 60 µg kanamycin ml<sup>-1</sup> (referred to here as plain culture medium) for 3–4 d until they had fixed and spread on the surface of a tissue culture flask. Then the cells were cultured in the presence of urea or BCPN or BBN or a nitrosamine plus urea without removing these compounds from the medium until the cell strain was established. In plain culture medium epithelial cells became polynuclear

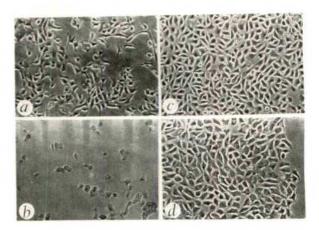

Fig. 2 Culture of cells in medium containing nitrosamine and urea. a, Initial cell growth in medium containing BCPN and urea at 5 weeks; b, degeneration of the cells at 6 weeks; c, cell strains established by BCPN and urea (BES3P) and (d) by BBN and urea (BES3B). (Phase contrast,  $\times$ 100.)

and died after 4-5 weeks (Fig. 1). In medium containing urea alone or a nitrosamine alone the fate of the cells was similar. In medium containing urea and BCPN or urea and BBN some cells survived for 4-8 weeks, although many died during this period (stage 1). The surviving cells started to divide after this latent period (Fig. 2a) and formed one or two colonies per flask. When a focal monolayer formed, many cells died in 1-2 weeks (Fig. 2b) (this is referred to here as contact death), but a few cells survived and divided again. This process was repeated two or three times (stage 2), and finally cells grew without contact death to form a confluent monolayer (stage 3). Usually it took 13-15 weeks for cells to reach the final stage. Confluent cells were trypsinised and passed to other flasks, thus establishing cell strains amenable to serial passage. Attempts to passage stage 2 cells, by trypsinisation or by scraping with a rubber policeman, resulted in rapid degeneration of the cells in a new flask. If medium containing both

Cells, which had been kept by serial passages and by continuous culture in the medium containing nitrosamine and urea or urea alone, were cultured in several large flasks containing plain culture medium until they formed a confluent monolayer. Cells obtained by trypsinisation were suspended in Eagle's medium and counted. A known number of cells was injected into 8–9-week-old male ACI/N rats, some of them already irradiated with 300 r. The recipients were killed when tumours reached appropriate sizes for examination. Animals which did not develop tumours were observed until 200 d after transplantation. Cell strains are named as follows: BE means they derived from bladder epithelial cells; S number denotes the experimental series number, and the last character shows the drug added in the medium, that P, BCPN plus urea B, BBN plus urea; U, urea alone. i.p., intraperitoneal; s.c., subcutaneous; i.b., into bladder wall.

urea and nitrosamine was changed to plain culture medium at this stage, all cells died in several weeks without further growth, whereas cells in stage 3 or cells of the established strains could grow even in plain culture medium. Large fibroblast-like cells, which were always present with epithelial cells in the early stage of culture, grew to some extent, but always degenerated gradually and after 10 weeks few were detectable. Thus established cell strains consisted of pure epithelial cells (Fig. 2c and d).

Table 1 summarises the results of a similar experiment. In each series of experiments the fate of cells cultured in the media corresponding to those described above was similar to that shown in Fig. 1. Only cells from 39-week-old rats (series 8), however, continued to grow in medium containing urea alone. In this case the start of growth, 10 weeks after inoculation, was delayed relative to that of cells cultured in medium containing both urea and a nitrosamine but a confluent monolayer gradually formed. Cells of all established strains listed in Table 2 had epithelial shape and orientation, and most of them had more than two relatively large nucleoli, compared with normal epithelial bladder cells which have one or two such nucleoli. Modal chromosome numbers of the cell strains varied from 70 to 80 except BES3P strain whose modal number was 42. The tendency of cells to pile up in a monolayer was rarely demonstrated.

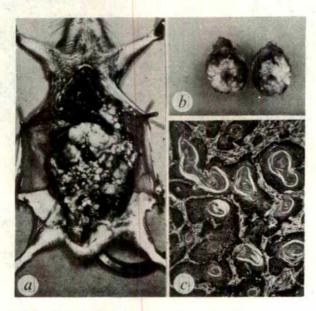

Fig. 3 Tumours developed from BES3B cells by intraperitoneal injection (a) and by intrabladder-wall injection (b), and histology of the tumour (c). (Haematoxylin and eosin,  $\times$  50.)

Tumorigenicity of cells of the established strains was tested by injecting them into adult ACI/N male rats, some of which had been X irradiated on the previous day (Table 2). All cell strains induced in medium containing both urea and a nitrosamine and one strain in medium containing urea alone gave rise to tumours, after injection subcutaneously, intraperitoneally or into the wall of the bladder. In 1-3 months the tumours grew to a palpable size. All tumours contained areas of squamous metaplasia, histologically designated squamous cell carcinoma. Tumour cells were arranged in a cystic or papillary form, containing a keratin pearl (Fig. 3c). Intraperitoneal BES3B, BES8B or BES8P cells gave rise to many tumour nodules in the peritoneal cavity of recipients (Fig. 3a), some causing death. Tumours produced by injection of cells were serially transplantable into untreated syngenic rats.

Our results show that epithelial cells of the urinary bladder of adult rats transform into neoplastic cells when treated with urea combined with either BCPN or BBN. Because fibroblast-like cells did not grow, nitrosamine plus urea must

affect epithelial cells specifically. This recalls the in vivo carcinogenesis of the bladder when BBN or BCPN induced very few tumours originating from cells other than epithelial cells \$1.5. Our experimental system is unique in the following ways. (1) The culture conditions reflect the in vivo condition for induction of bladder tumour by BBN-the concentration of nitrosamine in the medium is comparable with that of BCPN excreted in the urine when a carcinogenic concentration of BBN is administered in the drinking water (our unpublished data). Target cells are exposed continuously to nitrosamine as with in vivo carcinogenesis and urea is present in the medium. (2) Cell donors are adult animals and target cells come from the primary cultures, and not foetal or newborn animals as in previous experiments8. (3) Cells of the established strains develop cancers in untreated adult animals.

### Effect of split doses of X rays on neoplastic transformation of single cells

Using cloned hamster embryo cells in culture, we have found that if an X-ray dose is divided into two fractions, more neoplastic transformations occur than if the same dose is given in a single exposure. This could have important implications for radiation protection, where in general radiation is accumulated in a number of small fractions rather than in a

single large exposure.

We used the in vitro system1.2, in which primary or secondary cultures of hamster embryo cells are seeded at low density to allow for clone formation. More cells are seeded as the dose increases to account for cell killing. Twenty-four hours elapse between plating and irradiation, in order for cells to attach, after which cultures are incubated in a humidified atmosphere of 5% CO<sub>2</sub> in air for 9-10 d. They are then fixed, stained and examined for the presence of transformed clones, which can be distinguished morphologically from controls. The transformed cells show ·a loss of contact inhibition3, and pile up randomly, in contrast to normal cells1,2,4-6 (Fig. 1). We have described the relationship between the morphology of the transformed cells and their tumorigenicity in vivo1.2; when injected into 2-3-week-old hamsters they give rise to fibrosarcomas (Fig. 2). Their ability to grow in semi-solid medium and in suspension, and their agglutinability by plant lectins have served as further criteria for transformation2.

Using this model system, we have elucidated the doseresponse relationship for transformation by single acute doses of X rays between 1 and 600 rad<sup>2</sup>. The overall shape of the curve resembled that commonly observed for the production of tumours in experimental animals<sup>7</sup>, namely a rising transformation rate with doses from 1 to 150 rad, followed by a plateau between 150 and 300 rad, after which a further increase of dose resulted in a decrease in the proportion of colonies transformed. This decrease coincided with doses such that the number of

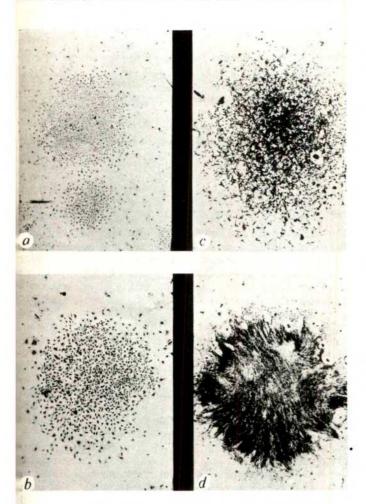

Fig. 1 a and b, 9-d-old clones of normal embryo cells (Giemsa × 10.6); c and d, two representative 9-d-old clones of hamster embryo cells transformed in vitro by a split dose of 75 rad (Giemsa × 10.6).

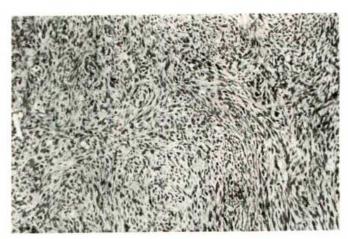

Fig. 2 Histological section of a non-invasive, non-metastasising fibrosarcoma growing in a 3-week-old hamster 10 d after a subcutaneous injection of 10<sup>6</sup> transformed cells obtained as follows. A transformed clone, of the type illustrated in Fig. 1c, produced by X irradiation of single cells, was isolated and grown up through 30 passages before inoculation (haemotoxylin and eosin × 106).

cells killed began to be significant. Our system inherently accounts for cell killing, however, because transformation is scored from among surviving colonies. Consequently, potentially transformable cells seemed more sensitive to the lethal effects of the accumulated damage at the higher doses.

We next pursued the problem of dose protraction since the problems of risk estimates for radiation are related to increments of low doses protracted over long periods, rather than a single acute exposure. For this reason, a single dose of 50 rad was compared with two doses of 25 rad 5 h apart. The doses were chosen to be on the ascending portion of the dose-response curve, while the time interval was a compromise, being long enough to allow for the repair of sublethal radiation damage, but short enough to minimise the probability of cell division between exposures. Plates receiving the single dose were exposed at a time mid-way between the delivery of the first and second doses to the plates. In later experiments the effect of a dose of 75 rad was compared with that of two doses of 37.5 rad 5 h apart.

The results are presented in detail in Table 1, summarised in Table 2 and plotted in Fig. 3. For both 50 and 75 rad, there is a clear increase in the proportion of transformed clones for doses delivered as two fractions compared with the same doses given as single exposures.

	Table 2 Po	oled data	
	Clones counted	No. transformed	% Transformation
Control	38,210		mannaer
75 rad	25,882	160	0.62
$(37.5 \times 2)$	23,762	255	1.08
50 rad	14,272	27	0.19
$(25 \times 2)$ rad	15,582	55	0.35

To check whether the presence of feeder cells was essential for the production of transformed clones, some cells in these experiments were plated on feeder layers and others were not. While the feeder layer (at levels of  $2 \times 10^4$  cells per 60-mm Petri dish) improved plating efficiency, it did not affect the proportion of cells transformed by the radiation.

At these low doses less than 10% of cells were killed, as can be seen from the surviving fractions listed in Table 1. It is also evident from Table 1 that more cells survived split doses than single doses, which shows that sublethal damage was repaired, as in almost every biological system studied.

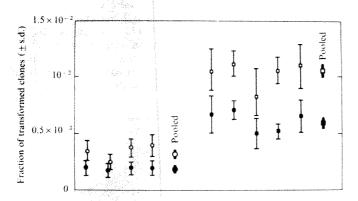

Fig. 3 Incidence of cell transformation in cloned cultures of hamster embryo cells. Four replicate experiments were performed in which the effect of a single dose of 50 rad (●) was compared with that of two doses of 25 rad (○). The results of the individual experiments are shown, together with the pooled data; vertical bars are standard deviations. The consequence of a single dose of 75 rad ( ) compared with two doses of 37.5 rad ( ) are shown.

The results suggest that even at these low doses there is a strong correlation between the proportions of cells killed and transformed. When a dose of radiation is delivered as two fractions fewer cells receive lethal injury, and therefore more cells sustain sublethal damage than when the same dose is delivered in a single exposure. Since X-ray transformation presumably involves sublethal events, it is not surprising that splitting the dose leads to less killing but enhanced transformation.

Comparison of our in vitro data with similar studies of tumour induction in vivo is interesting, although the latter show no clear-cut pattern. Most studies of tumour induction in animals have involved larger doses and longer time intervals than used in our study, and leukaemias and lymphomas rather than solid tumours. Kaplan and Brown<sup>8,9</sup> found that 475 r., given to mice as four exposures at 4 or 8-d intervals, was more tumorgenic than the same dose given as a single exposure or in daily fractions. By contrast, Metalli et al. 10 concluded that split doses of sublethal irradiation with short fractionation intervals are less efficient inducers of tumours and leukaemias than a single dose. Upton et al. found a complex pattern of X-rayinduced myeloid leukaemia in mice11 that was intermediate between these two sets of results.

Our demonstration of an increased incidence of transformation when the dose is divided, albeit with an in vitro system, is germane to the problems of radiation protection. When radiation workers and the general public are exposed to ionising radiation it is usually in the form of multiple small doses rather than a single large dose, as commonly used for experimental studies with small animals. For most end-points observed, including cell killing, fractionation reduces the effect of a given dose of radiation, but if the opposite is true for transformation ours will be an important observation in practical terms.

### Association of polyanion resistance with tumorigenicity and other properties in BHK/21 cells

QUIESCENT, non-growing cultures of normal fibroblasts may arise as a result of absence of anchorage1.2 or deprivation either of serum macromolecules3-5 or of a variety of nutrients8. This state can also be induced by sulphated polysaccharides", and we have reported the inhibition of growth of normal BHK/21 hamster fibroblasts in monolayer by dextran sulphate and heparin9 and the protection against this inhibition by purines10. Goto et al. have also found that dextran sulphate added to grow ing cultures markedly reduces the saturation density of established lines not transformed by viruses, but not that of primary embryonic fibroblasts<sup>11</sup>. The ability of many cells to grow in agar only after transformation with tumour viruses has been similarly ascribed to the inhibitory effects of sulphated polysaccharides8,12 and a close quantitative relationship has been reported between tumorigenicity and plating efficiency in agar<sup>18</sup>.

. In the light of these findings and the known existence of sulphated polysaccharides and proteoglycans in connective tissue, it is appropriate to seek a role for such polyanions in growth control in such tissues. We have obtained dextran sulphate resistant cultures of normal hamster BHK/21 cells and studied their properties. The results show that there is a close correlation between resistance of clonal sublines to dextran sulphate and a number of other properties: high

Table 1 Clonal variants of BHK/21 cells (see text) compared with parent untransformed and transformed with polyoma virus (PY)

	•	,	• • • • • • • • • • • • • • • • • • • •

Figures in brackets refer to number of sublines tested. Tumorigenicity was tested by injecting 0.5 ml cell suspension subcutaneously into young adult hamsters (four animals per suspension) containing 10<sup>2</sup>, 10<sup>3</sup>, 10<sup>4</sup>, 10<sup>5</sup> cells; animals were observed for 5 months. The inhibitory concentration of dextran sulphate was that which prevented the doubling of cells in 4 d (Fig. 1). Serum independence is the ability to grow continuously in serum-free HEMP medium (E4, 4 volumes; Hams F12, 1 volume; Pirts, 1 volume); methocel<sup>10</sup> (4,000 c.p.s. Dow Chemical Corp.) to 0.2%; dextran sulphate to 10 µg ml<sup>-1</sup>.

\*Cells pile up in the centre of large colonies, but show orientation at periphery. †Cells attach initially but later grow in suspension. ‡Clarke, G. D., and Ryan, P. R. (unpublished) and Bush<sup>18</sup>.

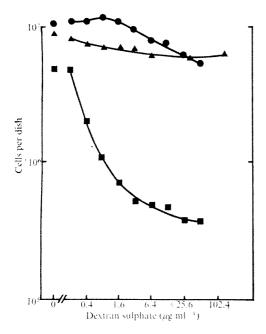

Fig. 1 Cells were grown in duplicate dishes of E4 medium containing 5% serum from an inoculum of  $3\times10^{6}$  per 5 cm dish at 37° C for 4 d. After removal with trypsin versene they were counted with a Coulter Electronic Counter. , Original BHK/21 cells; , BHK/21 cells transformed with polyoma virus and, A, clonal subline 'R-type'. Points are means of duplicates.

tumorigenicity, serum independence and growth in suspension. While the growth of normal BHK/21 cells is completely inhibited by 2 µg ml<sup>-1</sup> dextran sulphate, that of polyoma transformed cells is only marginally affected by 50 µg ml<sup>-1</sup> (Fig. 1).

To select for resistant variants, therefore, normal cells were seeded at 3  $\times$  10<sup>5</sup> per dish in medium containing 5% serum and 0.5 μg ml<sup>-1</sup> dextran sulphate. Dishes were incubated at 37° C until a dense culture was obtained. Subculture was then made at one-tenth dilution into both 0.5 and 1.0 µg ml<sup>-1</sup> dextran sulphate. This regime of subculture at twofold higher concentrations was continued reverting to the same concentration only when inadequate growth was obtained at the higher, until cells were growing vigorously at 16 µg ml<sup>-1</sup> of dextran sulphate. Growth was continued in this medium with progressively decreasing inocula until cells grew reproducibly from 104 per 9 cm dish. This complete selection process was repeated three times and, on two occasions, the cells were then cloned in dextran sulphate-free medium with 10% serum (plating efficiency 25–30%). In the course of each selection it was noted that giant cells appeared, most of which floated or remained loosely attached to the dish; aliquots from the supernatant were always, therefore, incorporated in subcultures. After a few passages in dextran sulphate the cells lost the distinctive oriented appearance of BHK/21 and, in later passages, many remained rounded with apparently healthy cells appearing in suspension. This behaviour was also shown in dextran-free medium. From the resistant cells colonies produced were classified in three groups. Most colonies were composed of spread cells initially and showed central piling up. Sublines from such clones ('I-type') showed variable resistance to dextran sulphate and 102-103 cells injected into hamsters formed tumours in 50% of animals (TD<sub>50</sub>). One colony resembled the original cells, showing oriented growth and full sensitivity to dextran sulphate ('S-type').

BHK/21 cells seeded at  $3 \times 10^5$  cells per 5 cm dish in E4 medium containing 0.5% serum and incubated for 3 d. Medium was removed, duplicate dishes treated at room temperature for 1 min with either E4 or E4 + dextran sulphate (Medium A). Dishes were then washed with E4 (two, three and four washes were used and results were not significantly different) and incubated for 20 h with E4 medium or E4 + 3% serum (Medium B) and 3H-thymidine at 1 μCi ml<sup>-1</sup>. Following autoradiography the percentage of labelled nuclei was calculated from 300 in each of four dishes per set.

Nine colonies ('R-type') consisted almost entirely of rounded cells and sublines from these all had a TD<sub>50</sub> as low as that of polyoma transformed BHK/21 cells and were also as resistant to dextran sulphate (Table 1 and Fig. 1). It was further found that all nine sublines were capable of continuous propagation without serum in a complete synthetic medium. A further 15 'Rtype' sublines were established from clones arising in medium containing 16 µg ml<sup>-1</sup> of dextran sulphate (plating efficiency 0.5-2%) all of which grew continuously in serum-free medium. Temin suggested that sulphated polysaccharides might act by combining with serum growth factors and indeed a small precipitate containing protein occurs in dextran sulphate medium and adheres to the dish (R. C. Hallowes, unpublished). Our results, however, indicate that quiescent BHK/21 cells can also react with dextran sulphate in the absence of serum in a manner that, even after thorough washing, inhibits their response to serum (Table 2), indicating that it also binds to the

In view of the tendency of dextran sulphate resistant cells to grow in suspension and the observation of floating cells in dextran sulphate containing medium some hours after seeding, the effect of the polyanion on attachment of cells to dishes was

### The Interpretations of Multiple Observations

F. H. C. Marriott

November 1974, x+118 pp., £3.50/\$9.00.

0.12.473450.2

There are two main stages at which mistakes occur in the numerical analysis of multivariate datain the choice of a particular method of analysis, and in the interpretation of the results thereby gained. The book provides a critical examination of the most important available numerical methods, gained. The book provides a critical examination of the inost important available indirectal methods, relating them to the types of data for which they are suitable, explaining the questions they are trying to answer and the assumptions they involve. In discussing the classical techniques of discriminant analysis, factor analysis, principal components and canonical analysis, and more recent developments in the fields of cluster analysis and scaling methods, stress is laid on the practical aspects of the examined methods, while mathematics is kept to a minimum. This work will be of great value to all scientists needing to analyse multivariate data, including biologists, geologists, soil scientists, psychologists and biomathematicians.

Here are the second and third volumes in this critical review of the organometallic compounds of all the elements, compounds which are attracting increasing interest all over the world. In these reference volumes the author takes account of the international literature on the subject up to the end of 1972. These volumes cover elements from Group 4A and Group 4B: Volume 2 includes a major chapter on silicon and a minor chapter on titanium, zirconium and hafnium, while Volume 3 deals with germanium, tin and lead. Each chapter provides a complete review of all aspects of the organocompound in question, together with critical comments on the relative importance ments and demerits of the methods of analysis applicable.

### The Physical Chemistry of Dye Adsorption

I. D. Rattee and M. M. Breuer

November 1974, xiv+324 pp., £8.60/\$22.25.

0.12.582550.1

Here is an up-to-date work which brings together important information on experimental data produced by current research and relates it to general scientific knowledge regarding surface phenomena. Thus it is able to present a more unified approach to the dye adsorption process than have previous books on the subject, at the same time defining more clearly the role played by research in relation to technological demands. This leads to a treatment which is much more informative to the research chemist and enables the main investigation groups in general science, medical and dye/textile polymer research, to be considered together. This volume should appeal to a wide audience—including students and researchers in cosmetic, colour, textile and polymer chemistry, surface and colloid chemistry, histology, food science, medicine and ecology and in many other areas concerned with interfacial phenomena.

Cells were removed from a culture in E4 medium containing 20% calf serum with 0.05 % trypsin (Difco 1:250) in 0.1 % versene, washed with medium and resuspended in the same medium containing only 5 mM NaHCO<sub>3</sub> and with 30 mM HEPES buffer adjusted to pH 7.0. Aliquots of the same medium (5 ml) were prepared with serum and dextran sulphate as indicated and warmed to 37° C. Cells were seeded into these at  $6\times10^{6}$  each and 2.5 ml of each suspension dispersed into duplicate dishes in a 37° C room. After 20 min the supernatant medium was gently poured off into plastic pots. The dishes were then gently washed with a further 2.5 ml of medium containing 10% serum and the washings added to the pots. Cell numbers were counted in each suspension with a Coulter Electronic Counter and the numbers attached calculated.

examined; Table 3 shows that the attachment of both normal and transformed cells is inhibited in the presence of serum. This behaviour is in line with the observation that mouse L cells in monolayer culture detach from the dish within 10 min on the addition of dextran sulphate<sup>14</sup>.

It is premature to attempt a detailed understanding of the mechanism of inhibition by, and resistance to, dextran sulphate. The simplest hypothesis, that polyanions by competition for cell attachment sites inhibit anchorage which is essential for growth of normal but not transformed cells, is untenable. The inhibition of attachment of BHK/21 cells by dextran sulphate in short term experiments described in Table 3 demonstrates a delay but within a few hours the majority of cells are attached and spread. Moreover, in the absence of polyanions, such cells can grow in suspension.

Our observations with these variants suggest that resistance to dextran sulphate is correlated with a tendency to grow in suspension, independence of serum growth factors and high tumorigenicity. We postulate that dextran sulphate, which is known to react with many proteins<sup>15</sup>, binds to the cell membrane so as to block the interaction with the macromolecular growth factors in serum and to block temporarily the interaction with the solid substrate. The membrane functions involved are probably required for the growth of normal but not that of transformed fibroblasts. The selection process in dextran sulphate under which resistant cells emerge may thus be considered as comparable with that under which malignancy emerges in vivo. It is not yet clear whether the process is analagous, namely whether sulphated polyanions of connective tissue mediate the control of cell proliferation in those tissues. Meanwhile it is important to know whether the phenomena reported here can be observed also in other cell systems.

### Antibody-dependent cell-mediated damage to schistosomula in vitro

ANTIBODY-DEPENDENT cell-mediated cytotoxic effects have been described in many in vitro models involving single-cell suspensions of maminalian or avian target cells, and could be important in the rejection of tumours and allografts<sup>1-6</sup>. Similar responses could also be involved in protective immunity against metazoan parasites, and evidence for cell-mediated effector mechanisms of various types has emerged from work on Nippostrongylus braziliensis<sup>7</sup> and Litomosoides carinii<sup>8</sup> in rats. Here we present two new aspects of cell-mediated responses to metazoan parasites. First, we have adapted the 51Cr-release technique to assay damage to schistosomula of Schistosoma mansoni in vitro. Second, we provide evidence that normal human peripheral blood leukocytes, in the presence of sera from patients infected with S. mansoni, can damage labelled schistosomula in the absence of added complement.

A naturally-infected field population of Biomphalaria pfeifferi was used to initiate a laboratory colony of S. mansoni, which was subsequently maintained in locally collected snails and Swiss albino outbred mice. Schistosomula were prepared from cercariae by a modified skin penetration technique9, and were stored at 4°C overnight in Hanks' balanced salt solution containing antibiotics and lactalbumin hydrolysate 0.5%, together with 10% heat-inactivated normal baboon serum. This storage procedure was not associated with a detectable loss of schistosomula or decrease in viability, as judged by motility and ability to metabolise fluorescein dibutyrate<sup>10</sup>. After overnight storage, most of the supernatant fluid was removed, and the organisms, after resuspension in the residual supernatant, were labelled with 51Cr-sodium chromate (Radiochemical Centre, Amersham). Incubation of 104 organisms with 0.5 to 1 mCi of <sup>51</sup>Cr in a volume of less than 0.5 ml for 3-4 h at 37° C gave count rates of 50-300 c.p.s. per 100 organisms. Labelled schistosomula were washed five times in HEPES-buffered Eagle's minimal essential medium (MEM) with antibiotics, and were resuspended at 500 or 1,000 organisms per ml in MEM containing 10% heat-inactivated foetal calf serum (MEM/FCS).

Serum samples were obtained from patients with a long history of presumptive exposure to S. mansoni and with eggs detectable in varying numbers in the faeces by the Kato technique11. Control samples were taken from laboratory workers with no known exposure to S. mansoni. All sera were heatinactivated and were diluted in MEM/FCS before testing. Peripheral blood leukocytes were prepared from uninfected human subjects by defibrination and centrifugation over Ficoll-Hypaque<sup>12</sup>. Interface cells were washed twice in MEM and resuspended in MEM/FCS at varying cell concentrations. Such preparations contained both polymorphonuclear and mononuclear leukocytes.

The cytotoxicity test was carried out in a total volume of 0.3 ml in 38×7 mm sterile plastic tubes, incubated in humidified plastic boxes. At the end of the incubation period, 0.15 ml of the

Final dilution of serum in the cytotoxicity assay mixture.

supernatant was removed, and both cell and supernatant tubes were counted for <sup>51</sup>Cr. Four replicates for each group were set up, and results are expressed as the geometric mean of the original percentage isotope release values. The logarithmically-transformed data were tested by multifactorial analysis of variance followed by Duncan's multiple range tests<sup>12</sup>, and a summary of the statistical analysis is given for each set of data.

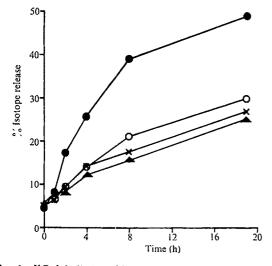

Fig. 1 <sup>31</sup>Cr-labelled schistosomula were incubated for varying periods of time in the presence of: ▲, medium alone; ×, serum alone (A39/1 at 1/30 final concentration); ○, cells alone (multiplicity of 2,000:1); ④, cells+serum. Analysis of variance: 'effector preparation' × 'time' interaction, P<0.001 (F=4.54:15 and 72 degrees of freedom). Multiple range tests: 'Cells+serum' different from other preparations at 2, 4, 8 and 19 h (P<0.05); 'Cells alone' different from 'medium alone' at 8 h (P<0.05).

The time course of isotope release in the presence of various combinations of serum from an infected patient and normal cells is shown in Fig. 1. Release in the presence of medium alone was slow, amounting to only 25% after 19 h. Antibody alone, at a final concentration of 1:30, caused no significant increase in isotope release. Cells alone, at a multiplicity of 2,000:1 to the target organisms, caused a slight increase in isotope release. This multiplicity was chosen arbitrarily, and it should be borne in mind that the target is a large multicellular organism measuring approximately  $400 \times 100~\mu m$ . In later experiments, significant cytotoxicity by cells and antibody was found at multiplicities down to 100:1. Cells in combination with antibody caused a marked increase in isotope release which was

significantly different from the effect of cells alone from 2 h of incubation onwards. By 19 h, isotope release in the presence of cells and antibody was beginning to show a plateau effect at approximately 50%, and in separate experiments it was observed that only 50–60% of the total isotope incorporated could be released by repeated freezing and thawing in hypotonic solution, a procedure which killed 100% of the schistosomula. This presumably reflects the multicellular nature of the organism, which may be resistant to complete disruption. The relationship between isotope release and death of the organism was difficult to determine, but incubation of various preparations of schistosomula with fluorescein dibutyrate<sup>10</sup> and subsequent examination by fluorescence microscopy showed that the percentage of isotope released in a preparation was approximately related to the proportion of organisms that were immobile and that failed to metabolise the fluorescein ester.

The data in Fig. 1 were derived from a single serum sample at a single dilution. Table 1 shows the results of an experiment in which four sera from infected subjects and four sera from control subjects were tested at three dilutions. In separate experiments, a total of eleven test sera and four control sera were examined. None of the sera was toxic for schistosomula in the absence of added leukocytes. All the test sera showed significant effects in the presence of added cells, in seven cases at dilutions down to 1:96. Later examination of three of the positive sera (A40/1, A38/3 and A39/1) showed that significant effects could be obtained at dilutions down to 1:320. None of the control sera showed a significant effect, even at concentrations as high as 1:6.

These results indicate that schistosomula can be damaged in vitro by normal human peripheral blood leukocytes together with sera from infected patients, but not with sera from control subjects. Unlike "lethal antibody" and granulocyte-mediated damage to opsonised organisms<sup>13</sup>, both of which depend on the presence of large amounts of added complement, the effect described here is complement-independent, in that heat-inactivated sera were used throughout. An analysis of the antibody and cell types responsible for eliciting the effect will be published elsewhere (A. E. B., unpublished): preliminary observations indicate that maximum cytotoxic activity is associated with an eosinophil-rich polymorphonuclear leukocyte fraction.

The relevance of the observations to resistance to reinfection cannot at present be established, particularly as it has not yet been demonstrated clearly that human patients do develop an effective immunity to *S. mansoni*. Recent evidence in experimental schistosomiasis in rats, however, has shown that resistance to infection can be transferred to normal animals by injection of immune serum, but that irradiation of immune rats

<sup>\*</sup> Measured after 14 hours.

<sup>†</sup> Schistosomula were cultured either with or without effector cells at a multiplicity of 2,000:1.

<sup>§</sup> Schistosomula cultured with or without effector cells, without added serum.

on the day of cercarial challenge abolishes immunity<sup>14</sup>. These findings suggest that both antibody and a radiosensitive cell may be involved in resistance in rats. Our results indicate that a similar mechanism could be effective in man, and provide a technique for analysing the response in more detail.

#### C3 activation and T-independent B cell stimulation

Some highly polymerised immunogens with repeated antigenic determinants, such as bacterial polysaccharides or polymerised flagellin and hapten conjugates of these, can stimulate mouse B lymphocytes to make antibody without requiring the cooperative helper activity of T lymphocytes1. The mechanism whereby such T-independent immunogens, after interaction with the surface receptors on specifically responsive B lymphocytes, trigger these into activity is uncertain. Dukor and Hartmann<sup>2</sup> have postulated that binding of activated C3 to complement receptors on B cells acts as a necessary second signal for antibody production. They envisage that T-independent antigens and B-cell mitogens generate this second signal by their ability to activate C3 through the 'bypass' pathway, whereas in the case of T-dependent antigens the signal derives from C3 cleavage by proteases released by activated T cells.

Recent work in our laboratory suggests that neither high epitope density3 nor polyclonal mitogenicity17 are adequate explanations for T cell independent immune induction. Here we extend these observations by examining the correlation between the immunogenic properties of various antigens tested in vivo and their capacity to activate mouse C3 in vitro. On the basis of the above model, all T-independent antigens should be able to activate C3.

Fresh C3H/He mouse serum was used as a source of C3 and the origins of the antigens are listed in Table 1. Sheep anti-mouse C3 serum was made by a modification of the method of Mardiney and Müller-Eberhard<sup>12</sup>. For C3 cleavage, 0.05 ml of the test sample in saline was added to 0.1 ml of fresh mouse serum diluted with an equal volume of Veronal buffered saline12 containing 0.025 M MgCl<sub>2</sub> and 0.025 M ethyleneglycol bis-(aminoethyl)-tetraacetic acid (EGTA) (Koch-Light). The mixture was incubated at 37° C for 45 min. The presence of cleavage products was detected by antigen-antibody crossed electrophoresis<sup>14</sup> in agarose gel containing 0.01 M EDTA and sheep anti-mouse C3 serum.

The presence of EGTA and Mg2+ during incubation provided conditions for activation of complement by the 'bypass' mechanism only<sup>15,16</sup>, and excluded any activation by the Ca<sup>2+</sup>dependent classical pathway because of pre-existing antibody reacting with the antigen. The sensitivity of the method for detecting activation of C3 was tested using various concentrations of Escherichia coli 0.55:B5 lipopolysaccharide (LPS) (Difco) and levan (Fig. 1). LPS was detectably active at concentrations down to 2 µg ml<sup>-1</sup> (although this is not visible in the photograph) and obvious activation was obtained at 4 μg ml<sup>-1</sup>; the preparation of levan was clearly active at 1 µg ml<sup>-1</sup> and some activation was detected at the lowest concentration tested  $(0.5 \mu g ml^{-1}).$ 

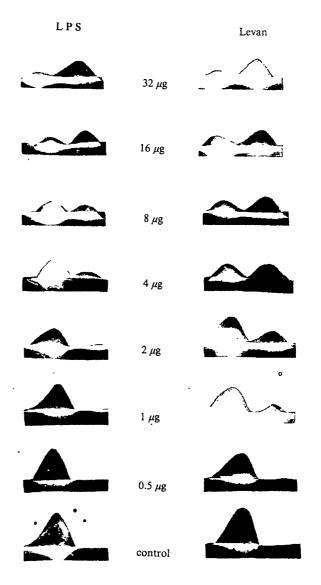

Fig. 1 Comparison by antigen-antibody crossed electrophoresis of C3 activation by various doses of *E. coli* 0.55:B5 LPS and levan. The left hand peak is native C3, the right hand (faster moving) its cleaved product (anode on the right).

<sup>\*</sup>Cobra venom factor was prepared from Naja naja (ref. 9)

Most of the antigens and mitogens were tested at a relatively high concentration (400 µg ml<sup>-1</sup> of incubated mixture). Some were also tested at lower and higher concentrations as shown in Table 1. Cobra venom factor (CoF), various preparations of LPS (except from Salmonella mR 345), levan and DNP 50 BSA activated C3. Type III pneumococcal polysaccharide (SIII), hyaluronic acid, polyglutamic acid and DNP, BSA were inactive. DNP conjugates of various polymers (which are all immunogenic with respect to the DNP moiety11,17) behaved in the same way as the polymers themselves. Treatment of LPS with mild acid or alkali which abolishes its mitogenicity (G.G.B.K., unpublished) also abolished its C3 activating properties.

Table 2 lists the C3 activation produced by various antigen preparations whose mitogenic activity has been examined in the presence of foetal calf serum<sup>17</sup>. There is no apparent correlation between mitogenic and C3 cleaving activity. For example, levan which activates C3 very efficiently (Fig. 1) is a less potent 'mitogen' than SIII which did not activate C3 (Table 1).

In these experiments the effect of various T-independent anti-

gens on mouse C3 was examined, as their immunogenic and mitogenic properties have been previously tested in this species. Earlier observations that LPS and some other polysaccharides activate C3 by the 'bypass' mechanism in various species 18-20 are confirmed.

Regarding the significance of C3 activation for T-cell independent B cell triggering however, two points may be made. First, the capacity of an antigen to activate C3 does not necessarily make it T independent. For example, Klaus and Cross<sup>3</sup> have shown that DNP<sub>50</sub>BSA elicits a T-cell dependent IgM response; yet DNP<sub>50</sub>BSA activates C3 effectively (Table 1). Furthermore, the C3 activating CoF itself, which readily elicits antibody in intact mice (and for that reason normally becomes ineffective within 4-5 d) has a prolonged action and fails to elicit detectable antibody in thymus deprived mice (J.P. and J.H.H., unpublished).

Second, the capacity to activate C3 by the 'bypass' mechanism, at least as measured by cleavage of C3 in vitro, does not seem to be an obligatory feature of T-independent immunogenicity (Table 1). Nevertheless our preparation of DNP-lyslevan, which activates C3, is considerably more immunogenic in C3H mice than DNP-lys-SIII, which does not. Similarly, native LPS is a more potent immunogen than LPS treated with acidor alkali (G.G.B.K., unpublished). (In the latter case, however, the comparison is complicated by the fact that native LPS is a potent polyclonal mitogen.)

It seems that neither activation of fluid phase C3 nor 'nonspecific' (mitogenic) activation<sup>17</sup> can be essential prerequisites for specific B cell triggering. The capacity of an antigen to activate fluid phase C3 and/or to cause polyclonal B-cell proliferation, however, may well enhance its intrinsic immunogenicity. Furthermore, it is possible that T-independent antigens which do not activate fluid phase C3 may nevertheless do so, when bound at a cell surface. This possibility is being investigated.

## Differential recognition by thymocytes of H-2 and non-H-2 alloantigens

In this report we examine the behaviour of mouse thymocytes in the mixed lymphocyte culture. The thymus is believed to contain large numbers of T cell precursors or immature T cells undergoing differentiation before migrating to the peripheral lymphoid areas as mature, immunocompetent cells. Our results suggest that the thymus contains a class of cell possessing the potential to react against products of H-2 and non-H-2 loci, but that mixed leukocyte culture reactivity against H-2 depends on a factor(s) present in normal mouse serum.

Thymus-dependent (T) lymphocytes have long been suspected of playing a major role in cytotoxic reactions against cell-associated alloantigens<sup>1-5</sup>. T-cell mediated cytotoxicity is usually dissociated into two phases: a recognition phase, resulting in clonal proliferation of antigen-activated cells, and a destructive phase, in which activated cells within the responding population demonstrate cytolytic activity against cells bearing the sensitising antigens<sup>6-9</sup>. These proliferative and effector phases have been studied *in vitro* using the mixed leukocyte culture (MLC) and cell-mediated lympholysis (CML) assays, respectively. For most species MLC activation as well as cell destruction are associated with loci of the major histocompatibility complex (MHC). In the mouse, however, MLC activation can be induced by genetic differences at loci segregating independently of the MHC (H-2)<sup>10,11</sup>.

Lymphocyte activation was examined in the sensitive miniaturised mouse MLC assay<sup>12</sup> using serum-free<sup>13</sup> and mouse

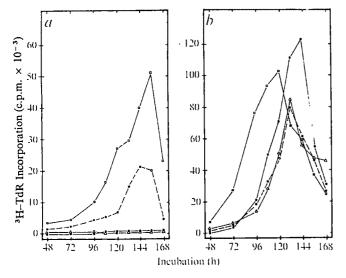

Fig. 1 MLC activation of thymocytes by H-2 and non-H-2 alloantigens in serum-free and mouse serum supplemented media. C57BL/10 thymocytes were mixed with X-irradiated B10.A (△), B10.D2 (●), A/Jax (○) or DBA/2 (□) spleen cells in serum-free (a) or mouse serum supplemented (b) media. 2.0 μCi ³H-TdR were added to each culture 8 h before termination of MLC at the times indicated.

serum supplemented<sup>14</sup> culture media. The genetics of mouse strains used in this study have been described elsewhere<sup>15–18</sup>.

MLC responsiveness of thymocytes from 3-5-week-old mice against H-2 and non-H-2 alloantigens was determined in serumfree and mouse serum supplemented media. Figure 1 shows thymidine (3H-TdR) incorporation for C57BL/10 (H-2b) thymocytes stimulated with X-irradiated spleen cells from (1) B10.A (H-2a) or B10.D2 (H-2d), • two strains possessing genetic differences with C57BL/10 at H-2, and (2) A/Jax (H-2<sup>a</sup>) or DBA/2 (H-2d), two strains differing from C57BL/10 at both H-2 and non-H-2 loci. C57BL/10 thymocytes showed no MLC reactivity against either B10.A or B10.D2 spleen cells in the absence of mouse serum; however, in the presence of serum strong MLC activation occurred. In contrast, C57BL/10 thymocytes responded against A/Jax and DBA/2 spleen cells in both culture media. Similar response patterns have been obtained using numerous strain combinations. Reactions of B10.BR thymocytes mixed with X-irradiated spleen cells from strains with various genetic differences are shown in Table 1. That non-H-2 differences alone are sufficient to induce MLC activation in serum-free medium is demonstrated by the B10.BR-C58 combination.

This differential reactivity of murine leukocytes responding against H-2 and non-H-2 alloantigens in serum-free and mouse serum supplemented media can be demonstrated with thymocytes from 3-5-week-old mice, but is not demonstrable with cells from peripheral blood, lymph node, spleen, or thymus of cortisone-treated mice. These tissues contain few immature cells and are reactive against H-2 alloantigens in either serum-free or serum supplemented medium.

Recent reports 19,20 have shown that various agents—thymus extracts or cyclic AMP—cause differentiation of presumably immature thymocytes into functionally mature T cells. A similar mechanism might also be responsible for the serum requirement in thymocyte responses against H-2 alloantigens. One approach in the examination of this point was to use serum from homozygous nude mice which are athymic and therefore should be deficient in thymus hormone(s). The activity of serum from nude mice (possessing the homozygous nu locus on a BALB/c background) was compared with serum from normal BALB/c mice (Fig. 2). B10.D2 spleen cells or thymocytes were mixed with X-irradiated spleen cells from DBA/2, a strain possessing only non-H-2 differences, or C57BL/10, a strain possessing an H-2 difference, in media supplemented with serum from either normal or homozygous nude mice. The results indicate that B10.D2 thymocytes (Fig. 2a) respond much more strongly against C57BL/10 spleen cells (an H-2 difference) in medium supplemented with serum from normal BALB/c mice than in medium supplemented with serum from nude mice. In contrast, thymocyte responses against the non-H-2 antigens (DBA/2) showed no marked difference in the ability of the two sera to support the mixed reactions. There was little or no difference between the 3H-TdR incorporation by spleen cells responding against H-2 or non-H-2 alloantigens in the two sera (Fig. 2b). These results parallel the serum requirement for MLC activation of thymocytes with H-2 but not non-H-2 alloantigens shown in Figure 1 and Table 1. Note, however,

Table 1	MLC responses of normal thymocytes against H-2 and non-H-2 alloantigens

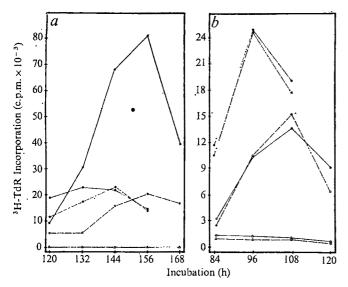

Fig. 2 MLC activation of thymocytes and spleen cells by H-2 and non-H-2 alloantigens in medium supplemented with serum from normal or nude mice. B10.D2 thymocytes (a) or spleen cells (b) were stimulated with X-irradiated C57BL/10 (c) or DBA/2 ( ) spleen cells in medium supplemented with serum from normal (—) or nude (- - -) mice. 2.0 µCi ³H-TdR were added to each culture 8 h before termination of MLC at the times indicated.

that some reactivity occurs using the serum from nude mice in the reaction of B10.D2 thymocytes against C57BL/10 cells.

Results of this study suggest the presence in mouse serum of a factor (or factors) which confers a state of immunocompetence on a class of cell which resides in the thymus of young mice and which is highly reactive against the products of H-2. The serum component permitting mouse thymocytes to respond against H-2 alloantigens is the subject of much speculation, as is the mode of action. Results of experiments showing the effects of serum from normal and from homozygous nude mice on the thymocyte responses to H-2 and non-H-2 antigens strongly supports the concept that this is a 'thymus factor'.

At present, it seems most probable that mouse serum acts on the T-cell precursors or immature T cells of the thymus and induces the state of immunocompetence (for example, development of specific receptor sites on the surface of the T cell). This possibility is supported by studies<sup>20</sup> in which a serum factor secreted by humans and mouse thymus confers on immature cell populations rosette forming capacity or a state of responsiveness to concanavalin A (con A).

In addition to H-2 reactive cells, the thymus also contains a class of cell reactive against products of the non-H-2 loci. On the basis of their MLC responsiveness in the serum-free medium these are probably a different class of cell. It is unlikely that responses against non-H-2 alloantigens in serum-free medium are due to their being more immunogenic than the H-2 alloantigens, because in the serum supplemented medium responses to H-2 are usually stronger than to non-H-2 antigens (Fig. 1).

H-2 alloantigens represent a special class of antigens to the immune system—they serve as highly effective target antigens for T-cell mediated cytotoxicity whereas non-H-2 antigens do not<sup>8</sup>. Other studies (A. B. Peck, unpublished data) show that thymocytes develop cytotoxic potential after their strong MLC activation by H-2 alloantigens only in the presence of mouse serum; no CML is observed in serum-free medium. Thymocytes also fail to develop cytotoxic potential against non-H-2 alloantigens despite strong MLC activation in strain combinations possessing genetic differences at only non-H-2 loci in either medium.

This culture system may define two classes of T cells by their in vitro response patterns to H-2 and non-H-2 antigens, and provides an easy method for identifying T cell functions of the two classes. Studies are in progress to separate and isolate the two cell types.

#### **Erratum**

In the article "Science and works of art" by J. P. Brommelle and N. S. Brommelle (Nature, 250, 767; 1974) the address given for N. S. Brommelle was incorrect. N. S. Brommelle is at the Victoria and Albert Museum.

#### Corrigendum

In the article "Radiological mapping of the ribosomal RNA transcription unit in E. coli" by P. B. Hackett and W. Sauerbier (Nature, 251, 639; 1974) the authors erroneously referred to the work of Bleyman et al. (J. Bact., 99, 535; 1969) (ref. 20) as being conducted in E. coli. These studies of Bleyman et al. utilised B. subtilis in which the transcriptional order of the ribosomal RNA genes seems to be the same as in E. coli (Pace, N. R., Bact. Rev., 37, 562; 1973) (ref. 1).

# matters arising

### Immunopathy of parasitic infection

THE News and Views article 'Immuno-pathology of Parasitic Infection" by our correspondent F. E. G. C. (246, 187; 1973) has elicited several letters. He wrote "most parasites are capable of evoking immune responses in their hosts but these are seldom effective in eliminating the infection" and in conclusion that "as more information about immunity to parasitic diseases accumulates the possibilities of developing useful methods of immunisation fade further and further into the distance".

• Professor G. M. Urquhart of the University of Glasgow writes: "The first statement is inaccurate and the second is surely a personal opinion largely based on an erroneous extrapolation of the excellent work of Warren¹ who has shown that schistosome egg granulomata are the product of a delayed-type hypersensitivity reaction.

The development of a highly effective degree of acquired immunity both in the sense of the elimination of infection and in resistance to reinfection has been shown to occur in many experimental helminth infections and in domestic animals its natural acquisition plays an essential role in the survival and health of adult cattle, sheep and horses constantly exposed to heavy infection. Over the past 16 yr millions of calves in Europe have been successfully immunised with a vaccine prepared from X-irradiated larvae against Dictyocaulus viviparus, the lungworm of cattle.

The same situation applies to protozoal infections. Antigenic variation does present a problem in artificial immunisation but under natural conditions man and animals survive in large numbers in malarial and trypanosome endemic areas respectively, apparently through the development of an effective immunity. Leishmaniasis in experimental animals and man and coccidiosis in domestic animals also offer excellent examples in which acquired immunity is highly important in protection.

For many years immunological research on many of these important diseases was neglected and we should not be too dismayed if the present in-

terest in parasitic immunology elicits some facts which, at least at first sight, appear disheartening from the viewpoint of the rapid development of a comprehensive range of vaccines."

• Dr D. G. Colley of Vanderbilt University, Tennessee writes: "The final paragraph draws a conclusion regarding immunisation potentials in parasitic infections which, although possibly correct, is based on what I consider to be erroneous reasoning. It reflects a misinterpretation of the basic tenets of either parasitology or immunology, or both. I do not argue with the possibility that the induction of a protective immune response in schistosomiasis may be difficult, or even impossible to achieve. As has recently been pointed out such immune resistance mechanisms have certainly not been convincingly demonstrated and may not even exist.

The article seems, however, to base this assumption upon the demonstrated immunopathogenic effects of an antiegg response. This ignores both the uniqueness of the various intramammalian stages of the schistosomes (schistosomules, adult worms, eggs) and the fundamental concept of immunological specificity. Certainly to induce or increase anti-egg cell-mediated responses could be potentially disastrous (although the induction of enhancing antibodies might be beneficial). Responses against egg antigens have, however, long been seen as of little protective consequence. What the discipline needs, and many investigators are pursuing, is more attention to immune responses against specific antigens."

◆ Dr T. A. Miller, of the Jensen-Salsbery Laboratories, Kansas City, Missouri, writes: "The article should more appropriately have been entitled "Immunopathology of Schistosomiasis". The emphasis on this one host-parasite relationship excludes, for all practical purposes, consideration of the other 95% of parasitic infection. Moreovar, the final statement represents only one aspect of the current international opinion, viz-à-viz schistosomiasis.

As a general statement applicable to the other 95% of parasitic infections, this is patently uninformed and misleading in view of the proven efficacy, safety and widespread use on two continents of irradiated nematode vaccines for lungworm disease of cattle and sheep and hookworm disease of the dog."

### Population estimates from recapture studies

Bell suggested that P = ((N-a)!(N-n)!)/(N-n)!(N! (N-a-n)!) is the probability that a population is not larger than N in size, where a animals have been captured, marked, and released, and on a subsequent occasion n animals have been captured, all of which have been found to be unmarked. Though P is indeed the probability of the latter event given that the size of the population is N, Bell advances no reason why the probability that the population is not larger than Nshould be equated to it. Indeed, Fisher<sup>2</sup> has stressed it should not: 'The direct step from the test of significance to a probability distribution cannot be sustained, and this circumstance has been responsible for some misunderstanding, and confusion of the terminology.'

Were Bell's treatment valid we could find the probability that the population is of size N exactly by subtraction, yielding

 $p = an \times ((N-1-a)!(N-1-n)!)/(N! (N-a-n)!)$ 

Suppose one marked animal were released (a=1) and subsequently one animal captured and found to be unmarked (n=1). Then p=1/N(N-1), indicating, for example, that N=10 is 110 times more probable than N=100. But most people, I suggest, would feel that they had learnt very little about N (except that it was at least 2), and they would be almost indifferent between N=10 and N=100.

This is reflected in the solution given by likelihood theory<sup>3</sup>, in the context of which the problem is entirely standard. Since P is the probability of what was observed, given N, it is the likelihood of the hypothesis N given what was observed. It attaches a likelihood to each possible value of N, increasing from n!a!/(n+a)! for N = a+n, to unity for N very large. For the case a = n = 1, P = (N-1)/N, indicating that 100 is only 1.1 times more likely than 10.

A minimum estimate of population size is given by the lower 2-unit support limit<sup>3</sup> found by solving  $P=1/e^2=0.1353$  for N. By the very nature of the problem there can be no upper limit, and likelihood theory prescribes none.

A. W. F. EDWARDS

Gonville and Caius College, Cambridge, UK

 Bell, G., Nature, 248, 616 (1974).
 Fisher, R. A., Statistical Methods and Scientific Aprence (Oliver and Boyd, Ediabatical 1056).

Edinburgh, 1956).

Bedwards, A. W. F., *Likelihood* (Cambridge University Press, 1972).

DR BELL REPLIES—Edwards makes two major points: first, that my estimate¹ of population size is strictly invalid; and secondly, that it is of no practical value in situations where its use might be considered.

Although no statistician, I have satisfied myself that Edwards' first point is correct, and that the closing sentences of my original communication must be revised. If no recaptures are made, then clearly P = 1 when the population is assumed to be infinitely large. This does not mean that it is absolutely certain that the population is infinitely large; on the contrary, we may be quite sure that it is not. It means that if the population were infinitely large, we could be quite certain that no recaptures would be made. At some finite value of N, say  $N^*$ , the value of P will be 0.5; that is, if we performed many recapture surveys, obtaining the same sample size on each occasion, we would fail to make any recaptures on about half the total number of occasions. If, therefore, we perform a recapture survey and obtain no recaptures, we still have no evidence that the population is really larger than N\*; and it is in this sense that  $N^*$  is a minimum estimate of  $\dot{N}$ . The value of P chosen depends on how certain we wish to be in setting an upper limit to N\*.

Edwards' second point seems less fully justifiable. The example that he gives involves the very smallest sample that can yield any information\_whatsoever concerning the size of the population, and it is not surprising that only the most tentative conclusions can be formed. With larger samples, useful information can be obtained which is not utilised by standard recapture techniques: in a study of the distribution of population size in newts (G.B., unpublished), the results obtained from the nil-recapture method were found to be entirely consistent with those obtained from two other techniques; stochastic and deterministic recapture surveys, and trap-ratio estimates (Fig. 1). Statistical analysis is primarily a means of interpreting observations of nature, rather than an independent academic discipline. and it is to be hoped that the nil-recapture

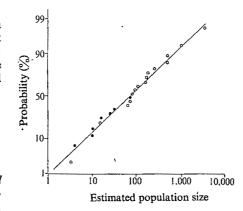

Fig. 1 The distribution of population size in the smooth newt (Triturus vulgaris (Linn)) near Oxford (G.B. unpublished). Each point represents the estimate of the size of a single population. The data are plotted according to the method of Harding<sup>2</sup> for small samples; population size can be seen to be lognormally distributed.  $\bullet$ , Estimates due to the nil-recapture method, using P=0.5;  $\bigcirc$ , estimates from standard recapture techniques, or from a known relationship between the rate of trap-captures and the total population size.

method will be useful, in some circumstances, to biologists working in the field. It may be that its rationale is less rigorous than that of the higher reaches of likelihood theory, but it is at least comprehensible to field biologists without specialised mathematical training. To accept mathematical conclusions whose truth one is unable to establish personally, is to accept the argument from authority—against which all scientific enquiry is a revolt.

# Protein phosphorylation during oocyte maturation

Morrill and Murphy<sup>1</sup> suggested that "the release of prophase block at ovulation is associated with intense protein phosphorylation" coinciding with 'the activation of a protein kinase (possibly via cyclic AMP)". They further found that "the principal protein species phosphorylated between meiotic prophase and the second metaphase appears to be the phosphoprotein phosvitin". But proper controls for their experiments seem to have been missing. It was not determined whether oocytes that remained in prophase block but were exposed to the same amount of  ${}^{32}P_{1}$  for the same time as those undergoing maturation would also have phosphorylated endogenous protein, as our experience indicates2.3. Nor is it clear that their phosvitin was authentic.

We have repeated their experiments, using an in vitro system. Approximately

120 fully grown oocytes from Xenopus laevis (injected with 1,000 U of human chorionic gonadotrophin 3 weeks preously to flush out over-ripe oocytes) vere dissected manually from their follicles and placed for 2 h in 10 ml of solution O-R2 (ref. 4) containing 1 mCi <sup>32</sup>P<sub>1</sub> (carrier-free, Schwarz/Mann). After 2 h they were washed, and half were placed in 15 ml of solution O-R2 containing 10 µg progesterone ml<sup>-1</sup> to induce maturation<sup>5</sup>. Remaining oocytes were placed in progesterone-free medium (zero time). After 30 min both groups were transferred to medium lacking progesterone. At 6 h, approximately 60% of progesterone-treated oocytes had a diffuse white area centred at the animal pole, indicative of germinal vesicle breakdown5. By 9 h, virtually all treated oocytes had the white area, while untreated oocytes were negative. Dissection of boiled oocytes indicated that the appearance of a white area corresponded with the vesicle breakdown in every case examined (N = 24). Sterile technique was used, 10 µl of antibiotic-antimycotic solution (Grand Island Biological Co.) was added per ml of incubation medium, and the temperature was 20° C.

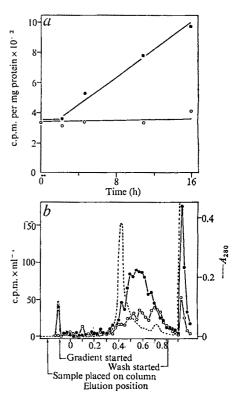

Fig. 1 a, Specific activity of <sup>32</sup>P-protein in progesterone-treated oocytes (●) undergoing maturation and control oocytes (○). Oocytes were preincubated for 2 h before zero time in <sup>32</sup>Pi. Each point represents the average of three determinations. The arrow indicates the time of progesterone treatment. b, DEAE-cellulose chromatography of extracts from oocytes taken at the end of the 16-h period indicated in (a). The dashed line is the absorbance trace; other symbols are as above.

At various times oocytes were placed in water at 100° C. After several minutes, each was transferred to 0.5 ml of 1% sodium dodecyl sulphate plus 5 mM dithiothreitol (pH 8.0) and incubated at 50° C until dissolved. Samples of dissolved oocytes were placed on 23-mm diameter disks of Whatman No. 42 paper, air-dried and treated with cold and hot trichloroacetic acid (containing 1 mM NaH<sub>2</sub>PO<sub>2</sub>) and alcohol and ether to remove low-molecular-weight material, nucleic acid and lipid2. The disks were counted for 32P-protein in a Beckman Lobeta II planchet counter and then used to determine total protein<sup>6</sup>. Figure 1a shows that, after a lag of several hours, the specific activity of the progesteronetreated oocytes increased with time, whereas that of the untreated oocytes did not.

After 16 h, 45 oocytes from each group were homogenised in strong salt solution2, dialysed and chromatographed on a 23/0.9 cm TEAE-cellulose column7. Under these conditions lipovitellin and phosvitin eluted at positions 0.42 and 0.72, respectively. Samples from each fraction were assayed for 32P-protein3 (Fig. 1b). Neither lipovitellin nor phosvitin appeared to be specifically labelled in either case, and the increased amount of labelled material in progesteronetreated oocytes was found (a) initially percolating through the column, (b) between the lipovitellin and phosvitin peaks, and (c) eluting with the wash solution at the end of the run.

We conclude that there is an increase (although not intense) in protein phosphorylation during oocyte maturation, but that phosvitin is not involved. Phosvitin could serve as an energy source during embryogenesis, as suggested1,8. The dephosphorylation observed by Morrill and Murphy during early embryogenesis, however, probably involves some other protein(s). We do not yet know whether the increased phosphorylation during oocyte maturation results from an "activation of a protein kinase (possibly via cyclic AMP)." We have previously described a protein kinase from amphibian oocytes and eggs that is stimulated by cyclic AMP when histone is used as the substrate but not when phosvitin is the substrate<sup>8</sup>.

This research was sponsored by the US Atomic Energy Commission under contract with the Union Carbide Corporation.

Dr Morrill replies—Dr Wallace appears to confirm our observation1 that release of the prophase block in amphibian eggs is associated with increased protein phosphorylation. The in vitro studies of Wallace and our in vivo studies are not, however, directly comparable. We injected <sup>32</sup>Pi directly into gravid females together with inducing levels of pituitary extract. It is our experience that isolated body cavity (ovulated) eggs take up and incorporate <sup>32</sup>Pi and would probably do so in both the body cavity and oviduct. The in vivo maturing eggs were thus exposed to 32Pi for at least 24 h until released from the oviduct. In contrast, Wallace preincubated isolated oocytes with 32Pi for 2 h and then transferred the oocytes to medium containing progesterone and unlabelled Pi. We have found that intracellular 32Pi of excised oocytes exchanges rapidly with extracellular Pi. Thus, during the progesterone stimulus 32P incorporation into protein would be limited to diminishing endogeneous supplies of phosphorylated nucleotide. This might contribute to the lower overall protein phosphorylation reported in the in vitro system, and possibly to differences in the protein species phosphorylated.

The main difference between our results and those of Wallace is the identification of the phosphorylated protein species. A comparison of a number of phosvitin extraction methods indicated that the major 32P-labelled protein(s) of the in vivo ovulated frog egg could be isolated by the method of Mano and Lipmann<sup>2</sup>. This ovulated egg 'phosvitin' co-electrophoresed with commercial hen's (ovulated, unfertilised) egg phosvitin on SDS polyacryalamide gels. This 'phosvitin' differs from that characterised by Wallace3 in that: (1) it has a lower phosphate content; (2) it is extractable with lower salt concentrations; and (3) it is associated with the cortical pigment granule fraction and not with the yolk platelets. This suggests that amphibian egg phosvitin exists more than one metabolically active form, one principal difference being the level of phosphorylation. In this regard, Mano and Lipmann<sup>2</sup> have shown that fish egg phosvitin can be separated into discrete peaks containing 3.2, 5.7, 7.2, and 9.5 % P. The existence of discrete phosphorylation levels of the same protein backbone structure is particularly interesting.

Neither our maturing oocytes nor Wallace's were compared with the ideal control, that is oocytes completely free of follicle cells. In contrast to the ovulated eggs used in our experiments, oocytes dissected manually as described by Wallace retain a surface layer of intact follicle cells and these cells may also actively phosphorylate protein. When we injected 32Pi into gravid females with no hormone stimulation we recovered 32Plabelled protein in excised ovaries and manually dissected oocytes after 24-48 h in vivo. But, there was no significant 32P incorporation into the 'phosvitin' fraction isolated as described above. This latter information was accidentally omitted from our final reduced manuscript, through the oversight of the authors.

#### Tin mineralisation

SILLITOE's recent letter1 on tin mineralisation and mantle hotspots is grossly misinformed about the age of the tin mineralisation in South West Africa. The tin deposits do occur in pegmatites but they are unrelated to the possible plume generated Jurassic-Cretaceous alkaline complexes in Damaraland. Instead the pegmatites are related to the Late Precambrian Damara orogen. Radiometric age determinations for a number of pegmatites are in the range 450 to 650 Myr (ref. 2.) I know of no tin mineralisation associated with the Mesozoic alkaline granites in South West Africa and they cannot, therefore, be used to support the contention of a relationship between tinbearing silicic rocks and mantle hot spots.

### Primary structure of E. coli dihydrofolate reductase

In a recent paper, the primary structure of Escherichia coli dihydrofolate reductase was reported from this laboratory. The paper also suggested a

similarity between a portion of its primary structure and a portion of four vertebrate dehydrogenases.

In a private communication, Drs M. Rossmann and C. Brändén have informed us that the portions of three of the four dehydrogenases chosen for comparison are not from comparable areas of their tertiary structure2-6, and that the statistical treatment given in my paper is inappropriate.

The misalignment of the dehydrogenases does not, of course, affect the primary structure of dihydrofolate reductase shown in Fig. 1 of ref. 1.

#### All female butterfly broods

Owen, Owen and Chanter<sup>1</sup> have invoked Y-linked meiotic drive to explain the high frequency occurrence of allfemale broods in some populations of the African butterfly Acraea encedon. This mechanism does not account for the following observations<sup>2</sup> of these populations: first, that they only occur in 'disturbed' areas; second, that females aggregate and lay egg batches in close proximity to each other; and third, that females 'court' other females.

The following explanations are advanced for these observations. First, an environmental disturbance (with its consequent effect upon larval food plants) will alter the spatial relationship between egg batches. In mixed sex progeny this may well increase the probability of the first matings being between brother and sister. All-female

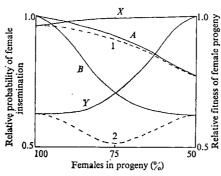

Fig. 1 Net female fitness values (curves 1 and 2) of broods varying in their sex ratio. Curves A and B show a reduction in fitness of females from mixed broods relative to that of all-female broods (as a result of in-breeding). Curves X and Y show the consequent reduction of female insemination probability in all-female broods relative to mixed broods. Net female fitness values calculated by multiplying relative probability of insemination of female progeny by relative fitness of female progeny (curve  $1 = A \times X$ , curve  $2 = B \times Y$ ).

broods do not sustain this disadvantage. Such inbreeding will increase the homozygosity of the genetic environment surrounding the normal Y chromosome and viability loss is a well documented aspect of homozygosity3-5. Therefore the mutant chromosome will sustain an advantage and spread through the population. As it does so, the probability of all-female broods being laid near mixed broods increases and with it the inbreeding probability of these latter broods.

As male frequency drops, however, mixed brood females have a greater probability of insemination<sup>1</sup>. The figure shows that with increased inbreeding the net fitness of all-female broods increases (curve 1) and then reaches equality (curve 2) with respect to mixed broods as male frequency drops.

Second, a mutant female laying its eggs in close proximity to a mixed sex batch will increase the insemination probability of its offspring. The aggregation and egg laying strategies may therefore be accounted for.

Third, any mutant female able to predict oviposition in another female and act as in the second case above will sustain an advantage. This, I suggest, may account for intra female 'courting'.

In non-disturbed (and possibly some disturbed) areas the Y mutant must sustain a net selective disadvantage as evidenced by its non-appearance. The •nature of this selective pressure is not yet known.

(1950).

DR CHANTER REPLIES—Over the years, we have received many suggestions as to how the curious population biology of Acraea encedon might be explained, and we welcome another. There are, however, some difficulties with Manning's explanation of the tendency for the occurrence of all-female broods to be associated with 'disturbed' areas. Here I will confine myself to two of these difficulties, both concerned with the figure.

First, the lines on the graph are quite arbitrary, and the different slopes of curves 1 and 2 result from the fact that while curves Y and B have been drawn as reflections of one another (about a vertical line through the 75% point), X and A have been drawn asymmetrically. It would be easy to alter the asymmetry of curves X and A and reach a different conclusion.

Second, to obtain the net fitness of all-female broods relative to that of females from mixed broods (curves 1 and 2), it is necessary to multiply curves X and Y by the reciprocals of curves A and B rather than by curves A and B as they stand, since the relativity in curves A and B is opposite to that in X and Y.

Manning's explanation of the aggregating behaviour is interesting, but would be more convincing if the eggs laid by participating females were fertile-all the eggs we have collected from aggregations have been infertile1.

Finally, I must emphasise that we have not established conclusively that the sex ratio trait is caused by a Ylinked gene, and that we also have some idea as to why the trait is not established in some populations, as explained in our paper2 in which the peculiarities of an isolated population at Gegbwema in Sierra Leone are described. More recently we have discovered a population at Dar es Salaam in which the trait may be just beginning to appear and we hope that this discovery may yield additional information.

John Gribbin & Stephen Plagemann

Earthquakes are the most devastating natural phenomenon known to man and have taken an enormous toll of life and property throughout human history. Until now, we have had no accurate means of predicting their occurrence although much effort has been put into research to discover the possible mechanisms which trigger off these cataclysmic events. John Gribbin and Stephen Plagemann present in this book a new model which aims at predicting earthquakes through the study of the hitherto unrecognized and apparently unrelated phenomena of planetary alignments, sun spot activity and the solar wind, and their vital role in determining the course of natural events on earth. These causal links are shown to affect earth movements in active seismic areas and thus unleash the powerful forces which cause earthquakes. Earthquakes are the most devastating natural phenomenon

But their research goes beyond the general model. A particularly unusual planetary alignment will occur within the next ten years and the authors argue a convincing scientific case for major earthquake activity during that period and stipulate the year in question. In particular they show that an earthquake of devastating proportions may well occur along the highly active seismic zone of the San Andreas Fault in California which runs through the cities of Los Angeles and San Francisco. The physical, social and economic implications of a major earthquake in this populous area are far reaching. They make this a book which should be read by all scientists and non-scientists concerned about the effects of natural events beyond the immediate control of man.

# Orbital Theories of Molecules and Solids

Edited by N. H. March

This book is dedicated to Professor C. A. Coulson who made outstanding contributions to the method of molecular orbitals. It provides a co-ordinated set of authoritative reviews for graduate students both in theoretical chemistry and theoretical physics. The coverage is of band theory of perfect crystals, defect solids, electronic structure of molecules, intermolecular forces, and molecular crystals. £10.75

# Problems in Physical Chemistry

Alexander Wood

This carefully chosen collection of physico-chemical exercises is intended primarily for first- and second-year degree course students in chemistry and applied chemistry, and for those taking the H.N.C., H.N.D., and Part I of the Grad. R.I.C., but the inclusion of a few more difficult problems should also make it useful for more advanced students. SI units are used throughout. Paper covers £1-95

### Modern Physical Techniques in Materials Technology

Edited by T. Mulvey and R. K. Webster

Practically the whole range of modern physical methods for the analysis of materials is encompassed in this volume. The basic principles of each technique are explained, the essential form of the apparatus needed is described, and sufficient guidance is given for the inquiring reader to evaluate each technique and pursue it further for himself. The book will also be found useful by specialists for the overview it gives of the subject as a whole. £9.50 Harwell Series

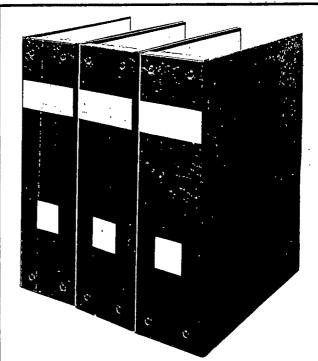

### Bibliography of Ab Initio Molecular Wave Functions

Supplement for 1970-1973

W. G. Richards, T. E. H. Walker, L. Farnell, and P. R. Scott

This Supplement to the standard work of reference has been produced as a result of requests from users, and continues the chronological survey from 1 January 1970 to 31 December 1973. More work was published in this period than in the whole previous history of the subject. The Supplement follows the pattern of the earlier compilation: each molecule or ion is treated separately, tables quote the nature of the basis set and the calculated energy value. It should prove invaluable to theoretical chemists and experimentalists alike. Paper covers £9.50 Oxford Science Research Papers

# reviews

THE publication of this book comes at an opportune time in the development of potentially important applications of superconductivity; a time when important decisions on the extension of existing programmes are under consideration.

Unlike the semiconductors, the future of superconductors seems to be in their application to large scale engineering devices such as high field magnets in particle accelerators, power cables, large machines and generators, and magnetic levitation and linear motor propulsion systems. The basic thinking behind nearly all of these schemes is that they apparently offer the best solutions to many of the economical and social problems facing the advanced countries of the west in such fields as the energy crisis, dwindling natural resources, and pollution and the environment.

Based on discussions that took place in a select NATO gathering of some of the world's leading experts in the fields of superconductivity and low temperature engineering, this book has been biased towards the large scale engineering projects rather than the purely scientific interests. The original conception and subsequent planning of the NATO Institute, which culminated in this publication, resulted almost entirely from the efforts of Simon Foner and Brian Sohwartz of the Francis Bitter National Magnet Laboratory at MIT, who must be warmly congratulated.

Although the phenomenon of superconductivity was discovered by Kamerlingh Onnes as long ago as 1911, until recently it has been extremely slow in making its mark in the real world of practical technology. Only since our understanding of superconducting behaviour and the metallurgy of the type II materials has been established in the last decade or so has the successful manufacture of superconductors been possible. But although operation at liquid helium temperatures has become an engineering routine the real problem still remains, namely, that of introducing the conventional engineer to a new low-temperature environment and convincing him of the reliability and safety of cryogenic devices. This situation has been further aggravated by the huge development costs which inevitably are involved in all such large scale applications. The timely appearance of this book presents the situation

# Towards a new technology

R. G. Rhodes

Superconducting Machines and Devices: Large Systems Applications. Edited by Simon Foner, and B. B. Schwartz. Pp. xx+692. (NATO Advanced Study Institutes Series.) (Plenum: New York and London; NATO Scientific Affairs Division, 1974.) \$47.00.

in exacting detail as it existed in seven different countries up to the end of 1973. It is divided into 17 chapters extending to some 690 pages, contributed by nearly two dozen authors.

The first seven chapters constitute by far the major contribution. Each treats in considerable detail a specific area of technology in which superconductivity is the essential part. The more significant fields of investigation are introduced in the first chapter by J. Powell of the Brookkaven National Laboratory. In particular, he makes a special case for the magnetic levitation of high speed ground transportation systems using the so-called null flux system, an area of applied superconductivity in which he has a special interest. The theory and fabrication of practical superconducting materials are discussed in detail in chapter 2. On the basis of our present metallurgical understanding and experimental research a Tc of 25 K could be realised by 1985. That would truly be a significant breakthrough for cryogenics.

The one important application in which superconductivity has found a permanent niche is that of high field magnets and, more particularly, in the field of high energy physics. The design, construction and behaviour of the more significant magnet systems in the various major laboratories throughout the world are discussed in chapter 3. The following two chapters are devoted to rotating machines. The design details of a superconducting homopolar motor, and its successful application at the Fawley power station, is described. From the results of further experimental projects on d.c. machines it is predicted that the heavy industrial power industry is poised on the threshold of a new era.

Considerable progress has also been made on parallel programmes investi-

gating the application of superconducting windings to a.c. machines, which are discussed at length in chapter 5. The preliminary design calculations indicate that the current density available with high field superconductors may well provide an increase in the economic power density by a factor of 5 to 10 over conventional machines, and may also have a significant volume advantage.

The case made in the first chapter for a mass ground transportation system using superconducting magnets is taken up again in chapter 6, with arguments for an alternative repulsion system and linear synchronous motor propulsion. From exhaustive theoretical studies confirmed by laboratory tests there seem to be no fundamental technical problems which remain to be solved. There are, however, many technical innovations needed before such a high speed transportation system can be put into practical use.

One of the first applications to be seriously examined was the superconducting power cable. With the constantly increasing demand for electrical power, generating stations of ever increasing size are required and, therefore, so are transmission systems of higher capacity and efficiency. The construction and configuration of both a.c. and d.c. cables are fully described in chapter 7. The 12 major superconducting cable projects being undertaken at 10 different laboratories throughout the world are considered to be fully justified by the fact that they represent the most economical solution for power ratings of 2,000 MW or more, which are expected to be the norm in the not too distant future.

Chapters 8, 9 and 10 are supplementary chapters in which three promising areas in the new technology are discussed. The use of hydrogen as an energy carrier is described in chapter 8, followed in chapter 9 by an account of the Josephson junction as a computer device. In chapter 10 a project investigating the use of superconducting magnets for high grade magnetic separation is outlined.

Finally, in seven relatively short chapters from 11 to 17, the essential details of the national programmes in applied superconductivity being undertaken in France, Germany, Italy, Japan, Switzerland, the UK and the US are outlined and details of the institutions, the personnel, and funding

have been included. That innovation in a book of this nature is a welcome addition and, as pointed out in the preface, should lead to better national planning as well as to international cooperation.

This is a book of international status in every sense and there seems little doubt that it should go a long way in promoting a better and wider understanding of this important area of low temperature technology. It should prove to be an invaluable aid to the decision makers in the assessment of future large scale technologies.

# Starting with an open mind

Development in Infancy. (A series of Books in Psychology.) By T. G. R. Bower. Pp. viii+258. (W. H. Freeman: San Francisco and Reading, July 1974.) £5.20 cloth; £2.90 paper.

It was the style of 18th Century philosophers of mind to premise their arguments upon speculative assumptions concerning the original nature and subsequent development of human perception. Bower's splendid little book is in that tradition—but with one hugely crucial difference. In place of speculative assumptions about the original nature of perception the pages of this volume provide a stunning array of experimental research, much of it by the author and his collaborators, designed to explicate how in fact the infant during the opening years of life comes to perceive space, objects, locus and trajectory, and how he develops appropriate concepts and behaviours to cope with what he comes to know. Bower has given us not only a compendium of empirical findings, but a speculatively (sometimes too speculatively) argued treatise on the starting nature of human knowledge and the course of its early transformation in response to encounters with the environment.

It may well be the most important work on early human development since the launching of Piaget's magisterial research a quarter of a century ago, and although it brings that work into question both broadly and in detail, it builds upon it as a starting point. For it is not the work of the Geneva group that is brought most deeply into doubt by this book, but rather the empiricist view of knowledge-the assertion that knowledge is acquired by the gradual accretion of associations or stimulus-response connections that mirror the state of the environment. Indeed, Bower's conclusions point instead to the early importance of man's inherent structure, to the array of

species-typical readinesses to register upon and organise knowledge by highly ordered rules reflecting man's evolution.

Development goes forward by stages of organisation, each stage supplanted by a later stage when usable conflict occurs in the attempted application of earlier rules. It is the concept of usable conflict that distinguishes the author's view from that of conventional learning theory, for encounters with the environment are shown to be effective in producing change only when the infant is able to code the disparity between his expectancies and what actually transpires as a result of his responding. The codability of such mismatches depends upon the development of rule structures for interpretation the result of maturation shaped by experience.

For Bower, the initial structure of space for the infant is supramodal, a space into which the special senses are mapped. Sufficient experimental evidence is presented to raise sharp questions about both Berkeley's and Piaget's accounts of the associative or conceptual welding of the disparate spaces of eye, ear, and hand. New and searching techniques of research are now available—many of them invented by the author—that suggest that the hand knows what the eye knows before it has had its own experience of reaching under visual control. "It is highly improbable", he argues, "that any organism evolved a visual system or an auditory system that was not an outgrowth of the supramodal perceptual system . . . the system that responds to those properties of objects that can be specified via any sensory modality." In like vein, primitive visual objects, although they are elaborated by 'experience' simultaneously to encompass more properties, begin as inherently organised representations including more than a single modality. Witness the distressed surprise of the infant at the beginning of his manipulatory career who reaches out for a vintual object produced by polarised light and polarising spectacles, and finds no tactual feedback on grasping the target. An older child is less surprised, having come to differentiate palpability from visual object qualities.

Bower then argues that at the earliest stage, as indicated by studies of eyemovement and reaching, the infant has two disparate systems for identifying and conserving the identity of objects. One is for objects in motion and is based on a smooth pursuit system; the other is for static objects and is based on the saccadic system. Only with maturation and with appropriate experience, Bower argues, do infants develop rules for dealing simultaneously with the two systems.

As far as cognitive development is concerned, it is conceived of as the development of rules and regulatory processes that serve to organise different features of input and to sequence classes of behaviour rather than specific behaviours. Bower argues that no specific single behaviour is ever found to be crucial to development; adequate 'manipulatory' behaviour seems to develop even in limbless thalidomide children who carry out reaching and prehensive tasks with their mouths and teeth. "It is more parsimonious to assume change in an underlying concept which generates all of the behaviours, than to assume separate independent changes in each behaviour." Cognitive development, then, is seen as the progressive growth of increasingly comprehensive and differentiated control systems for constructing and sequencing behaviour. Bower presents a brilliant series of experiments to illustrate his point, centred upon the development of the concept of an object; how it is recognised as the same object though undergoing transformations in appearance, locus, and even singleness of identity.

But for all its virtues and power, this book is flawed in a way that destines it to criticism and challenge. It is flawed, ironically, by an overextension of its virtues; its very clarity of premise and argument, capped by uncompromising conclusions, makes it vulnerable. It will serve for years as a source of ideas for doctoral theses that will prove it inconclusive theoretically and wrong or partially wrong experimentally. For, in fact, there are not yet enough findings in the field of infant cognitive research to justify the inferential depth of Bower's arguments or the boldness of his conclusions. And though the experiments—perhaps too closely focused on work at Edinburgh, Harvard, and Geneva-are highly ingenious, and often brilliant, many of them are neither easily reproducible nor yet as conclusive as the author believes. (Witness his reliance on a doubtful study by Wertheimer indicating that newborns can orient visually to a voice source in space; or the still questionable reproducibility of some of his own results.) Indeed, because of the clarity and depth of the premises, the crisply unqualified statement of the findings, and the forthrightness (at times recklessness) of conclusions, the book will provide both a paradigm for next stages of research-and a whipping boy.

Yet, however much it will be attacked as 'premature', it is a major synthesis of work on the "original nature of mind" and will rank as one of the major books on human development to be written during the last decade.

Jerome Bruner

#### Not so elementary

Introduction to Particle Production in Hadron Physics. By S. Humble. Pp. viii+253. (Academic Press: London and New York, 1974.) £6.80; \$17.50.

THERE are some subjects that cannot be taught. One can only learn them by experiencing their harsh realities oneself. And one can only face such a task when driven by powerful motivation or attracted by the hint of great excitement to be found along the thorny path. Just such a subject is particle production in hadronic interactions.

That the author of this book has succeeded in producing a clear and balanced exposition of an incredibly difficult topic, is noteworthy. That he has failed to generate in us the necessary desire and excitement is a pity.

It is an unhappy, but surely not an unexpected fact, that as elementary particles are made to collide at ever higher energies, more and more debris of an increasingly complicated character is found to emerge from the collision. It is by studying this debris that we are supposed to be able to deduce the structure and the dynamical properties of the colliding particles. But what a daunting task. Even a description of the debris (that is, of the momenta and energies of the emerging particles) is too complicated to comprehend. How do you communicate to someone your findings concerning the dependence of a scattering amplitude upon the 14 variables needed to characterise a final state of 6 particles?

It is well nigh impossible, therefore, to hope to work back from data to dynamics. Rather, one postulates a dynamical model and attempts to confront it with the data.

There are several models currently in vogue, all interesting, none very convincing. The author attempts to describe and compare them fairly comprehensively. I found the discussion of dual models very informative, especially the treatment of their predictions and of the difficulties involved in their computation. The section on the analytical properties of production amplitudes is particularly valuable, if only for the fact that it exposes the enormous complexity of the problems encountered. Multiperipheral and multiregge models are presented with a nice balance between essential fact and gory detail.

The text is marred by ugly typography (even an equation split between pages) and by many errors. I cannot refrain from seizing on the following sentence which most appropriately appears just below a typographical error: "Hence, it must always be a good idea in a practical calculation to

derive as much of the formalism as one can for oneself, rather than relying on even the most detailed texts."

Other points to carp at: too little physical motivation for the ideas of 'scaling' in inclusive reactions; too much emphasis on the original work of Lurçat and Mazur on phase-space integrals, when more modern and simpler techniques exist; a lack of depth and a certain banality in summarising the properties of the models.

All said, however, this is a useful book. It is a good attempt to come to grips with an enormously difficult subject. But—and this must be stressed—it is essentially a book for the would-be professional, and it demands more than a modicum of expertise in the theory of elementary particles.

E. Leader

An early bird: the little owl, first introduced into Britain—where it is still relatively uncommon—during the last century. From Birds. By Christopher Perrins. Pp. 176. (Collins: London, September 1974.) £1.95. One of a series of books which also includes Woodlands, by William Condry, and Life on the Sea Shore, by John Barret.

## **Encompassing the North Atlantic**

The Ocean Basins and Margins. (Vol. 2, The North Atlantic.) Edited by A. E. M. Nairn. Pp. xiv+598. (Plenum Press: New York and London, 1974.) \$45.60.

THE North Atlantic must be among the most comprehensively surveyed ocean basins; and in order to arrive at a picture of its age and evolution it is necessary to consider not only the marine geophysical data amassed in recent years, but also a century or more of detailed geological research on the bordering continents. A few earth scientists are able to keep abreast of this vast volume of data. The rest of us, I imagine, tend to rely on the available reviews; and, ideally, these should be compiled in one authoritative and up-to-date volume covering every aspect of the problem. The fact that this second volume in the series The Ocean Basins and Margins comes close to realising the ideal should make it a much sought-after book.

Sins of omission are generally few, though chapters on the palaeomagnetic data from the North Atlantic continents and on sedimentation would have been welcome, and the northern reaches of the ocean deserve more attention. A general criticism which can be levelled at this volume, in its role as a source book, is that some chapters make reference to work published in 1973, whereas others, judging from their reference lists, were completed and on the editor's desk in 1971. There was surely ample time for the latter to be brought more up to date, if only by following the example given in M. J. Keen's chapter, which includes an appendix of useful references published after the completion of the manuscript.

On the credit side, however, the book does cover much the greater part of what needs to be known about the North Atlantic. The editors set the scene in their opening chapter with a qualified acceptance of the 1972 Pitman and Talwani model for the evolution of the ocean basin. Stehli and Keen review the geology of the well known western margin (Bahamas to Newfoundland) and point out some of the problems which remain to be solved. Owen (Western Approaches to the British Isles), Vigneaux (Biscay) and Dillon and Sougy cover the eastern margins, the last of these authors contributing a particularly valuable summary of western African geology. The major oceanic islands-Azores (Ridley, Watkins and MacFarlane), Canaries and Cape Verde (Dillon and Sougy) and Iceland (Noe-Nygaard) -are all described, the last in a good review of the North Atlantic Cainozoic volcanism. Evidence for an older 'proto-Atlantic' is to be found in the Lower Palaeozoic orogenic belts of the northern Appalachians (Williams, Kennedy and Neale), southern Caledonides (Dewey), and Scandinavia (Nicholson). The account of the tectonics of Newfoundland and the summary of the British Caledonides are particularly good. Additional references to the Caledonian orogeny, and much useful data pertaining to the early history of the ocean basin of the present northern North Atlantic can be found in a clear

account of the geology of Greenland's Atlantic coast. Finally, Fitch, Miller, Warrel and Williams bring together the literature on tectonic and radiometric age comparisons across the North Atlantic and Noltimier rounds off the volume with a comprehensive review of the geophysics of the ocean basin.

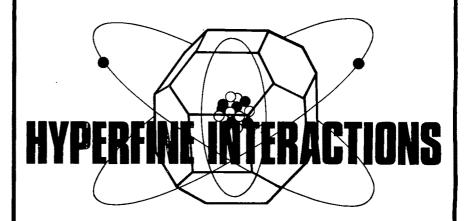

The book is well-produced, adequately illustrated, and there are extensive reference lists attached to each chapter. A subject index for the whole volume is provided, though a quick test of its usefulness revealed a "Silurian" entry which gives no page references for the Lower Palaeozoic orogens. The book contains the usual splattering of unimportant misprints, and one or two more serious gaffes, such as the ommission of the decimal points from the seismic wave velocities in Fig. 16 (p. 425). It is already somewhat dated, notably in relation to the marine geophysical and deep-sea drilling data published in the last couple of years. That is, however, inevitable and, with the reservations already mentioned, of no great significance. The important thing is that anyone now contemplating a study of the North Atlantic and its environs can have at his elbow one volume providing much of the necessary geological and geophysical background to his work. Every earth science library should have a R. J. Bailey copy of this book.

## Liquid scintillation counting

Applications of Liquid Scintillation Counting. By D. L. Horrocks. Pp. xiii+346. (Academic Press: New York and London, June 1974.) \$29.50; £14.15.

LIQUID scintillation counting originated 25 years ago when Ageno and his coworkers discovered that organic liquid solutions, when exposed to ionising radiation, emit scintillations which may be detected by a photomultiplier. Dr Horrocks' book provides an account of factors involved in internal scintillation counting. It also discusses applications of the technique, including chemiluminescence and bioluminescence, Cerenkov counting, pulse shape discrimination, flow-cell counting and large-volume counting. The discussion of quench correction unfortunately omits such topics as the relative quenching susceptibility of different scintillators, the different effects of impurity (chemical) and colour quenching, and the relative efficacy of the various quench correction methods. Nevertheless, the book can be recommended as a useful source of information on the applications of liquid scintillation counting. J. B. Birks

### announcing a new journal from North-Holland Publishing Co:

#### **Editors:**

H. DE WAARD, Physics Laboratory, University of Groningen, Groningen, The Netherlands B. DEUTCH, Institute of Physics, University of Aarhus, Aarhus, Denmark

#### Scope

The journal is concerned with research in the border regions of solid-state, atomic, and nuclear physics. Although the title and subject HYPER-FINE INTERACTIONS is one of the best examples of such a topic, other studies which utilize the modern techniques of atomic and nuclear physics may fall within the domain of the journal. The main concern is the understanding of border region physics, no matter what are the disguised variegated forms in which it appears.

The hyperfine interaction Hamiltonian is the logical basis for a large part of the subject matter to which this journal will be devoted because it contains products of atomic and nuclear quantities. In condensed matter, the Hamiltonian even spans solid-state physics. Hence such fields as: perturbed angular correlations, nuclear magnetic resonance, electric quadrupole resonance, beam-foil spectroscopy, nuclear orientation, and Mössbauer effect studies fall immediately within the journals domain. In addition, any atomic or solid-state studies via hyperfine spectroscopy (utilizing mesons, gamma rays, electrons, etc.) are within the scope. It can include problems related to solid, liquid and gaseous states as well as studies with biological material.

The title HYPERFINE INTERACTIONS is not meant to prevent contributions that do not directly involve such interactions from reaching the journal. For example, the journal is receptive to particle-beam studies which also explore the border physics region but

do not necessarily utilize hyperfine effects. Under this category lie channeling, nuclear lifetimes studied via channeling and implantation phenomena. In fact, studies which incorporate one of the disciplines of physics: solid-state, atomic or nuclear physics to study another would be generally acceptable.

#### Advisory editorial board

An editorial board is being formed and to-date the following scientists already accepted our invitation: B. Herskind, Copenhagen; E. Matthias, Berlin; J. A. Davies, Chalk River; N. Stone, Oxford; E. Bodenstedt, Bonn; G. Goldring, Rehovat; V. I. Goldanski, Moscow; T. Yamazaki, Tokyo;

#### Invitation to authors

The editors cordially invite colleagues to submit papers for publication within the scope of the journal. It should be realised that the refeering criteria will be high. Guidelines for preparing the manuscripts are available from the editors and publisher. Contributions should be sent to B. Deutsch, University of Aarhus.

#### Subscription information

The journal will be published in volumes of 6 issues; each issue will contain some 100 pages, first issue is scheduled to appear in spring 1975; In principle the journal will appear bimonthly. Subscription price: US\$42.50, Dfl.110.00 per volume, postage individed. Specimen copies will be supplied by the publisher.

Date ....

north-holland

#### Classified Advertisements

Classified Advertisements
CONDITIONS. All advertisements will only be accepted on the condition that the advertiser warrants that the advertisements do not in any way contravene the provisions of the Trade Descriptions Act 1968 and the Race Relations Act 1968. The Publisher also reserves the right to refuse, amend, withdraw or otherwise deal with all advertisements submitted to him at his absolute discretion and without explanation. All advertisements must comply with the British Code of Advertising Practice.

The Publishers will not be liable for any loss occasioned by the failure of any advertisement to appear from any cause whatever, nor do they accept liability for printers' errors, although every care is taken to avoid mistakes. Semi-displayed £4.10 s.c.c. Minimum 3 cm. Full page £260.00. Half page across £145.00. 30p is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, I Clement's Inn, London, WC2A 2ED. Telephone: 01-242 6264. Telegrams: Textualist, London, W.C.2.

#### APPOINTMENTS VACANT

#### THE DEPARTMENT OF PSYCHOLOGY PRINCETON UNIVERSITY

PRINCETON UNIVERSITY
anticipates several openings for the 1975-76
academic year. One is at the Full Professor level
in social psychology, where we seek an addition
to our ongoing programme in social psychology.
The other(s) at the Assistant Professor level are in
general experimental psychology, with concentration
in animal behaviour, developmental and comparative psychology, or personality research. These
latter anticipated openings are not rigidly tied to
any specific area of expertise. Sheer excellence in
research and teaching will override area-of-interest
considerations.

Nominations and applications should be sent to
the Chairman, Department of Psychology, Green
Hall, Princeton University, Princeton, New Jersey
08540. We are an equal opportunity employer with
a vigorous affirmative action programme. (2022)

#### ISLE OF MAN DIVING TECHNICIAN

DIVING TECHNICIAN

A Diving Technician is required at the University of Liverpool Marine Biological Station, Port Erin, for a period of two years to work on a project financed by the Wolfson Foundation to investigate the biological feasibility of farming scallops in cages in the sea. The work will involve much SCUBA diving and boat work. Applicants should hold at least a B.S.A.C. 3rd Class Diver qualification or equivalent. Some knowledge of biology might be advantageous but diving experience, a practical aptitude and enthusiasm are more important. Initial salary will be up to £1,860 per annum. Further particulars and application forms, which should be returned as soon as possible, may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/328/N. (2095)

#### FACULTY POSITION IN THEORETICAL ASTROPHYSICS AT CALTECH

The California Institute of Technology invites applications for the position of Assistant Professor of Theoretical Astrophysics. Applicants should have outstanding research abilities, as evidenced by publications and by strong recommendations from colleagues. We are particularly interested in applicants who will interact closely with our observational astronomers (radio, millimeter, infrared, optical, X-ray, and cosmic ray). However, we shall also consider outstanding applicants with research not tied closely to observations. Teaching ability will be taken into account in evaluating applicants.

research not tied closely to observations. Teaching ability will be taken into account in evaluating applicants.

Catech is an Equal Opportunity Employer with an Affirmative Action Program. We encourage applications from women and members of minority groups.

Letters of application should be sent to Maarten Schmidt, Executive Officer for Astronomy, California Institute of Technology, Pasadena, California 91125. Applications should include (1) a description of educational background; (2) a resume of research and teaching experience; (3) a list of all publications; (4) copies of all manuscripts submitted for publication but not yet published; (5) a statement of current research interests and future research plans; (6) a list of at least six astronomers or physicists who can evaluate the applicant's research, including at least three who know the applicant personally. The applicant should ask the latter three to send letters of evaluation directly to Professor Schmidt. All materials should reach Caltech before February 1, 1975. (2098)

#### **NEW HEBRIDES**

#### AGRICULTURAL EXTENSION **OFFICERS**

Required by the Department of Agriculture to take charge of an Extension Sub-District. The work is mainly concerned with New Hebrides producers and will involve touring among the islands by

Candidates should possess an Agricultural Degree or Diploma with at least 3 years good practical agricultural experience, preferably in the tropics. Some knowledge of French is necessary.

Appointment is on agreement for two to three years initially. Commencing salary according to experience in a scale approximately equivalent to £2,980 to £6,470 p.a., which includes an allowance, normally tax-free, in a scale £546 to £1,938. Benefits include gratuity of 25% of basic salary, free passages, generous leave, education allowance, children's holiday visit passages and rent free quarters. A car loan up to £600 and an appointment grant up to £300 may also be payable.

There is no income tax in the New Hebrides at present.

The post described is partly financed by Britain's programme of aid to the developing countries administered by the Ministry of Overseas Development.

For further particulars you should apply, giving brief details of experience to:

## crown agents

M Division, 4 Millbank, London SWIP 3JD, quoting reference number MID/740207/NF.

#### UNIVERSITY OF BRISTOL DEPARTMENT OF ANATOMY

The University invites applications for TWO LECTURESHIPS

in the Department of Anatomy. The posts are now vacant and may be taken up as soon as possible. For one of these appointments, preference will be given to candidates with an interest in developmental biology, and for the other, an interest in neurobiology. The Department is well-equipped for research in these areas. Candidates will be expected to take part in the research, teaching, and other activities of the Department. Salary will be within the range £2,118 to £4,896 or £3,462 to £4,896 (medically qualified) according to qualifications and experience. Applications, together with the names and addresses of two referees, should be sent not later than January 6, 1975 to the Secretary, Senate House, University of Bristol, Bristol BS8 1TH, from whom further particulars may be obtained (reference TLJ).

#### PAHLAVI UNIVERSITY DEPARTMENT OF BIOLOGY SHIRAZ, IRAN

SHIRAZ, IRAN

Applications are invited at the assistant/
associate professor's level for the following
positions on two year renewable contracts with an
annual salary range equivalent to U.S. \$12,000 to
U.S. \$16,000; depending on qualifications and
teaching experience.

Please send written applications, curriculum
vitae and confidential recommendations from
three referees to the Department of Biology,
Pahlavi University, Shiraz, Iran.

Applications are invited for the following fields:

1. Bacterial/Viral genetics
2. Developmental genetics
3. Cell organelle physiology
4. Plant Biochemistry
5. Animal physiology: osmoregulation

Plant Biochemistry •
Animal physiology: osmoregulation
Ornithology
Insect physiology
Plant growth regulators
Invertebrate zoology/protozoology
Terrestrial animal ecology/plant ecology
Echthology

Ichthyology Reproductive physiology Vertebrate neurophysiology

13. Vertebrate 14. Mycology

#### UNIVERSITY OF NEW SOUTH WALES

#### BIOCHEMIST/MICROBIOLOGIST/ MICROBIAL GENETICIST

(Lecturer—School of Biological Technology)

Technology)

The School practises a multi-disciplinary approach to Biological Technology and conducts research and teaching programmes in applied microbial genetics, microbiology, biochemistry (including enzyme technology) and biochemistry (including enzyme technology) and biochemistry and microbial genetics and considerable research experience in one, or preferably a combination, of the areas of study indicated. Successful applicant should have strong interests in projects of a potentially or directly applied nature. Duties will include formal undergraduate and postgraduate teaching and supervision of higher degree candidates. Appointment from February 1975.

Salary (under review): \$A9,002 to \$A12,352 per annum. Commencing salary according to qualifications and experience.

Details of appointment, including suberannuation, study leave and housing scheme, may be

Details of appointment, including sufferannuation, study leave and housing scheme, may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H OFF.

Applications close in Australia and London on Janeary 17, 1975.

(2105)

#### UNIVERSITY OF LIVERPOOL RESEARCH ASSISTANT

RESEARCH ASSISTANT

Applications are invited from graduates with previous research experience particularly in biochemistry or a related discipline for a post of Research Assistant in the Department of Dental Sciences. The post to commence early in 1975 is financed by the Medical Research Council as part of a group studying the metabolism of sulphated glycoproteins of oral origin and is tenable in the first instance until October, 1976. Salary plus Threshold Supplementation and the option will be in the range £1,761 to £2,019 per annum of F.S.S.U. benefits.

Applications stating age, academic qualifications and experience together with the names of two referees should be received as soon as possible by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX. Quote ref. RV/323/N. (2111)

(2100)

## Cytochemist/ **Histochemist**

Required to head a mixed team of cytologists and chemists in work ranging from fundamental investigation into cell behaviour to the creation and evaluation of preparation techniques. A good understanding of cytology and organic chemistry is necessary together with the ability to organise a mixed discipline team working in collaboration with a computer based pattern recognition group. Many fields of R & D could have given candidates a suitable background but they must have enthusiasm, initiative and independence to advance this vital part of the Company's technology.

The Company's well equipped modern laboratories provide excellent working conditions and leisure facilities in pleasant rural surroundings ideally related to London and nearby Cambridge. Superannuation, sickness and life assurance schemes; B.U.P.A. group; tennis court; swimming pool; substantial re-settlement expenses, and generous salary. Contact the Technical Director for further information and an application form, quoting D/D79.

Image Analysing Computers Ltd., Melbourn, Royston, Herts. SG8 6EJ. Tel: Royston 60611 (STD 0763).

(2123)

#### UNIVERSITY OF MELBOURNE CHAIRS IN BIOLOGICAL SCIENCES

The retirement of Professor Michael J. D. White F.R.S., F.A.A., at the end of 1975 and the appointment of Professor Geoffrey Burnstock F.A.A. to the Chair of Anatomy in University College London, will leave two chairs vacant in the biological sciences.

Applications for these chairs are invited from persons distinguished in research in any field of genetics or zoology or allied fields such as cell, developmental or molecular biology or animal ecology.

cell, developmental of indicedual viology of animal ecology.
Salary: SA19,614 per annum (under review).
Further information about the positions, including details of application procedure, superannuation, travel and removal expenses, housing assistance and conditions of appointment, is available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, Londo WCIH 0PF.

Applications close on February 28, 1975.

#### THE UNIVERSITY COLLEGE OF WALES **ABERYSTWYTH** DEPARTMENT OF AGRICULTURE

A.R.C. RESEARCH ASSISTANT

required to work on aspects of winter cauliflower

production.

Applicants should have a good Honours degree in Horticulture, Agriculture or Agricultural Botany and the successful candidate will be required to assist with research on winter cauliflowers at the Department's Field Station at Trefloyne, Terphy

Salary from: £1,070 p.a. (plus dependants' allowance for those registering for a higher degree).

Further particulars and application forms may be obtained from the Registrar. Closing date: December 19, 1974. (2124)

#### UNIVERSITY OF BRISTOL DEPARTMENT OF CHILD HEALTH LABORATORY OF IMMUNOLOGY

Dr. Walter C. Henneberger, Chairman, Department of Physics and Astronomy, Southern Illinois University at Carbondale, Carbondale, Illinois 62901, U.S.A.

SOUTHERN ILLINOIS UNIVERSITY

AT CARBONDALE

Teaching assistantships and a number of fellow-ships are available to qualified students who wish to pursue a program leading to the M.S. or M.A. degree in Physics. Excellent research facilities

M.A. degree in Physics. Excellent research facilities are available in atomic and molecular spectroscopy (molecular spectroscopy and structure; spectroscopy of metastable atoms: visible, infrared and 'Raman spectroscopy of solids; semiconductors; laser induced chemical reactions; far infrared spectroscopy; bio-polymers; upper atmospheric physics); high energy physics (in cooperation with Argonne National Laboratory); and theoretical physics (quantum optics, group theory, atomic physics, interaction of intense radiation with matter, statistical mechanics). Excellent library and computer facilities exist. For further details contact:

LABORATORY OF IMMUNOLOGY

A POSTDOCTORAL BIOCHEMIST, preferably
with 2-3 years experience, is required in the
Laboratory of Immunology of the above department to purify and characterize the properties of
a new, and probably inherited, salivary substance
which is a serologically independent of the ABO,
Lewis and Sda blood group systems.
Commencing salary up to £2.412 per annum
plus Threshold supplements, depending on experience. The appointment will be funded by an
M.R.C. grant which runs for three years.
Applications, including curriculum vitae and
names and addresses of two referees, should be
sent to Professor N. R. Butler, Department of
Child Health, St. Michael's Hill, Bristol BSZ 8BJ.
(2132)

#### DALHOUSIE UNIVERSITY

Department of Pharmacology

Department of Pharmacology

Applications are invited for a POSTDOCTORAL FELLOWSHIP in one of the following fields:

(i) Cardiovascular of Pharmacology, (ii) Toxicology of Environmental Pollutants, (iii) Transport of neurotransmitters and electrolytes into presynaptic nerve terminals, (iv) Autonomic Pharmacology and Electrophysiology of Smooth Muscle.

Applicants, should not be more than 35 years of age, and should hold a Ph.D. degree with specialisation in one of the above mentioned areas from a recognised university. Initially this fellowship is granted for one year only, the annual stipend being \$9,100 (presently under revision) and subject to income tax. Travel grants may be provided to the fellow and spouse, if married.

Applications must be received no later than January 30, 1975, togither with a list of publications, curriculum vitae and at least two letters of recommendation to be sent directly from persons well acquainted with the applicant's personal and academic record to: Dr J. G. Aldous, Chairman, Department of Pharmacology, Sir Charles Tupper Medical Building Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7.

#### UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS

Applications are invited for the post of Post-doctoral Research Assistant from January 1, 1975 or as soon as possible thereafter. The successful candidate will be expected to pursue a research and development programme involving the application of neon flash tubes to nuclear particle detection with special reference to high energy gamma radiation. The programme will involve work at tion. The programme will in Science Research Council's involve v l's high

The appointment, which is funded by the Science Research Council, will be for a period of two

The salary will be on the scale from £2,055 to £2,793, plus threshold payments and F.S.S.U. benefits.

benefits.

Applications (3 copies) including the names and addresses of three referees should be sent by December 16, 1974 to the Registrar and Secretary, Science Laboratonies, South Road. Durham, DH1 3LE, from whom further particulars may be obtained. (2107)

#### UNIVERSITY OF LONDON INSTITUTE OF PSYCHIATRY POSTDOCTORAL NEUROCHEMIST

#### NEUROPHARMACOLOGIST

NEUROPHARMACOLOGIST

The appointment, which is for three years, is in the University Department of Neurology at the Institute of Psychiatry with an honorary contract at the M.R.C. Clinical Research Centre. Northwick Park, where some of the studies will be undertaken. The principal objectives are the study of the functions and inter-relations of folic acid and vitamin B12 in the nervous system including relationships to amine metabolism and the effect of anticonvulsant drugs. These studies will complement clinical investigations which are already in progress.

Starting salary within the range £2,311 to £3,144 including London Weighting according to qualifications and experience.

including London Weignung accounting fications and experience.

For application forms and further information please write to the Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London, SE5 8AF or telephone 01-703 5411 ext. 228.

(2112)

#### VISITS TO INDIA FOR YOUNGER SCIENTISTS AND SOCIAL **SCIENTISTS**

Applications are invited from suitably qualified British scientists, engineers and social scientists to visit India under the Younger Scientists Exchange Scheme. This Scheme is designed to promote mutual understanding and the formation of professional links between personnel in Indian and British universities and to facilitate the exchange of information and lides

versities and to facilitate the exchange of information and ideas.

Visits should preferably be of three months duration to enable a useful programme of work to be carried out, although in exceptional cases applications for shorter periods will receive consideration. Applicants should hold a staff appointment at a university, polytechnic or similar institution and preferably be aged between 27 and 35 years. Return tourist class air fares will be paid by the British Council and the Indian University Grants Commission will provide an honorarium to cover local expenses.

Grants Commission will provide an indicatual to cover local expenses.

Further information and application forms for wisits between late July 1975 and February 1976 may be obtained from the Director. Science Department, The British Council, 10 Spring Gardens, London SWIA 2BN. The closing date for applications will be January 31, 1975. (2135)

#### (PERSONNEL PLACEMENT, POSITION OPEN) VASCULAR-PLANT SYSTEMATIST HAWAII

Assistant or Associate Professor, Interests in tropical, Pacific and Asian plants; in a biosystematic and experimental approach to research; and in graduate and undergraduate instruction. Details available from Dr N. P. Kefford, Chairman, Department of Botany, 3190 Maile Way, University of Hawaii, Honolulu, Hawaii 96822. U.S.A. An Equal Opportunity/Assirmative Action Employer. (2122)

#### DEPARTMENTAL RESEARCH **ASSISTANT**

ASSISTANT

A Departmental Research Assistant is required to take charge of a Techniques Laboratory concerned with the preparation of targets and counters for Nuclear Physics experiments. Close collaboration with research staff and students using the Oxford accelerators is essential and some experience with Nuclear Physics apparatus and techniques is desirable, although not essential.

Applicants, who should be University graduates (preferably with Ph.D.), should write to Professor K. W. Allen, Nuclear Physics Laboratory, Keble Road, Oxford OX1 3RH. (2129)

#### UNIVERSITY OF THE WEST INDIES TRINIDAD

TRINIDAD

Applications are invited for the post of PRO-FESSOR OF AGRICULTURAL ECONOMICS in the Department of Agricultural Economics and Farm Management. Preference will be given to persons competent in quantitative economics and with broad training and experience in other aspects of Agricultural Economics. Duties will include teaching both undergraduate and postgraduate students and the supervision of research students Salary scale: TTS27,636 to TTS34,980 p.a. (£1 sterling=TT\$4.8). F.S.S.U. Unfurnished accommodation at rent of 10% of salary for maximum of three years; thereafter 20% of salary payable in lieu of housing. Family passages. Study and Travel Grants are also payable. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, as soon as possible to the Secretary, University of the West Indies, St Augustine, Trinidad, Further particulars will be sent to all applicants. (2146)

#### UNIVERSITY OF BRISTOL SCHOOL OF CHEMISTRY POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited from Chemists or Physicists for an S.R.C. Postdoctoral Research Assistantship to work in the field of electronic laser resonance spectroscopy. The project will use a high resolution dye laser in studies of hyperfine structure, excited state dipole moments, and line widths of electronic spectra of polyatomic molecules

The appointment will be for one year in the first instance, with a posible extension to two years. Salary range up to £2,247 per annum plus Threshold supplements.

Applications with curriculum vitae and names of two referees to Professor R. N. Dixon, School of Chemistry, Bristol University, Bristol BS8 17S.

(2133)

#### UNIVERSITY OF ZAMBIA

UNIVERSITY OF ZAMBIA

Applications are invited for posts of (i) PROFESSOR/SENIOR LECTURER/LECTURER IN SCIENCE TEACHING METHODS and (ii) PROFESSOR/SENIOR LECTURER/LECTURER IN SCIENCE TEACHING METHODS in the School of Education. Applicants should possess a relevant first degree, a postgraduate teaching qualification and higher degree as well as experience in secondary school teaching. Preference will be given to those with teacher training experience in a frican countries. Salary scales: Professor K7,400 to K7,800 p.a. Senior Lecturer K5,600 to K6,600 p.a. Lecturer K4,000 to K5,400 p.a. (£1 sterling=K1.49). The British Government may supplement salaries of all married appointees in range £516 to £1,152 p.a. (sterling) or supplement salaries of single appointees to the levels of Senior Lecturer and Professor in range £78 to £204 p.a. (sterling) and provide children's education allowances and holiday visit passages. This supplementation is unlikely to be provided to single appointees to Lecturer level. Family passages; various allowances; superannuation and medical aid schemes; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 refereees, should be sent by airmail, not later than January 6, 1975 to the Registrar, University of Zambia, P.O. Box 2379; Lusaka, Zambia, Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London WIP 0DT. Further particulars may be obtained from either address.

## **Glaxo**

## Technical Officer-Fermentation Development ULVERSTON, CUMBRIA

We have a vacancy for a Technical Officer, who should either have an HNC or a first degree qualification. A sound knowledge of Analytical Chemistry is essential. Candidates must have initiative and should be versatile: any experience in Microbiology, Automatic Instrumentation. Electronics or Control Systems would be advantageous.

The Fermentation Development Department is essentially interdisciplinary and conducts investigations in Microbiology, Genetics, Biochemistry, Fermentation and Biochemical Engineering in support of the production of antibiotics, Vitamin B12 and Enzymes. The Analytical Section provides a range of service facilities and initiates Analytical development including novel approaches to automation and the continuous monitoring and control of fermentations.

The salary will be according to age and experience.

The Company offers good conditions of service including bonus, pension and sick pay schemes. Ulverston is a pleasant market town situated on the southern fringe of the Lake District National Park.

Please apply in writing to:

The Personnel Officer (JE), Glaxo Laboratories Limited, North Lonsdale Road, Ulverston, Cumbria, LA12 9DR.

(2128)

#### UNIVERSITY OF CAMBRIDGE DEPARTMENT OF ENGINEERING

#### RESEARCH ASSISTANT IN EXPERIMENTAL AERODYNAMICS

The Head of the Engineering Department hopes to appoint a research assistant to conduct experimental investigations into problems connected with aircraft engine components. The post is supported by industry at a salary up to £3,636 p.a. plus threshold, depending on qualifications. Qualified applicants will have an honours degree in Engineering or Physics, Applications, together with curriculum vitae and the name of a referee, should be sent to the Secretary, Faculty of Engineering, Trumpington Street, Cambridge CB2 1PZ, not later than January 1, 1975. (2134)

#### THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY DEPARTMENT OF CHEMISTRY EXPERIMENTAL OFFICER (Ref: CH/108/R/AI)

(Ref: CH/108/R/AI)

Applications are invited for the post of Experimental Officer in the Department of Chemistry to be responsible for the operation of an Electron Spin Resonance Spectrometer, and to participate actively in the teaching and research programmes with which it is concerned.

The post will be particularly attractive to candidates who can combine an interest in and practical knowledge of electronics with a high level of organic and inorganic chemical ability including research and development experience and interest in reactive intermediates and mechanistic aspects of chemistry. in reactive intermediates and of chemistry.

Salary within the scale: £1,758 to £3,114 with

F.S.S.U. Requests for application forms to the Registrar, U.M.I.S.T., Sackville Street, Manchester M60 1QD, to be returned not later than January 18, 1975. (2140)

#### UNIVERSITY OF THE WEST INDIES **JAMAICA**

Applications are invited for (a) LECTURESHIP (b) ASSISTANT LECTURESHIP IN THE DEPARTMENT OF ZOOLOGY, tenable as soon DEPARTMENT OF ZOOLOGY, tenable as soon as possible. Preference will be given to persons with an interest in marine ecology Salary scales: (a) J\$6,168 to J\$9,768 p.a. (b) J\$5,006 to J\$5,486 p.a. (£1 sterling=J\$2,11). F\$S,U Study and Travel Grant. Unfurnished accommodation at rent of 10% of salary for maximum of three years, thereafter 20% of salary payable in lieu of housing Family passages. Detailed applications (6 copies), including a curriculum vitae and naming 3 geferees, should be sent by air mail, as soon as possible to should be sent by air mail, as soon as possible to the Registrar, University of the West Indies, Kingston 7, Jamaica. Detailed particulars are avail-able and should be obtained from the same source before an application is made.

#### DEPARTMENT OF ANATOMY UNIVERSITY OF CAMBRIDGE

UNIVERSITY OF CAMBRIDGE.

Applications are invited for a postdoctoral research associate position to work on lymphocyte trapping at the placental focto-maternal interface during pregnancy; this work is part of a general project involving investigation of immunological relationships in pregnancy, and the application of immunological techniques to developmental studies. Applicants should preferably have experience in handling and separation of sub-populations of lymphocytes; some experience in embryology would be helpful but is not essential. The post is available for one year in the first instance, with a starting salary of approx. £2,400, and starting on January 1, 1975 or as soon as possible thereafter. Applicants should send details to Dr. M. H. Johnson, Department of Anatomy. Downing Street, Cambridge CB2 3DY, and include a full curriculum vitae, publications, the names of two referees etc. as soon as possible. (2150)

## CHROMATOGRAPHY IN DRUG RESEARCH

The role of Central Research's Analytical Chemistry department is to devise and develop methods to control potential new drugs from their discovery to marketing. A principal aim is the generation of technical data for submission to world-wide regulatory agencies.

To maintain the technical support currently required we need an additional chemist to work as a chromawe need an additional chemist to work as a chromatography specialist, supervising the activities of two members of staff. The range of duties is varied and includes the application of GLC, HPLC and TLC to a wide variety of problems including homogeneity assessment, the quantitative control of impurities and stability studies. The job involves collaborating with a large number of research staff, and provides an excellent opportunity to gain a wide experience of separation science in a pharmaceutical research environment.

The successful applicant will probably have had about ten years post-qualification (BSc., G.R.I.C.) experience, be used to supervising and training junior staff and command a starting salary of c. £3,500.

Salaries are reviewed annually, and a bonus scheme in operation. Other terms of employment include pension and death benefit schemes, flexible working hours, and considerable financial assistance with removal expenses.

Our laboratories are situated in a pleasant coastal/ rural area at Sandwich, Kent.

Applications, giving brief details of age and experience should be addressed to:

D. W. Sells. Personnel Manager, Central Research, Pfizer Limited. Sandwich, Kent.

(2137)

#### RESEARCH ASSISTANT

RESEARCH ASSISTANT

Applications invited for the post of research assistant to study the mechanisms of resistance and susceptibility of wheat to rust fungi. The work envisaged is at the biochemical level and is supported by the Agricultural Research Council.

Applicants should have had at least three years post-graduate research experience in Botany, Biochemistry or Microbiology but not necessarily Plant Pathology, although some knowledge of this subject could be an advantage. Salary within range £2,118 to £2,412 p.a. plus F.S.S.U. if appropriate, £213 London Allowance (under review) and Threshold payments.

Application by December 27 with a curricultum vitae and the names of two referees to Dr R. N. Strange, Department of Botany and Microbiology. (N) University College London, Gower Street, London WC1E 6BT. (2149)

#### RESEARCH ASSISTANT

• RESEARCH ASSISIANI
required for studies of radiation effects on an experimental chondrosarcoma in the Department of Physics. Graduate in biological subject preferred with good Honours degree. Successful candidate may register for a higher degree. Salary £1,698 p.a. plus 2 by £79 and threshold allowances. Applications, with names of two referees, to Dr N. F. Kember, Dept. of Physics, The Medical College of St. Bartholomew's Hospital, Charterhouse Square, London, ECIM 6BQ, quoting reference 688. (2138)

#### **ELECTRONICS TECHNICIAN** (Grade 5)

required for small research group in Zoology and Comparative Physiology Department, investigating ultrasonic communication and echolocation systems of animals. Responsibilities will include maintenance of various advanced instruments and the development of new equipment and techniques for investigating ultrasound in air. The appointment is temporary for one year in the first instance. Salary scale £2,439 to £2,895 p.a. plus £228 p.a. London Weighting. Five weeks in total annual leave. Five day week. Letters only to Assistant Secretary (Establishment) ET/Z, Queen Mary College, Mile End Road, E1 4NS, stating age, qualifications and experience. (2113)

#### UNIVERSITY OF LEEDS

DEPARTMENT OF **EXPERIMENTAL** PATHOLOGY AND CANCER RESEARCH

Applications are invited for the post of POSTDOCTORAL RESEARCH FELLOW to work in collaboration with Dr R. C. Garner on the development of short-term tests for chemical carcinogens.

Candidates should have a background in tissue culture techniques and would be expected to carry out research on nuclear changes induced by carcinogenic and non-carcinogenic chemicals in mammalian cells.

The appointment, which is sponsored by a Medical Research Council grant, will be for up to three years within the salary range of £2.118 to £2.757 plus F.S.S.U. depending on age and experience, and commencing on January 1, 1975 or as soon as possible thereafter.

Applications in writing, giving full details of career etc. together with the names of two academic referees should be sent by December 18 to the Registrar, The University of Leeds, Leeds LS2 9JT quoting reference 89/1. (2092)

#### UNIVERSITY OF READING GRADUATE

#### RESEARCH ASSISTANT

required in Department of Zoology, from January I to join a small team studying the ecology of chalk streams. The post involves field and laboratory work. Starting salary in range £1,500 to £2,000 p. a. Apply to Dr J. F. Wright, Department of Zoology, University of Reading, Whiteknights, Reading RG6 2AJ, from whom further constitutions are provided by the control of particulars are available, (Ref: MN 58). (2164)

#### UNIVERSITY OF SYDNEY LECTURER IN AGRONOMY (Crop Nutrition)

A lecturer is required in the general field of the mineral nutrition of crops. Applicants should hold a first degree in science or agricultural science, and a Ph.D. or equivalent research interests and experience in the discipline. The Department has 15 academic positions and by mid-1975 will be housed in new laboratories and offices. In addition there are excellent facilities for teaching and research at the Department's Field Stations (Camden, New South Wales).

The position advertised is permanent but may

The position advertised is permanent but may be filled for three years in the first instance with possibility of renewal after that date, or in certain cases return fares.

Salary range: \$A9,002 to \$A12,352 p.a.

Saiary range: 5A9,002 to \$A12,352 p.a. Applications, including curriculum vitae, list of publications and 'names of three referees, by January 6, 1975, to the Acting Registrar, University of Sydney, New South Wales 2006, Australia, from whom further information is available. Information also available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H OPF. (2156)

#### CHELSEA COLLEGE UNIVERSITY OF LONDON

Applications are invited for the post of Laboratory

#### **TECHNICIAN** (Grade 4)

in the Department of Physiology of the Basic Medical Sciences Group. We are looking for someone with appropriate qualifications and experience. The successful candidate should have experience of electrophysiological and medical instrumentation and be willing to make his contribution to experimental classes and research in the Department, Salary Scale: £2,475 to £2,856 (including £228 London Weighting, which is under review)

#### UNIVERSITY OF ST. ANDREWS

Botanic Garden: Department of Botany

Botanic Garden: Department of Botany
Applications are invited for the post of
Records Officer/Taxonomist, who will be
responsible to the Curator for the maintenance of the records and the identification
of plants in the Botanic Garden. A qualification in Botany or Horticulture with taxonomic interests is required. Appointee may be
registered for a research degree in the
Botany Department. Salary scale £1,860 to
£2,187. Further information may be obtained from the Curator, University Botanic
Garden, St. Andrews, KY16 8RT. Applications, stating qualifications and experience
and giving the name of a referce, should
be submitted to the Establishments Officer,
University of St. Andrews, College Gate,
St. Andrews, Fife, KY16 9AJ, by December
16, 1974. (2119)

#### MEMORIAL UNIVERSITY OF NEWFOUNDLAND

HEAD OF THE DEPARTMENT OF GEOLOGY

The Memorial University Geology Department has 18 faculty members, a full technical and secretarial staff, 25 graduate students, and about 60 undergraduate majors. In 1975, it will occupy 40,000 square feet in a new building, which will contain a range of teaching and research laboratories and equipment (flume tank, XRF, XRD, microprobe, etc.).

Recent research in the December 18

microprobe, etc.).

Recent research in the Department has been dominantly within the context of Appalachian and Labrador studies, but there has lately been a broadening of approach, especially in marine and sedimentary geology.

No specific field of research is required for the new Department Head, but the suitable candidate must be a highly competent scientist with an ability to understand and encourage a wide range of geological research, much involving close cooperation with other University departments, government and industry. Enquiries should be addressed to Dr D H. Rendell, Associate Dean of Science, Memorial University of Newfoundland, St. John's, Newfoundland, Canada, AIC, 557.

Applications should be received by January 31,

Applications should be received by January 31, 1975. (2157)

#### UNITED KINGDOM ATOMIC ENERGY AUTHORITY

#### INFORMATION **OFFICER**

(HIGHER SCIENTIFIC OFFICER)

Applications are invited for the post of Information Officer in the Library and In-formation Department of the Reactor Group Headquarters, Risley, Warrington.

The duties of the post involve informa-tion searches in a wide range of technical, scientific and commercial literature; monitor-ing journals for references for a weekly bulletin and subject-indexing of specialised reports.

The work requires tireless curiosity and a desire to help engineers, scientists and managers by tracking down information for them in the literature.

The successful candidate will have the use of two large modern libraries of reports and published literature, staffed and managed by qualified personnel.

#### QUALIFICATIONS:

Experience of information work is desirable. In addition, candidates should have a degree, HNC or HND in a scientific, mathematical or engineering subject, or equivalent qualifications in library and information work.

£2,635 on a scale rising to a maximum of £3,610 per annum plus "threshold" pay agreement which, at present, provides a supplement of £13.92 a month.

Please write for application form, quoting reference S608A/J.14 to Staff Officer, Room E303, United Kingdom Atomic Energy Authority, Reactor Group Headquarters, Risley, Warrington, WA3 6AT.

Closing date for the return of application forms: December 24 1974. (2094)

#### UNIVERSITY OF DUBLIN Trinity College

#### CHAIR OF MICROBIOLOGY

Applications are invited for appointment to this Chair, which will fall vacant on July 1, 1975.

Further particulars may be obtained from:

The Secretary to the College West Theatre Trinity College Dublin 2.

Formal applications should, if possible, reach the Secretary (2061)before January 6, 1975.

#### CENTRAL & SOUTHERN HEALTH DISTRICT (Teaching) LIVERPOOL A.H.A. (T)

#### BASIC GRADE BIOCHEMIST

required at

DEPARTMENT OF CHEMICAL **PATHOLOGY** ASHTON STREET, LIVERPOOL 3

Salary scale £1,689 rising to a maximum of £2,994 per annum.

Application form and job description obtainable from the District Administrator, 80 Rodney Street, Liverpool, L1 9AP, to be returned by December 27, 1974. (2131)

#### THE UNIVERSITY OF **MANCHESTER**

#### RESEARCH ASSISTANT IN OCCUPATIONAL HEALTH

Applications invited from mechanical or aeronautical engineers, or candidates qualified in fluid mechanics, to study the air flow in the alveoli of the human lung. Opportunities exist to register for a higher degree. Salary according to qualifications and experience. Post tenable for up to 3 years. Further particulars and application forms (returnable by December 20) from the Registrar, The University, Manchester, M13 9PL. Quote ref: 245/74/N. (2160)

#### THE CITY UNIVERSITY

**Department of Chemistry** 

#### POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from suitably qualified candidates in materials science or electrochemistry to work on an S.R.C. sponsored project on Semiconducting Oxide Anodes,

The starting salary will be on the scale £2,118 to £2,580 per annum plus £213 London Allowance and threshold payments of £229.68 per annum.

Please apply to Dr A. C. C. Tseung, Department of Chemistry, The City University, St. John Street, London, (2143)

#### "METALS ABSTRACTS"

The international abstracting service for metallurgy offers permanent positions as SENIOR EDITORIAL ASSISTANTS The work consists of editing and checking abstracts for publication. A science degree, preferably in metallurgy, physics, or chemistry, is necessary and a working knowledge of a foreign language would be an advantage.

Applications, stating age, education, qualifications, and experience, to Dr T. Graff, Metals Abstracts, The Metals Society, 1 Carlton House Terrace, London SWIY 5DB

(2148)

#### WELSH NATIONAL SCHOOL OF MEDICINE RESEARCH ASSISTANT

required in the Department of Dermatology required in the Department of Dermatology to work on the physical effects of topical applications on the epidermis and stratum corneum. This post is financed by Vick International and is suitable for a graduate in the biological sciences; it is a two-year appointment in the first instance which may be renewable thereafter. Salary on the scale £1,689 to £2,562, depending on qualifications and experience.

Applications should take the form of a brief curriculum vitae with the names and addresses of two referees and should be sent to the Registrar, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN quoting reference no. M6/29.

Further details may be obtained from Dr R. Marks, Senior Lecturer in Dermatology.
Department of Medicine, Welsh National
School of Medicine, Heath Park, Cardiff. (2162)

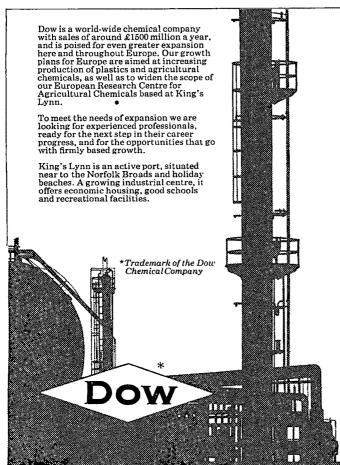

#### UNIVERSITY COLLEGE **GALWAY**

#### SENIOR TECHNICIAN

Applications are invited for the post of senior technician in the Department of Microbiology from persons holding the Advanced Certificate of City and Guilds, A.I.M.L.T., H.N.C., Diploma of Medical Laboratory Sciences, Technicians Diploma of the Department of Education or equivalent.

Applications giving details of qualifications, experience and the names of two referees to the Professor, Department of Microbiology, University College, Galway.

(2151)

### Registration/ Toxicology Assistant

to join our recently formed and rapidly expanding Agricultural Research Division at King's Lynn. The Assistant, male or female, will prepare submissions for product registration, maintain central registration and toxicological files, and liaise with contract research laboratories and field scientific personnel throughout Europe, the Middle East, and Africa. This is an important appointment demanding a graduate with a good degree in Biological Sciences, Veterinary Surgery, Pharmacology or Pharmacy.

Post-graduate experience should preferably have been concerned with the development of agricultural pesticides and/ or animal health products especially with government registration. Fluency in written and spoken English is obviously essential, and a knowledge of other European languages, especially German and Italian, would be an

An attractive starting salary will be paid and benefits include contributory pension scheme, BUPA membership and comprehensive relocation allowance. Career development prospects are excellent within the European Division.

Please write for an application form, quoting reference U.194. to:

Geoffrey J. Webb, Personnel Manager, Dow Chemical Company Limited, King's Lynn, Norfolk.

(2142)

#### ZOOLOGICAL SOCIETY OF LONDON

NUFFIELD INSTITUTE OF COMPARATIVE MEDICINE

#### LIPID BIOCHEMIST

with postdoctoral experience for two year experimental study on foetal and neonate brain development. Salary up to £2,970 according to experience; F.S.S.U. benefits. Curriculum vitae to Assistant Establishment Officer, Zoological Society of London. Regent's Park, London, NW1 4RY.

#### UNIVERSITY OF GLASGOW RESEARCH ASSISTANT

Applications are invited for the post of research assistant in the department of Cell Biology to study the nitrate reductase of free-living and symbiotic root nodule bacteria. Minimum qualifications for the post are a degree, or the equivalent, together with some experience of biochemical and/or microbiological techniques.

The work is supported by the Agricultural Research Council and the appointment is for two years in the first instance. Salary will depend on qualifications and experience but is likely to be over £2,000 plus F.S.S.U. The post is available from December 30, 1974.

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to Dr R. M. Daniel, Department of Cell Biology, University of Glasgow, Glasgow G11 6NU.

In reply please quote Ref. No. 3595M (2163)

#### UNIVERSITY OF SYDNEY LECTURESHIP IN MICROBIOLOGY

The appointee will assist in teaching Microbiology courses, supervise student research projects and undertake research in conjunction with one of the research groups studying: Microbial treatment and recycling of industrial wastes including pollution controls of water ways; bioassay and degradation of herbicides and pesticides, all aspects of biological nitrogen fixation.

pects of biological nitrogen fixation.

Candidates should have good knowledge of the whole field of basic Microbiology and be able to teach in most areas of Microbiology to Science, Agriculture, Marine Science and Pharmacy students. A higher degree or equivalent with teaching and research experience, will be given preference. Administrative and industrial experience will also be taken into consideration.

The position advertised is permanent and may be filled for three years in the first instance with possibility of permanency after that time, or in certain cases return faires.

Salary range: \$A9,002 to \$A12,352 p.a.

Salary range: \$A9,002 to \$A12,352 p.a. Enquiries to Professor Y. T. Tchan in the

Applications including curriculum vitae, list of publications and names of three referees, by January 15, 1975, to the Acting Registrar, University of Sydney, New South Wales, 2006, Australia. Information about conditions of appointment and application procedure available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, (2155)

#### ROYAL POSTGRADUATE MEDICAL SCHOOL STUDENT/JUNIOR TECHNICIAN

required in the Immunoassay Laboratory of Department of Medicine for work involving radioimmunoassays of thyroid hormones in various endocrine disorders. Minimum qualifications. GCE "O" level passes in English. Mathematics and 2 Science subjects. Salary on scale £1,107 to £1,848 per annum plus threshold payment.

Applications to the Personnel Officer (743 2030 Ext 93), R.P.M.S., Hammersmith Hasnital, DuCane Road, London W12 0HS, quoting ref. no. 2/490, (2170)

#### THE POLYTECHNIC OF NORTH LONDON

Holloway Road, London, N7 8DB

#### Research Assistantship in Genetics

Applications are invited from graduates with good honours degrees for the post of Research Assistant, to work under the super-vision of Dr C. R. Bantock on the cyto-genetics or population genetics of gastropods. The successful applicant will be expected to register for a higher degree.

Salary scale: £1,544 by £55 to £1,654.

Apply in writing, giving qualifications, experience and the names of two referees to the Head of the Department of Biology & Geology, The Polytechnic of North London, Holloway Road, N7 8DB.

#### THE COUNCIL FOR SCIENCE AND SOCIETY

invites applications for the post of ASSISTANT SECRETARY, organising Working Parties and Conferences. A knowledge of some branch of science, technology or medicine would be useful, but not essential. #### UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

#### TEMPORARY LECTURESHIP IN **GENETICS**

A temporary Lectureship in Genetics for one year, with possible extension for a second year, is immediately available.

Teaching responsibilities will be primarily for a second year class, and will cover aspects of Metazoan Genetics.

the research interests of the associated group is in the developmental genetics of Drosophilia, including Embryology and cell culture, and good facilities are available. Candidates with other research interests will also be considered. Appointment will be made on the Lecturer scale £2,118 to £4,896 per annum plus threshold payments, as soon as possible. The research interests of the associated

Application forms may be obtained from the Secretary of Science, Science Office (E), University of Sussex, Falmer, Brighton BNI 9RH. (2165)

#### UNIVERSITY OF THE WITWATERSRAND

Johannesburg, South Africa DEPARTMENT OF GEOLOGY

Applications are invited for the following posts:-SENIOR LECTURESHIP IN PETROLOGY

Applicants should have substantial research experience in the field of igneous and/or metamorphic petrology, a familiarity with experimental petrologic techniques, and a Ph.D. or equivalent qualification.

petrologic techniques, and a Ph.D. or equivalent qualification.

SENIOR LECTURESHIP IN ENGINEERING GEOLOGY AND GEOTECHNICS

Applicants should state clearly their experience in Application of geomathematics to the study of the properties of geological materials.

Starting salaries for these posts will be determined according to qualifications and experience within the following ranges:

Senior Lecturer: R8,460 to R11,250 (annual increments not less than R360); Lecturer: R6,300 to R9,180 (annual increments R360).

R1.00=£0.62=\$US1.44.

Intending applicants may obtain the information circular relating to these posts, and outlining the attractive fringe benefits, from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa. Applications giving full career and porsonal details, should be submitted not later than January 30, 1975. UK applicants may obtain the information sheet relating to this post from the London Representative. University of the Witwatersrand, 278 High Holborn, London W.C.1.

#### **HEAD: DIVISION OF** VIRAL PRODUCTS

NATIONAL INSTITUTE FOR BIOLOGICAL STANDARDS AND CONTROL

Applications are invited for the post of Head of the Division of Viral products in the above Institute. The primary object of the Institute is the control, in relation to the Medicines Act 1968, of biological substances used in human medicine. The Division, which at present has a scientific staff of twelve, is responsible for the control and standardisation of viral products, activities which are well supported by research work. Salary would be according to age, qualifications and experience within the range of £6,105 to £8,121.

The Institute at present is one of the establishments of the Medical Research Council, but it is expected that, as a result of impending legislation, the management will at some time in the near future be transferred to a new employing authority, viz. the National Biological Standards

Applications should be sent to the Director, National Institute for Biological Standards and Control, Holly Hill, Hampstead, London NW3 6RB by the end of January 1975, and should include the applicant's curriculum vitae, list of publications and the names of three referees. (2121)

### information scientist

#### crop protection research

Have you a degree in chemistry or a biological science?

Could you accept responsibility for all the information needs of one of our research areas-research chemicals, biological data, patents, other literature, competitors' products etc?

Can you communicate effectively with technical people at all levels and in several disciplines?

Can you work on your own initiative with enthusiasm and determination?

Could you take advantage of and help improve our computerised information services?

Are you aged 23-30?

If you fit these requirements and have preferably had some experience of information work in and R & D environment, we would like to hear from you.

Attractive salary and fringe benefits include Profit sharing Scheme and Pension Fund. Assistance with house purchase may be applicable.

lealott's Hill Research Station is situated on a pleasant farm estate between Bracknell and Maidenhead.

#### POSTDOCTORAL FELLOWSHIP

Applications are invited for above post supported by the Medical Research Council. Appointment is for two years with possible extension for third year. Salary in range £2,247 to £2,580 plus threshold payments.

Applicants who hold a Ph.D. in Organic Chemistry or Biochemistry are expected to take part in work in progress in the Unit concerned with the identification and synthesis of the endogenous compound with morphine-like actions recently discovered in the central nervous system. Facilities will be provided in the Unit and in the Department of Chemistry.

Further particulars from the Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by December 22, 1974.

(2096)

## POSTDOCTORAL FELLOWSHIPS IN ASTRONOMY AND ASTROPHYSICS AT CALTECH

ASTRONOMY AND ASTROPHYSICS AT CALTECH

The California Institute of Technology invites applications for Postdoctoral fellowships in astronomy and astrophysics. Awards, beginning in summer or autumn 1975, will normally be for one year with likely renewal for a second year. Caltech is active in observational astronomy (radio, millimeter, infrared, optical, X-ray, and cosmic ray; solar, planetary, interplanetary, stellar, interstellar, and extragalactic), laboratory astrophysics (nuclear, atomic, and chemical), and theoretical astrophysics (with emphasis on cosmology, galaxies, stars, coherent emission processes, and nuclear and relativestic astrophysics). It is expected that postdoctoral fellowships will be available in the fields of (1) radio astronomy, (2) X-ray astronomy, (3) cosmic ray physics, (4) solar physics, (5) lunar science, (6) planetary science, (7) nuclear astrophysics, and (9) theoretical astrophysics.

Research capabilities include: the radio facilities of the Owens Valley Radio Observatory including conventional and VLB interferometry and spectrometry; new millimeter-wave antennas now under design and construction; the optical and infrared facilities of the Hale Observatory; rocket-borne X-ray telescopes; airplane-borne infrared telescopes; balloon- and satellite-borne cosmic-ray telescopes; balloon- and satellite-borne cosmic-ray telescopes; accelerators and facil-ties for measuring nuclear and agomic reaction rates and cross sections; laboratories for isotopic analyses of meteorites and lunar rocks; an IBM 370/158 computer; a PDP-10 computer; and a terminal into a CDC-7600 computer; and a terminal into a CDC-7600 computer.

Caltech is an Equal Opportunity Employer with an Affirmative Action Program. We encourage applications from women and members of minority

applications from women and members of minority groups.

Applicants should write for application forms to Professor Maarten Schmidt. Executive Officer for Astronomy, California Institute of Technology, Pasadena, California 91125. All application materials should reach the California Institute before February 15, 1975. (2099)

#### UNIVERSITY OF YORK DEPARTMENT OF BIOLOGY

DEPARTMENT OF BIOLOGY

A Research Studentship funded by the Multiple Sclerosis Society is available immediately for work which can lead to a higher degree, on the association and interaction between different cell compartments and the myelin sheath on central nerve tissue in health and disease. Applicants should have a good first degree in Biochemistry, Physiology or a Biological Science and applications together with the names and addresses of two referees (or request for further information) should be sent to Dr M. G. Rumsby, Department of Biology, University of York, York YO1 5DD, as soon as possible.

(2115)

#### **NEWCASTLE-UPON-TYNE** WILFRED HALL FELLOWSHIP

Applications are invited for the Wilfred Hall Fellowship (tenable for two years from October 1, 1975) from persons who have shown themselves able to carry out original research in the field of Pure Science. The value of the Fellowship is £2,118 in the first year and £2,247 in the second

year.
Further particulars and application forms (which must be returned by January 15, 1975) may be obtained from the Registrar, University of Newcasife upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, NEI 7RU. (2125)

#### UNIVERSITY OF SUSSEX RESEARCH FELLOW IN SCHOOL OF **BIOLOGICAL SCIENCES**

Applications are invited for a postdoctoral research fellowship involving studies of electrophysiological and bicchemical changes in the membrane of Acetabularia during cap regeneration. Training in electrophysiology is required, preferably with some biochemical experience as well. The appointment, supported by the S.R.C., is in the Development Biology Group under Dr Goodwin and is tenable for three years from October 1, 1974 or three years from October 1, 1974 or thereafter with a salary on the scale £2,118 to £2,412, plus F.S.S.U. benefits and threshold payments.

Applications with names of two referees should be sent as soon as possible to Dr B. C. Goodwin, School

of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG. (2117)

#### UNIVERSITY OF EDINBURGH RESEARCH FELLOW/ASSOCIATE IN CLINICAL PHARMACOLOGY

Applications are invited from graduate chemists, biochemists, pharmacists or pharmacologists for the above post in the University Department of Therapeutics, The Royal Infirmary, Edinburgh. The successful applicant will be working with clinical pharmacologists on studies of drug metabolism in relation to toxicity, and experience in an sufficient chemistry is desirable.

The post is supported by a grant and is tenable for a maximum period of three years. Salary on the scale £2.118 to £3.285, according to qualifications and experience.

the scale 12.18 to 13.725, according to qualifica-tions and experience.

Applications, giving the names of two referees, should be sent to Dr. L. F. Prescott, University Department of Therapeutics, The Royal Infirmary, Edinburgh EH3 9YW, not later than December 16, 1974. Please quote reference 5054. (2118)

#### UNIVERSITY OF SOUTHAMPTON POSTDOCTORAL RESEARCH **FELLOWSHIP**

FELLOWSHIP

Applications are invited for an S.R.C. Postdoctoral Fellowship in Inorganic Chemistry to investigate the reactions of ligands coordinated to
metals of the platinum and adjacent groups.
Applicants should have had experience in synthetic
inorganic chemistry but synthetic organic chemists
will also be considered.

The appointment will be tenable for one year
and may commence at any time between January
and October 1975. The salary will be in the range
£2,118 to £2,247 per annum (plus threshold payments) and will include F.S.S.U. benefits. Applications, giving curriculum vitae, the names of two
referees, a list of publications and reprints (if
available) should be addressed to Dr George
Rouschias, Department of Chemistry, The University, Southampton SO9 5NH. (2126)

## ICI Postdoctoral Research Fellowships

Applications are invited under the terms of the ICI scheme for the award of postdoctoral research Fellowships. Awards for the academic year 1975/6 will be the last made under this scheme, which will end with the completion in 1977 of projects started in October 1975. Fellowships may be held at the universities listed below. Additionally, up to five of the Fellowships may be held at appropriate European research centres.

University of Aberdeen University of Aston in Birmingham University of Bath The Queen's University of Belfast University of Birmingham University of Bradford University of Bristol **Brunel University** University of Cambridge The City University Cranfield Institute of Technology University of Dublin, Trinity College University of Dundee University of Durham University of East Anglia University of Edinburgh University of Essex University of Exeter University of Glasgow

Heriot-Watt University University of Hull The National University of Ireland (Dublin, Cork, Galway) University of Keele University of Kent at Canterbury University of Lancaster University of Leeds University of Leicester University of Liverpool University of London Loughborough University of Technology University of Manchester (including University of Manchester Institute of Science and Technology) University of Newcastle upon Tyne University of Nottingham

The Open University University of Oxford University of Reading University of St. Andrews University of Salford University of Sheffield University of Southampton University of Stirling University of Strathclyde University of Surrey University of Sussex University of Ulster University of Wales (Aberystwyth, Bangor, Cardiff, Swansea, University of Wales Institute of Science and Technology) University of Warwick University of York

The Fellowships, tenable for two years, can be held in any field relevant to ICI's own research interests: this includes many branches of chemistry, physics, the biological sciences, applied mathematics, engineering, and technology. For the guidance of the universities and intending candidates an exemplary list of research topics is available. Candidates should not be more than 28 years of age on taking up their awards, and must hold the Ph.D. degree or have equivalent research experience. Successful candidates will be expected to commence their Fellowships on 1st October 1975.

The stipend will depend upon age and experience but will generally be within the range £2,100-£2,700 per annum (subject to review), together with FSSU benefits. In the case of Fellows working at a European research centre an appropriate adjustment will, if necessary, be made to cover differences in the cost of living, and a contribution will be made towards travelling expenses.

Forms of application may be obtained from the Registrar/Secretary of the university at which the candidate wishes to pursue his

research (except in the case of London University, where enquiries should be directed to the Academic Registrar), and must be returned duly completed by 30th January, 1975. Candidates desiring to work in Europe (and only those candidates) should apply to Dr. D. C. Moore, Research and Development Department (Academic Liaison), Thames House North, Millbank, London SW1P 4QG. Candidates need apply to only one university, but may apply to not more than three if they so wish. In the case of multiple applications, separate forms must be completed in respect of each university. Among other information, candidates will be required to submit a brief curriculum vitae, a clear summary of the research programme proposed, and the names of two referees. Other things being equal, preference will be given to candidates proposing to carry out their research at institutions other than that from which they make application.

The final choice of candidates will be made by a National Selection Committee, comprising representatives of the universities and of ICI

## Research **Fellowships**

at Continental Universities Applications are invited for awards by the CIBA-GEIGY Fellowship Trust for the academic year 1975-76.

Two classes of award will be made as follows:-

CIBA-GEIGY Fellowships

CIBA-GEIGY Fellowships are offered to graduates of universities of the United Kingdom and the Republic of Ireland for research into chemistry, biochemistry, chemical technology including chemical engineering, and biology, particularly in its relation to chemistry, at an agreed university including a technological university on the continent of Europe.

Qualifications recent first degree university graduates normally resident in the UK who intend to undergo training in research for a doctorate or other higher degree at an agreed European university including a European technological university.

Duration of the award the minimum required by the university regulations subject to satisfactory progress, with the possibility of an extension for an additional year.

Scale of awards £1,900 per annum (£2,200 per annum if married) plus travelling expenses.

The candidate should not be in receipt of any other award.

Senior CIBA-GEIGY Fellowships

Senior CIBA-GEIGY Fellowships are offered to lecturers, senior lecturers, readers or those holding comparable positions at United Kingdom or Republic of Ireland universities who are also graduates of these universities and wish to undertake special study at an agreed continental European university including a European technological university.

Duration of the award minimum period of six months and up to two years.

Scale of awards £5,000 per annum plus travelling

Further details and application forms, which should be submitted before 31 January 1975, can be obtained from The Secretary, The CIBA-GEIGY Fellowship Trust, 30 Buckingham Gate, London SW1E 6LH.

(2110)

#### UNIVERSITY OF WARWICK POSTDOCTORAL RESEARCH FELLOW IN MOLECULAR **BEAM SCATTERING**

Applications are invited for an S.R.C. Post-doctoral Research Fellowship in the Department of Molecular Sciences to work on the investigation of four centre ion-molecule reactions. This will include experimental work using an existing crossed molecular beam apparatus at the Thorngon Research Centre and the calculation of potential energy surfaces and scattering calculations. The applicant should have experience in high vacuum work and preferably in molecular beams. The post is available immediately and will be for one year in the first instance with the possibility of renewal. Starting salary will be in the range £2,118 to £2,580 p.a. plus threshold, with F.S.S.U. benefits. Application forms and further particulars may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL, to whom applications should be sent as soon as possible. Please quote Ref. No: 17/A/74.

#### POSTDOCTORAL FELLOW

required for work on interaction of carcinogens with nucleic acids, starting early 1975 for 1-2 years. Stipendium approx. 1450 DM net per

Applications to Dr P. Kleihues, Max-Planck-Institut für Hirnforschung, 5 Cologne 91, W. (2153)

#### UNIVERSITY OF LEEDS

#### DEPARTMENT OF GENETICS

Applications are invited for a Research Studentship in the Department of Genetics. The successful applicant will be required to undertake studies on detection of heterozygotes, and on prenatal diagnosis, in Duchenne muscular dystrophy using isoenzymes of creatine phosphokinase and potassium conductance of cells.

Please apply to Dr M. Crawford, Department of Genetics, University of Leeds, Leeds LS2 9JT, by December 16, 1974. (2139)

#### UNIVERSITY OF ABERDEEN POSTDOCTORAL RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for above post to determine the primary structure of phospho-glycerate mutase and other glycolytic enzymes. The project is supported by the M.R.C. and is for a period of up to three years. The post is a collaborative one with the X-ray crystallography group at the University of Bristol who have determined the tertiary structure of the mutase at 3.5A resolution. Salary within range £2,118 to £2.412 per annum (plus threshold payments).

Further particulars from the Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged as soon as possible

#### PORTSMOUTH AND KINGSTON **POLYTECHNICS**

DEPARTMENT OF GEOLOGY

Applications are invited from graduates, for TWO Ministry of Overseas Development Studentships (£890 p.a.), one at each institution, starting immediately, for a period of three years, to carry out Ph.D. research as part of an investigation into the geology and mineral resources of the igneous ring-complexes of Sudan under the Direction of Dr J. R. Vail, Head of Geology Department, Portsmouth Polytechnic and Dr D. C. Almond, Senior Lecturer, Kingston Polytechnic.

Two periods in Sudan will be involved so the ability to carry out independent field work in the desert is essential. A knowledge of Arabic and ability to drive would be use-

Applications to and further particulars from Dr J. R. Vail, Department of Geology, Portsmouth Polytechnic, Burnaby Road, Portsmouth, PO1 3QL by January 6, 1975. (2161)

#### AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

#### RESEARCH FELLOW DEPARTMENT OF BIOCHEMISTRY

The Research Fellow will collaborate with an existing research group in the Department in work in one of the following areas: Protein chemistry, with particular reference to the isolation and characterisation of membrane proteins from normal and mutant bacteria; Biochemical genetics of bacterial oxidative phosphorylation; Enzyme reactions mechanisms with particular reference to allosteric enzymes.

Further details of the research work may be obtained from Professor F. Gibson, John Curtin School of Medical Research, Australian National University, Canberra

Closing date: March 1, 1975.

#### RESEARCH SCHOOL OF PHYSICAL SCIENCES

#### FELLOW/SENIOR RESEARCH FELLOW/RESEARCH FELLOW IN COLLOID SCIENCE, BIOPHYSICS

Appointment would be in the Department of Applied Mathematics, Institute of Advanced Studies, which works in Colloid and Interface Science with a bias towards membrane biophysics (Professor B. W. Ninham) and in Vision Research and Optical Communications (Dr A. W. Snyder), It has close working links with the Department of Neurobiology (Professor G. A. Horridge) and the Department of Theoretical Physics and works also in Liquid State Physics. Enquiries are especially invited from people interested in the Colloid field and/or Polymer Science. The Department would particularly welcome a person with some knowledge of or an interest in membrane biology, and it is expected that some opportunity to do experimental work may arise if desirable. Closing date: January 31, 1975.

Closing date: January 31, 1975.

SALARIES (under review): Salary on appointment will be in accordance with qualifications and experience within the ranges: Fellow \$A10,771 to \$A14,704 p.a.; Senior Research Fellow \$A13,163 to \$A15,548 p.a.; Research Fellow \$A9,002 to \$A12,269 p.a.; current exchange rates are approximately \$A1: 56NP: \$US 1.31.

OTHER CONDITIONS—Tenure: Fellow for five years in the first instance with possibility of extension to retiring age; Senior Research Fellow and Research Fellow normally for three years in the first instance with possibility of extension to a maximum of five years.

Reasonable travel expenses are paid and assistance with housing is given for an appointee from outside Canberra. Superannuation is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Applis.) 36 Gordon Square, London WC1H 0PF, for further particulars before applying. (2154)

#### THE ROYAL SOCIETY WARREN RESEARCH FUND COMMITTEE

The Warren Research Fund Committee of the Royal Society invites applications for a WARREN RESEARCH FELLOWSHIP. In accordance with the terms of the Trust, this appointment may be for scientific research in metallurgy, engineering, physics or chemistry or for the use or application of such research or its results in or for industry and industrial development.

The Fellowship will be tenable in any university, industrial research laboratory or research institution or at any other place in the United Kingdom subject to the approval of the Committee. Candidates should supply the usual personal details and two referees. Testimonials will not be considered. The subject of the proposed research, and the place at which it would be carried out, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment is tenable for four years in the first instance from October 1, 1975 and may be renewed for further periods at the discretion of the Committee. The scale of stipend will be either £5,097 by £180 to £5,817 per annum or £3,870 by £177 to £4,578 per annum, both with threshold payments in addition and appropriate superannuation benefits.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and should be received not later than February 14 1975. (2116)

#### THE UNIVERSITY OF LEEDS

#### Department of Biochemistry

Applications are invited for a POST-DOCTORAL RESEARCH FELLOWSHIP for the study of muscle membranes in dystrophic animals. This work will involve the purification and analysis of the components present in these membranes. Preference will be given to biochemists or chemists with some experience in protein chemistry and/or membrane biochemistry.

The appointment will be for one year in the first instance, renewable for a further two years, and is financed by a grant from two years, and is financed by a grant from the Muscular Dystrophy Group of Great Britain. Salary, according to age and ex-perience, will be in the range of £2,118 to £2,757 plus F.S.S.U. Threshold supplements are additional to this scale. The appointment can be made as soon as convenient.

Enquiries or applications (with curriculum vitae and the names of two referees) should be sent as soon as possible to Dr C. F. Louis, Department of Biochemistry; 9 Hyde Terrace, Leeds LS2 9LS (Tel. 0532 36171).

(2120)

#### LECTURES AND COURSES

THE FIFTH SUMMER COURSE IN TISSUE CULTURE

April 28 to May 23, 1975 UNIVERSITY OF SASKATCHEWAN DEPARTMENT OF ANATOMY AND EXTENSION DIVISION

The course will introduce basic principles of mammalian and plant tissue cultures. It will include laboratory work, demonstrations, seminars, informal discussions and lectures. It is intended primarily for graduate students and scientists. For more information write or telephone Dr S. Fedoroff,
Department of Anatomy, University of Saskatchewan, Saskatoon, Sask. S7N 0W0, Canada.
Telephone: 306-343 2661. (2167)

#### UNIVERSITY COLLEGE LONDON

The College will again offer a one-year advanced course leading to the University of London

#### M.Sc. IN CONSERVATION

Applicants will normally be expected to have obtained a first or second class honours degree in Agriculture, Biology, Botany, Forestry, Geography, Geology, Zoology or other appropriate subjects. The course is constantly adjusted to new needs in conservation and is recognised for the tenure of N.E.R.C. Advanced Course Studentships.

The course begins in September 1975, and runs for one calendar year. Closing date for applications, January 15. Particulars and application forms from Registrar, University College London, Gower St, WCIE 6BT. (2168)

#### FOR SALE AND WANTED

#### **BIOLOGICAL REVIEWS**

#### Availability of Back Numbers

All parts of Biological Reviews are available from the Cambridge Philosophical Society, Bene't Street, Cambridge, England, at the following prices:—

Vols 1-49 £8 per volume (£2.60 per part) Vol. 50- £10 per volume (£3 per part)

The following discounts are allowed:-

Orders of 2 to 5 volumes 5 per cent. " 6 to 10 10 per cent. ,, 15 per cent. " 11 to 20 ,, over 20 25 per cent.

These discounts apply until March 1976.

## **XEROX**

University Microfilms Limited, St. John's Road, Tylers Green, High Wycombe, Buckinghamshire, England, HP10 8HR a XEROX company

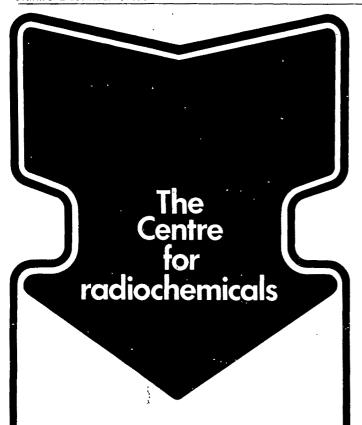

University Microfilms offer the convenient way of acquiring the most authoritative collection of science history — **Nature** backfiles in microform.

Since 1869 **Nature** has been investigating and recording the developing role of science in society, building into an unique collection of scientific thought.

As the leading international journal of the Physical and Biological Sciences **Nature** was recently voted the top international scientific journal — not surprising when it has featured the first papers on such topics as Fingerprinting, the Neutron, Synthesis of Penicillin, Structure of Haemoglobin, Sea Floor Spreading. These and many more **Nature** firsts are exclusively held by University Microfilms in microform.

We invite you to look into your periodicals library. **Nature** in microform could be the convenient way of acquiring the top scientific journal for your library — alternatively if you already subscribe to **Nature** why not complete your hard copy holdings now — in microform.

## **BORIC ACID GELS**

### for the column chromatographic separation of sugars and nucleic acids

18,445-4 Boric acid gel, particle size 0.1 - 0.4mm. 30ml \$75.00

18,518-3 Boric acid gel, particle size <0.1mm. 30ml \$150.00 Boric Acid Gels are cross-linked polymers insoluble in water and organic solvents. They are prepared by the cross-linking copolymerization of dihydroxyborylanilino-substituted methacrylic acid with 1,4-butanediol dimethacrylate.

These gels serve as useful packing material for the column chromatographic separation of mixtures whose components form complexes of varying stability with boric acid. Complex formation is dependent upon pH and molarity of the buffer used.

The separation of mono- and oligosaccharides,<sup>2</sup> ribonucleosides-deoxyribonucleosides,<sup>1</sup> oligonucleotides<sup>3</sup> and t-RNA has been reported.

Boric Acid Gels may be used for preparative as well as analytical procedures, and are available in two porosities.

#### Guide to authors

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. There is a limit of 300 words.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible, exp (a) is preferred to e if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions.

References are indicated by superscripts in the text. See any contemporary Nature for style, but note:

- (i) To refer to several references by the same author at once, only one reference number need be given.
  - (ii) Cite first and last pages.

Abbreviations should follow the World List of Scientific Periodicals, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-bepublished volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. We are always glad to see artwork for possible use on the cover, whether or not it is associated with a manuscript, but cannot guarantee the return of material.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

A fuller guide appeared in Nature (246, 238; 1973).

Oral contraceptive for men—M. Briggs and M. Briggs  LSD as an agonist of dopamine receptors in the striatum—L. Pieri, M. Pieri and W. Haefely	585 586
LSD as an agonist and antagonist at central dopamine receptors—K. von Hungen, S. Roberts and D. F. Hill	588
The activity of membrane bound enzymes in muscular dystrophic chicks— S. B. Rodan, R. L. Hintz, R. I. Sha'afi and G. A. Rodan	589

Answers to Christmas Quiz	622

Nature for December 20 will be a double issue, and the next issue after that will appear on January 3 1975.

### Paying the piper

THE perks of working in the Nature office are not extensive. No doubt if the journal were dedicated to the evaluation of stereo equipment or gourmet meals or travel to the tropics we would not lack material benefits, but reporting on advances in science and on science policy hardly leads to obvious free handouts. Can you imagine the Science Research Council's report being distributed with a modest fusion reactor or an 'autonomous house' to keep the press happy? Of course we get the occasional lunch, the odd trip abroad and even an executive jet flight now and then to help us see things in an objective light. We also get an agreeable pile of diaries and calendars (and if Ciba-Geigy read this I'd like them to know how I've enjoyed their calendar of fully dressed high class girls and how I hope I'll get another one this Christmas). And the other day a tiny crate containing a bottle of champagne to help me join in celebrating the launching of a brand new film on embryology the makers of which I can't plug in these columns. But the most interesting perk I've yet had came a few evenings ago.

Bayer AG Leverkusen makes drugs and like every other large company these days a million and one other things also. It also has a symphony orchestra conducted by Rainer Koch and comprised entirely of its own employees. That is unusual, you may say, but not unique; companies keep all sorts of things besides football teams these days. Aren't there famous bands such as Black Dyke Mills Band and Foden Motor Works Band? (I can remember advertisements in the local paper, "Stanton Iron Works requires a tenor euphonium player; office job will be found"). What's new about the Bayer Philharmonic?

I cannot claim to be a music critic, although I do reckon to know a fair bit about orchestras, and not through regurgitating comments from record magazines. Nevertheless it was clear that the Bayer Philharmonic would have stood comparison with the best of amateur orchestras anywhere in the world. For its concert in the Fairfield Hall, Croydon, the company had invited along staff, customers, business associates and, no doubt, rivals ("got anything like that in your company, eh?"). The orchestra started with Vaughan Williams's "The Explorer", film music of the 1950s and a rarity indeed in English concert programmes. Nice as it was as a gesture it didn't really come off. Vaughan' Williams is so English and has to be appreciated in the context of green fields, sheep and country pubs; there is something intangibly incongruous in eighty German drug company employees in dinner jackets trying to make the folk songs sing. But enough chauvinism; there was little to fault elsewhere in the programme.

Dinorah Varsi joined the orchestra to perform Chopin's somewhat over-inflated piano concerto in E minor. The orchestra was more in its element here and

it was only the occasional ability all amateur orchestras have to make the piano sound slightly out of tune which detracted from a fine performance. The orchestra concluded the evening with an excellent rendering of Brahms's First Symphony, in which the only weakness of substance was the inability of the woodwind, particularly clarinet and oboe, to make much impression over the top of a fine body of strings.

Now what is the moral of all this, for moral there has to be, even in a Christmas issue? Not that it must take a great deal of 'spare time' to drill so precise a band. Not even that you should go out and buy Bayer products to keep the orchestra in business. Rather that it is a much more intelligent form of patronage of the arts than most companies indulge in at present.

Sponsorship and patronage is under much discussion, because in a period of financial gloom the first thing a business does is economise on its peripherals. There is an obvious tendency to regard sponsorship as advertising and thus to seek to attach the company's name to the best known events both in art and sport. In the short run this probably does little harm and a fair bit of good in keeping admission prices down. But in the long run anything that tends to centralise and to emphasise the cult of the excellent at the expense of personal participation is bad. It is good to know that various London symphony orchestras, theatres and operas are being supported by big business but it would be better to know that big business was equally among the grassroots, raising the levels of competence and enthusiasm of amateurs and young professionals in Scunthorpe, Swansea and Kilmarnock. With modest help, perhaps most intelligently supplemented by the provision of professionals to coach or even write for them, such groups can clearly flourish, and what's more young professionals can be encouraged. It may even have a longer lasting effect on the company image than a once-a-year mention in the programme of a London performance.

AFTER the Franco-Prussian war of 1870-71, it is well known that in many districts in France a new vegetation sprang up, evidently the result of the invasion. It was believed that this vegetation would become acclimatised. It is not so, however, L'Institut informs us; at least very few of the species introduced in this way appear likely to continue to flourish on French soil. In the departments of Loiret and Loir-et-Cher, of 163 German species, the half at least have already disappeared, and the surviving species diminish in vigour each year. Scarcely five or six species would appear to manifest any tendency to become acclimatised; these are, according to M. Nouel, Alyssum incanum, Trifolium resufinatum, Kapistrum rugosum, Melilotus sulcata, and Vulpia ligustica. On the plateau of Bellevue, where in 1871 many strange species were seen, M. Bureau has been able to find only one-Trifolum resupinatum. M. Gaudefroy also, who in 1871 and 1872 found many adventitious plants, has been able to collect only two this year-Ranunculus macrophyllus and Linum angustifelium.

Sahel drought: photo by Nick Fogden

Looking for a strategy to feed the World over the next decade, the World Food Conference put together a comprehensive action pack—but not all its elements looked easily compatible and the conference called on science and research workers to bridge the gap. Robin Sharp who has attended numerous United Nations conferences as a journalist and now heads Oxfam's Public Affairs Unit was in Rome writing for PAN, the highly successful conference newspaper.

To imagine that giant leaps for mankind could spring directly from a two-week 'talkfest' like the World Food Conference would be to misconstrue the nature and purpose of such events. Indeed it is probably better that the United States, the EEC and the OPEC countries did not come forward at that moment with the billions of dollars being asked for them, because with so much stress laid on the easy-to-grasp, short term crisis, we might all have returned home in a dangerous

state of euphoria. The temptation to call the conference a success would have risked implying that somehow it had 'solved' the problem of how the world is to feed itself in the next 10 years. And nothing could be further from the truth.

The principal function of the Rome meeting was to act as a means of harnessing all available political energy and then channelling it out to power the productive machinery of government, international agencies, research institutes and so on. This it has done and, as far as can be judged at such close range, done to measurably good effect. A momentum has been created; the job now will be to use and sustain it.

Already the dimensions of the immediate crisis are more widely known—some accomplishment in itself. The people of Africa, Asia and Latin \*America have spent about \$10,000 million in the past year to buy abroad the food they need to live. Now the money has run out, but at the end of the conference they were still short of 7.5 million tons of grain, which would cost about \$2,500 million at market prices. Over the next mine months, reckoned by average

grain consumption in the developing countries, we are talking about the food of 45 million people. And without some drastic intervention, the story over the next 10 years will be the same, with a high rate of compound interest.

Faced with disaster warnings of such magnitude, a world food strategy based on large scale, capital-intensive technological inputs was virtually irresistible: the answers had to be on the same scale as the problems. The potentially serious flaw in this approach is that it depends on how the problems are defined-and they get defined in their 'macro' aspect because that is the only way they are manageable. In fact, the 30-man Food and Agriculture Organisation (FAO) task force which drafted the conference's Action Plan had originally thought of submitting alternative strategies-one based on high technology, the other on labourintensive schemes utilising intermediate technology and fed in much closer to the grass roots. In the end they tried to blend the two together but the result was something of an oil and water mixture, with a preponderant dose of oil.

To improve the strategy's consistency. Third World delegates and others introduced many amendments underscoring their conviction that the aims of increased food production must be fitted into a pattern of integrated rural development, taking full account of social, cultural and environmental conditions. And perhaps it was because the massive macro schemes often seemed incompatible with the needs of the millions of poor rural workers that the final conference document laid special stress on the need for more research.

In a lengthy resolution from its First Committee, the conference expressed "concern at the inadequate amount of basic and particularly applied research directed to developing new agricultural technology suited to the needs of developing countries, as well as weaknesses in adaptive research, training and extension to achieve more effective transfer and utilisation of both existing and new technology . . ." There is a paucity of trained technical personnel, the resolution added, and much current research "lacks coordination and makes inadequate use of important information already available from research in ecologically comparable regions."

Among its nine proposals on research issues, the conference recommended:

- Rapid establishment of a global network of plant genetic resource centres and the extension of this to animal gentic resources.
- Intensified research by national and international institutions on the application of meteorological information to land-use and other agricultural planning, such as the development of alternative cropping strategies to suit different weather conditions.
- That the FAO/World Bank Consultative Group on International Agricultural Research (CGIAR) should study the feasibility of an international programme on the use of remote sensing techniques in agriculture, including the use of data from the Earth resources satellites.
- That extensive adaptive research programmes be developed, involving testing in farmers' fields the economic and technical viability of new technology and thereby tailoring recommendations to suit specific locations, farming situations and socio-economic conditions.
- That means be found to give the developing countries better access to research equipment and activities, including germ plasm resources.

On specific areas of research, the Action Plan pointed out that the socalled Green Revolution has so far only made a substantial impact on varieties of wheat, maize and rice. It suggested that barley and triticale—a hybrid between triticum (wheat) and secale cereals (rye) species-were other grains deserving a greater research effort, triticale in particular because of its potentially high yield, high protein content and potential for flourishing on marginal lands. Also, the plan stated, no work is at present supported at international level on oil seeds such as sunflower, safflower and rapeseed, although their oils are important in the diets of many developing countries. Similarly more work is justified on root crops such as cassava, which provide the energy requirements of perhaps 40 million people.

While accepting the need of extended research and development in these fields, less attention was given to the equal need for high-yield varieties able to survive without sophisticated inputs. For it is the cost and scarcity of these essential inputs—chemical fertiliser, diesel fuel for irrigation pumping, petrol for transport-which has suddenly made the first Green Revolution turn sour for many who committed their livelihood to it. And this, in turn, leads to wider questions which the World Food Conference made no attempt to assess. How far has the present crisis been exacerbated by existing large scale rural development projects? How much capital has gone into underused facilities which could have been used to create jobs and therefore food-buying power?

While pondering these dilemmas, there are formidable problems of a more practical kind to be dealt with. For example:

Development of land and water resources. The secretariat's programme

Botswana food programme; FAO photo

called for the improvement of 46 million hectares of existing irrigated lands, the expansion by 1985 of a further 23 million hectares under irrigated agriculture and development of 153 million hectares of new land in rainfed areas. The cost• of this programme would, however, amount to \$89,000 million, including about \$30,000 million in foreign exchange—and even before the conference began several delegations had registered their scepticism as to whether resource transfers on this scale could be realistically envisaged or fully absorbed.

Post-harvest losses. The importance of improved food storage received only a passing mention in the final resolutions but figures cited in the Action Plan illustrate the need for better facilities at all levels of distribution Postharvest losses in cereals, as a result of mildews and fungus diseases, rodents and insects, are estimated at 5 to 10% but up to 40% in exceptional cases. Losses of 30 to 40%, are common in perishable fruit and vegetables. Insects consume the most nutritious part of the grain, leading to deterioration in its calorific, protein and vitamin contents; and damaged grain absorbs moisture, encouraging the growth of harmful micro-organisms.

Nutrition. Information on food consumption patterns and on their consequences for the nutrition and health status for the majority of people in developing countries is insufficient, said the 15-joint resolution on this subject. Improved knowledge about how to prevent malnutrition through better use of available food resources, including human milk, is essential. The conference called on governments to explore the "desirability and feasibility of meeting nutrient deficiencies, through fortification of staples or other widely consumed foods, with amino acids, protein concentrates, vitamins and minerals." It also recommended the establishment of a global nutrition surveillance system to monitor, inta alia, the condition of disadvantaged groups, and an inventory by the FAO of vegetable food resources other than cereals, including roots, tubers, legumes and "also those from unconventional sources."

Now these and the many other recommendations of the Rome conference are in the hands of the United Nations, its various specialised agencies and individual governments, waiting to be implemented.

Ultimately, as the conference Secretary-General, Mr Sayed Marei, phrased it, "judgment on the success or failure of this conference is going to be made by hungry men and women in Africa or Asia, or by a hungry child..." But how long will they have to wait?

T HE REPORT of the work of Dr J. W. King and his colleagues at the Appleton Laboratory (252, 2; 1974) recalls articles contributed to *Nature* almost a century ago by William Stanley Jevons, economist and statistician, in which he sought to evidence the relation between sunspots and commercial crises (19, 33; 1878 and 19, 588; 1879).

Jevons's early education was in mathematics, chemistry and botany. He later developed an interest in, and wrote widely on, meteorology. This scientific training influenced his approach to the study of economics. In Letters and Journal of W. Stanley Jevons, edited by his wife (Macmillan, London, 1886) we read:

'He published in Waugh's Australian Almanac for 1859, "Some Data concerning the Climate of Australia and New Zealand", a paper over fifty pages in length, which is best described by his closing words: "My object has been to present in an available form such accurate numerical data as are attainable, and secondly, to group together general information as to the winds, rains, rivers, floods, the geographical features of the country, and the meteorological circumstances of this part of the globe, so as to show what remarkable problems have to be solved, and what interesting connections of cause and effect may ultimately be traced and proved.""

The significance of his method was that, translated into the context of 'political economy', it represented a new approach to the investigation of economic phenomena. In a paper read to the meeting of the British Association at Cambridge in 1862, "On the Study of Periodic Commercial Fluctuations, with five diagrams", Jevons wrote:

"It seems necessary, then, that all commercial fluctuations should be investigated according to the same scientific methods with which we are familiar in other complicated sciences, suche especially as meteorology and terrestrial magnetism."

In 1862, when this was written, Jevons was concerned with seasonal changes and not with the longer swings of the trade cycle; and his interest in meteorology had not led him to the theory of solar variation to explain these larger swings. His famous conclusions on the underlying causes of the trade cycle were advanced in two papers presented to the British Association in 1875 and 1878.

The fate of the first paper, "The Solar Period and the Price of Corn" is recounted in J. M. Keynes's Essays in Biography (Mercury Books, London, 1961):

'Thorold Rogers' "History of Agriculture and Prices in England", which

began to appear in 1866, provided Jevons with material for analysing wheat prices over a long period. The commercial crises in his own lifetime had occurred at intervals of ten or eleven years: 1825, 1836-39, 1847, 1857, 1866. Might there not be a connection between these things? "I am aware," Jevons concluded, "that speculations of this kind may seem somewhat far-fetched and finely-wrought; but financial collapses have recurred with such approach to regularity in the last fifty years, that either this or some other explanation is needed," Nevertheless he soon repented of publishing

## Sunspots and the business cycle

J. R. Sparkes, lecturer in economics at the University of Bradford, looks at the work of W. S. Jevons (below), who tried to relate sunspot activity and commercial crises a hundred years

what was no better than a bright idea. "Subsequent enquiry convinced me that my figures would not support the conclusion I derived from them, and I withdrew the paper from publication"."

But Jevons still did not regard the enquiry as worthless and encouraged to discover, after withdrawing his paper, that Sir William Herschel had tried as early as 1801, although with negative results, to explain the variation in the price of corn by the decennial variation of sunspots. Thus by 1877 he was working at the subject again and was more convinced than ever that there was some connection between sunspots and the price of corn. In a letter to Professor J. d'Aulnis de Bourouill in February 1878 he wrote, concerning the years when there were commercial crises, "The periodicity is remarkable, and the average length of the period is somewhere about 10.3 years, so nearly the same as the sunspot period that there can hardly be a doubt about the connection of cause and effect."

Jevons's ideas were spelt out in a second paper to the British Association, "The Periodicity of Commercial Crises and its Physical Explanation", and the first of two articles contributed to Nature. Although still concerned about the evidence on which his theory of crises was based, he had great confidence in its substantial truth.

Keynes, in his essay, listed the new discoveries which were his excuse for returning to his theory:

- (1) He had succeeded in carrying back the history of commercial crises at ten or eleven-year intervals almost to the beginning of the eighteenth century.
- (2) He was now advised by his astronomical friends that the solar period was not 11.1 years, as he had previously supposed, but 10.45 years, which fitted his series of commercial crises much better.
- (3) He now abandoned European harvests, the price statistics for which yielded negative results, as the intermediary through which sunspots affected business, in favour of Indian harvests, which, he argued, transmitted prosperity to Europe through the greater margin of purchasing power available to the Indian peasant for buying imported goods.

But apart from the coincidence of the periodicity of the commercial crises and the solar period, the causal link was never much stronger than a personal conviction that the decennial crises depended on meteorological variations of similar periodicity. His 1875 evidence, which depended on European harvests, was overturned in 1878 in favour of fluctuations in foreign trade resulting from cyclical crop changes in India and elsewhere. But even then the timing of the relationship was such as almost to suggest that the effect preceded its cause.

Later empirical work has largely discredited the theory that there is a link between business cycles and a 10 to 11year cycle in sunspot activity. Business cycles have recurred at shorter intervals than 10 or 11 years, and in spite of ingenious interpretations of harvest statistics over the years, it is now generally agreed that such an explanation could never completely account for the business cycle. Keynes's assessment is "Jevons's summed up as follows: notion, that meteorological phenomena play a part in harvest fluctuations and that harvest fluctuations play a part (though more important formerly than today) in the trade cycle, is not to be lightly dismissed."

## international news

As part of a desperate bid to get a grip on inflation, President Ford is proposing to prune nearly \$5,000 million from federal expenditures during the 1975 fiscal year, which has only seven more months to run. Welfare, health and veterans' benefit bear the brunt of the cuts, but biomedical research, space research and several nuclear power programmes are also in the running for some radical surgery.

Ford's proposals came in three chief parts. First, he asked Congress to take the knife to the Appropriations Bill for the Department of Health, Education and Welfare (HEW), which was then in the final stages of passage through the Congressional mill. Among the cuts Ford requested was a reduction of \$112 million in the budget for the National Institute of Health (NIH), a move which he said would reduce expenditures on new grants and contracts by 25% and cut continuation grants by 5%

Such surgery, he maintained, "could accomplished without seriously altering the momentum in biomedical research achieved by sustained and substantial growth in the National Institutes of Health in recent years", but since the NIH was hit hard by cutbacks in 1973 and received only a modest budget increase this year, few biomedical scientists will agree with that sanguine prediction. Congress, in

## **Cutting budgets** to fight inflation

by Colin Norman, Washington

any case, responded to the request by passing the HEW Appropriations Bill last week with a massive increase of \$256 million in the NIH's budget instead of a decrease of \$112 million, thereby putting the ball firmly back in Ford's court.

The Appropriations Bill would step up spending in every NIH institute, with the National Cancer Institute topping the list with a budget of \$692 million -an increase of \$164 million over last year. The National Heart and Lung Institute would also receive a massive infusion of funds, amounting to \$324 million, and the entire NIH budget would climb to \$2,090 million. The Appropriations Bill additionally provides a pot of money for biomedical training, which the Administration has been trying unsuccessfully to decrease.

Ford, it seems, has two options open if he is determined to press his case over the HEW budget. Either he can veto the Appropriations Bill to try to force Congress to reduce the amounts. or he could sign it and later propose that some of the increases be deferred until next year.

Finally, Ford is recommending that money which Congress has already allocated to some programmes be spent next year instead of this year. Among the programmes he has selected for such a stretch-out are several nuclear power projects, some space research and development, and solar and geothermal energy research supported by the National Science Foundation.

He is suggesting, for example, that \$80 million in the budget of the Atomic Energy Commission be deferred, including \$8 million earmarked for the breeder reactor, \$8 million for controlled thermonuclear fusion, \$4 million for environmental research and safety, \$6.7 million for development of hardware for the high temperature gas cooled reactor, and another \$13 million for equipment needed for the fusion programme. Although Ford maintains that the delays will have little lasting impact on the nuclear power programme, those proposals provide an important indication that the Administration may be losing some of its overriding enthusiasm for nuclear energy.

As for the space programme, Ford is requesting authority to withhold until next year some \$20 million earmarked for the joint USA-USSR docking mission. He also wants to defer expenditure of \$16 million for several space science and applications projects; and \$36 million from NASA.

THE six-year-old collaboration arrangement between the World Health Organisation (WHO) and the government of India, involving a research project on genetic control of mosquitoes, is due to expire in June next year. THE flight of Soyuz 16 (December 2-8, 1974) was specifically announced to have been a preparation for the joint Soyuz-Apollo programme scheduled for 1975. Observers of the Soviet space programme have interpreted recent Soyuz flights (including that of Soyuz 15 which somewhat coyly manoeuvred about the Salyut 3 space station, without actually effecting a link-up) as being a preparation for the joint programme.

The official purpose of the flight was described by the TASS agency as the "testing of on-board systems of the Soyuz craft, which have been modernised in accordance with the requirements of the joint flight, the carrying out of scientific and scientific-technical investigations, and also observation and photography of individual sections of the Earth's surface in order to obtain data for the solution of problems of the national economy." Leaving aside the final clause (which is included in all descriptions of Soviet

#### Preparing for that space link-up

from Vera Rich, London

space missions as a sop to the economic planners) perhaps the most interesting word in the whole release is "modernised"-which, to the student of Soviet semantics displays a refreshing honesty. At one time the word would surely have been 'adapted' and the implication would have been that in any international project it would not be the Soviet side which would have had to 'modernise' to meet the heeds of the other.

The experiments carried out by Soyuz 16 relate, in fact, both to the details of the link-up and to the requirements of the on-board systems. The life-support systems were tested and the medical checks made with a cabin pressure of 540 mm Hg, which suggests a working atmosphere rich in oxygen. Hitherto, the Soviet programme has preferred a natural atmospheric mix, so this implies something of a compromise with US standards.

Preparations for the link-up included an orbital transfer, on December 3, into a circular orbit at a height of 225 km and inclination 51.8°, described as "similar" to the one the Sovuz craft will have to adopt in the joint mission. In the course of the 32nd, 38th, and 48th orbits, the new link-up systems, "created in accordance with the requirements of the 1975 joint mission" were tested in toto and also unit by unit, the tests being monitored by cosmonauts Filipchenko and Rukavishnikov themselves, as well as by ground control. Simulated linkup tests were carried out satisfactorily.

The programme also included a number of astrophysical and biological experiments, the latter ranging from the exchange of micro-organisms to the effect of prolonged illumination on the cosmonauts.

#### Entry forbidden

SIR,—This year I had planned to attend the Ninth International Meeting of FEBS (the Federation of European Biochemical Societies) in Hungary. I am a scientist, I paid my registration fees and I even had flights and accommodation arranged; but I was barred on grounds of nationality. I am Israeli!

I suppose the word international has a different meaning in Hungary.

A PhD student at King's College, London, and a member of the British Biochemical Society, I acted in accordance with the instructions in the booklet issued by the Hungarian organisers, "... Participants from countries that do not have diplomatic relations with Hungary should apply for a visa to a General Consulate of Hungary in a European country they find most convenient", and applied for a visa from London.

Even though they had four weeks to issue the visa and in spite of a special request from Professor H. R. V. Arnstein, Secretary of FEBS, they kept me waiting until the very last moment. It was intimated that I could pick up the visa when I stopped in Vienna on my way to the conference. But when I arrived at the Embassy in Vienna, three days before the conference, I received a rude and cold reception. After keeping me waiting for half a morning, they told me I was on a "black list" and forbidden entry to Hungary.

This left me in Vienna, holding worthless train and hotel reservations, wondering about the purpose of international conferences.

I would say to all organisers that if their conferences are to be truly international, they should choose countries which foster this spirit, not, for example, Hungary.

Yours faithfully,

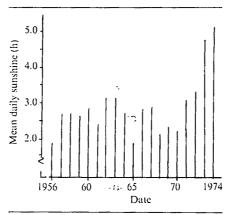

S. PELLER

King's College, London WC2, UK

#### Cameroon climate

SIR,—The catastrophic effects on humanity of the major climatological fluctuation which has caused so much concern in the Sahel zone of Africa may have overshadowed other smaller changes in the meteorological records recently obtained in adjacent areas.

Sunshine records obtained during the past 19 years in Yaounde and published by the National Meteorological Bureau of the Cameroon indicate, perhaps, a considerable shift in the distribution, and thus the total amount, of daily insolation during some agriculturally important months of the year. For example, the mean daily number of sunshine hours for July in the years 1959–74 is illustrated in the accompanying graph. The difference in the years

1973 and 1974 by comparison with the previous distribution of approximately 2 to 3 hours a day could, if confirmed by subsequent records, possibly affect the agricultural productivity of the region, which relies heavily on cocoa, a crop noted for the complex relationships between growth/yield and the shade factor.

The way in which the production of dry matter depends on energy provided by insolation is well known and if the radiation available for agricultural production has altered over a wide area, the aid programmes planned by donor agencies may need revision.

Ecole Nationale Supérieure Agronomique, BP 138, Yaounde, Cameroon

#### Asbestos and health

SIR,—In Peter J. Smith's article (October 18) the point is well made that scientists should be more concerned with the practicalities of occupational health. We think it a pity, however, that he should have selected asbestos as an example of a health problem which scientists have ignored, since more scientific effort has in fact been expended on this problem than on most other similar problems in recent years, as the literature testifies.

It is not true that "asbestosis is taking an increasing toll" in this country. The number of new cases diagnosed may be on a higher plateau now than it was in the 1950s, reflecting factory conditions long ago and the increased usage of asbestos in an uncontrolled way in, for example, insulation, but since reaching a peak of 168 in 1967 there has been no further increase. The average since then has been 139 per year. We have every confidence that stringent controls associated with the Asbestos Regulations 1969, which apply to all asbestos work, will in coming years reduce these numbers to a very low level indeed. Indeed they are intended to eliminate them altogether.

The standards associated with the controls have a scientific base for which scientists working for government departments, the Medical Research Council, the British Occupational Hygiene Society and the industry-sponsored Asbestosis Research Council deserve full credit.

Yours faithfully,

W. P. HOWARD

The Asbestos Information Committee, London W1, UK

#### Academic consultancy

SIR,—Your editorial "Academics in the Boardroom" (November 22) implies that consultancy by university staff is something to be encouraged, whereas in fact it is something to be deplored.

Professors and lecturers at universities are in receipt of a full salary for a full-time job of teaching and research, and none of them has any right to use any part of that time in consultancy to anyone, whether industrial firm or individual, or even government department or agency, for the benefit of his client or himself.

In addition no member of university staff has the right to use apparatus and facilities provided at public expense for the purposes of teaching and research, for the benefit of any organisation or for his own benefit.

It is time that the Department of Education and Science clamped down on such use of public funds to subsidise such consultancy, which has forced so many independent consultants out of business. How can any independent consultant possibly compete with the university member who does not have to pay for his equipment and facilities or premises, and may even use students as unpaid staff?

Yours faithfully, H. A. Cook

## news and views

### Excuse me, your slip isn't showing

THE inexorable motion of plates relative to each other at the Earth's surface leaves behind a magnetic record at ocean ridges where new plate is formed. Much of the early work on plate tectonics was devoted to using this record together with a knowledge of geomagnetic field reversals to measure relative plate motions. By 1970 most geophysicists were agreed on the values for inter-plate velocities, typically a few centimetres per year. The motion was obviously manifested, in fits and starts, by earthquakes. But a most important question remained—did the rate determined as an average over several million years tally with the present rate determined from the cumulative displacement of successive earthquakes? For if not, either the movement had a cyclic character, or some of the strain build-up was relieved by non-violent processes such as creep on the fault plane. The relevance of all this to earthquake prediction efforts is obvious.

In 1971, Davies and Brune (Nature phys. Sci., 229, 101-7) made a major contribution to resolving this question. The only parameter of earthquakes which has been reliably measured over the last seventy years is magnitude. The logarithm of the amplitude of the radiated surface waves (corrected for distance), or surface wave magnitude,  $M_s$ , is a rough and ready measure of the slip on the fault plane once some assumptions have been made about the dimensions of the fault surface. These assumptions, it is widely admitted, are fairly major. Davies and Brune considered the magnitudes of very large earthquakes on all plate bound-

aries and concluded that the inferred displacements over the last seventy years agreed rather well with plate tectonics predictions. Thus it was possible to deduce from their results that for most plate boundaries the part that was played by, for example, creep was certainly not a dominant one. The Mediterranean region did not immediately fit into this scheme. For one thing the tectonics of the area is immensely complex so it is not easy to talk about a small number of plate boundaries. For another, the area is not highly seismic so the data are fewer (the frequent damaging earthquakes in the region result more from the proximity of people to faults than from very high magnitude events). The area clearly warranted a special study and this has now been done by North who reports in this week's *Nature* (page 560).

He comes up with a most interesting conclusion. When similar techniques to those of Davies and Brune are applied in the Mediterranean, the movement on most plate boundaries inferred from earthquake magnitude is very much less than plate tectonics would have it. Either strain is being built up throughout most of the region (and nowhere else in the world) on various types of fault—or strain is being relieved in the Mediterranean area by other processes than major earthquakes—and again this is not happening elsewhere in the world. It is a provocative and important result and should stimulate more research both in the field and in the laboratory.

DAVID DAVIES

## Switching off symmetry breaking

The elementary particles nearly obey a number of simple and elegant symmetry rules. Many useful approximate calculations can be made by assuming that the symmetries are perfect-for instance by assuming that the decays of K° mesons are well behaved when all the particles in the decay process are regarded as travelling backwards in time (time-reversal symmetry), or by assuming that the proton and neutron have the same interactions as the lambda, sigma and xi hyperons. Recently a great deal of progress has been made in building field theories of the elementary particles, such as the unified weak and electromagnetic theories which have been supported by the discovery of 'neutral weak currents' (see Nature, 245, 119; 1973 and 250, 186; 1974). These new theories incorporate symmetry breaking as a 'spontaneous' effect, drawing on successful theories of low-energy solid-state phenomena such as superconductivity which is also caused by 'spontaneous' symmetry breaking.

When a superconductor with zero resistance is placed in a high magnetic field, above some critical strength, it reverts to being a normal conductor. The theory of this transition has been taken as a model by Salam and Strathdee (this issue of *Nature*, page 569). They show that the same kind of behaviour could occur for a number of the symmetry-breaking effects in the weak interactions of elementary particles. For instance, there may be a critical magnetic field which would turn off the time-reversal asymmetry in  $K^0$  decay. They estimate this field to be between  $10^8$  and  $10^{14}$  gauss— $10^4$  or more times what can be achieved in a practical apparatus. Another example they give is that the  $\beta$  decay of the lambda hyperon may be turned off at  $10^{18}$  gauss.

Although such field strengths may be difficult to achieve in the laboratory—partly because of the critical field effect itself in superconductivity which limits the strength of our magnets—they may already exist inside pulsars. If so, it may be possible to devise ways of detecting the effects of an absence of symmetry breaking. Another way of achieving high field densities may be through laser compression, using similar techniques to those being developed in research on thermonuclear fusion.

Even if we cannot achieve the predicted fields, they urge that experiments should be started to look for this kind of effect. Their current calculations are so model-dependent that they cannot rule out new effects at fields as low as 10<sup>6</sup> gauss.

D. J. MILLER

## Chromosomes and malignancy

ABNORMAL chromosomes are a regular feature of tumour cells. Non-transformed cells rarely show chromosomal abnormality unless obtained from developmentally defective individuals, many of whom show an increased predisposition to cancer. Altered chromosomes therefore either predispose oncogenic change or accompany it. Most cancer-producing agents cause chromosome damage, which may therefore be an important aspect of their potency for tumour induction. But the majority of such damaged cells are inviable, a few are transformed and only a proportion of these may have malignant properties. These wide ranging manifestations of the transformed state have attracted the attention of many workers seeking some explanation in terms of the accompanying chromosomal alterations.

Sachs and his group (Hitotsumachi, Rabinowitz and Sachs, Nature, 231, 511; 1971) have shown that the in vitro propagation of polyoma transformed cells may be accompanied by loss of malignant characteristics and the appearance of new groups of chromosomes which are suggested to carry suppressors of malignancy; the balance of these chromosomes in the nucleus is supposed to be an important feature of its control. Harris and his coworkers (Klein, Bregula, Weiner and Harris, J. Cell Sci., 8, 659; 1971; Weiner, Klein and Harris, J. Cell Sci., 12, 253; 1973) have fused together cells with and without malignant properties. The result of such an experiment is usually suppression of malignancy, followed by its restoration after the loss of chromosomes from the normal, non-malignant, parent. Fusing together two malignant cells however usually resulted in a malignant cell without the necessity for chromosomal loss. In certain cases the latter experiment resulted in loss of malignancy (Harris, Proc. R. Soc., B179, 1; 1971), all of which leads Harris to stress the role of individual chromosomes which carry malignancy suppressors as the important feature of its control. Both groups invoke chromosomally based factors as the essential elements, although in neither case are particular chromosomes designated as the carriers.

In this issue of *Nature* however (page 610) Codish and Paul report the reversible appearance of a specific chromosome which suppresses malignancy in a chemically induced tumour. When present in two copies, both malignancy and antigenicity are suppressed, but both are restored when only a single copy is present. The extra chromosome is thought to originate from the fusion of part of a normal number 19 mouse chromosome with an unaltered number 7. Since the normal elements of this marker chromosome are also present in the cells, it seems possible that the suppression involves a position effect following fusion of the two normal chromosome segments, although this is not suggested by the authors. There seemed to be no other consistent correlation with suppression of malignancy.

A somewhat similar mechanism, resulting in the acquisition of malignancy rather than its suppression, is suggested in the case of the now classical examples of human tumours: chronic myeloid leukaemia in which 90% of cells exhibit a loss of most of the long arm from chromosome 22 (Caspersson, Gahrton and Lindsten, Exp. Cell. Res., 63, 238; 1970) and the acquisition of a similar fragment by the number 9 chromosome (Rowley, Nature, 243, 290; 1973); and meningiomas in which there is also loss of part of the number 22 chromosome (Zankl and Zang, Humangenetik, 14, 167; 1972). Other cases of specific abnormalities include the number 14 chromosome with an additional terminal fluorescent band in tumours of some patients with Burkitt's lymphoma (Manolov and Manolova, Nature, 237, 33; 1972), and the number 13 interstitial deletion in retinoblastoma (Wilson, Towner and Fujimoto, Am. J. hum. Genet., 2, 212; 1973). Not surprisingly, some tumours seem not to exhibit specific alterations in chromosomes, but show random changes (Popescu et al. Int. J. Cancer, 14, 461; 1974) and others exhibit variability in malignancy correlated with the fluctuation in numbers of heterochromatic minute chromosomes (Shepard et al., Cytogenet. Cell Genet., 13, 279; 1974). The interest of the material described by Codish and Paul lies in the apparently clear-cut nature of the phenomenon and one hopes that they will take advantage of the cell fusion approach to analyse it in more detail.

The tendency of certain tumours to exhibit predictable alterations in certain chromosomes, whether connected with increased malignancy or its suppression, presumably reflects a number of related factors such as the probability of the alteration occurring, the viability of the altered state and the predilection of certain carcinogens for causing damage at selected sites. It may be that certain chromosomes (for example those involved in nucleolus organisation) come more frequently into contact than others thus increasing the probability of interchange.

It seems quite certain however that particular groups of chromosomes are more frequently involved in formation of the marker chromosomes typical of a cell line than are others following virus transformation by adenovirus, SV40 and herpesvirus (Gallimore, cited in McDougall, Prog. med. Virol., in the press). Chemical transformation of rat cells also results in the preferential involvement of three autosomes in marker formation (Olini and DiPaolo, J. natn. Cancer Inst., 52, 627; 1974) and two of these are regularly involved in the genesis of markers in adenovirus transformed cells (McDougall, Prog. Med. Virol., in the press). An important future task will be to establish the mechanism of this effect. For this purpose virus-transformed cells seem ideal since they permit the use of specific probes which can detect integrated viral genomes, their transcriptional and translational products at the cell level. A beginning to such work has been made by the localisation of the control of SV40 T antigen to human chromosome 7 (Croce, Girardi and Koprowski, Proc. natn. Acad. Sci, U.S.A., 70, 3617; 1973). Progress should be spectacular in view of the recent advances in analysis of the transforming genes of adenoviruses (see Rogers, Nature, 251, 668; 1974). K. W. Jones

## Arrival of the age of Rama

It is now generally accepted that the survival of the human race is threatened by twentieth century technology. Mankind must live with the uncertain hope that future imnovation will not create more dangers than it removes, and occurs rapidly enough to forestall the collapse of organised industrial society.

Speculative science fiction enthusiasts have long dreamed of preserving humanity from earthbound destruction by colonising other planets. The stunning successes of near space exploration over the last decade have moved the discussion of extraterrestrial migration out of the domain of pure fantasy into the 'light relief' area of established science. But most of the colourful accounts published assume a depressingly high level of technology, in many cases decades or even centuries ahead of our present development. It is not now at all clear that technology will ever be able to reach the level at which exotic extraterrestrial solutions, such as the colonisation of Mars, will provide for the continuation of the human species. The global crisis has apparently arrived a few decades too soon.

If there is little ground for confidence in further gigantic technological leaps in the foreseeable future, it is heartening

to learn what radical possibilities for the extraterrestrial propagation of the human race are available with present day technological, economic, social and cultural constraints. One such possibility was put forward in Nature (250, 636; 1974) and received a detailed appraisal in Physics Today (27, 32; September 1974). In an article entitled "The Colonisation of Space", Gerard K. O'Neill, a professor of physics at Princeton University, outlines a scheme for constructing small "planetoids" in space for habitation by millions of people. The structure of these artificial worlds will be familiar to all those who have read Arthur C. Clarke's novel Rendezvous with Rama. They consist of a rotating cylinder, with the inhabitants living on the inside surface at normal gravity, in a completely self-contained ecosystem. The cylinders would be lit by sunlight reflecting from mirrors through glass or plastic cellular windows. Otherwise construction would be mainly from aluminium and titanium, with power requirements more than adequately met from solar radiation using conventional steam turbine electric generators.

Cylinders could be constructed in tandem, oppositely rotating and coupled so that they may always be orientated towards the Sun. A suitable place in space to locate them would be the L<sub>4</sub> and L<sub>5</sub> Lagrange libration points of the Earth-Sun-Moon system.

At first sight, Professor O'Neill's proposals appear to suffer from all the drawbacks of traditional space colony speculation; principally, the enormous energy expenditure necessary to transport a vast mass of material by rocket from the surface of the Earth. In fact, two crucial aspects of his ideas remove this objection. First, the project is selfperpetuating. With the establishment of a small scale pilot scheme providing an adequate environment for an industrial base, components for much larger cylinders could be manufactured and assembled in situ, thus reducing the problem to that of providing only raw materials. Second, the source of raw materials is suggested to be the Moon (and eventually the asteroid belt), the low gravity and vacuum conditions of which reduce enormously the energy expenditure required to transport ore to the colony. O'Neill discusses novel mechanisms, such as a two-arm rotor, the ends of which are moving at lunar escape velocity, which would propel. pellets of lunar material at the rate of 3.250 tons per year, whilst operating at only 1,600 horse power. After a generation or two, the cylinder worlds would become entirely self-supporting-

In spite of the enormous possibilities available for this type of adventure using only current technology it is hard

to resist the impression that space Goliaths of this kind would not be economically viable. O'Neill has undertaken a cost analysis of the scheme. and claims that a kilometre-long, 10,000 population cylinder would cost about the same as the Apollo space project, thus being well within even national resources, and could be established as early as 1988. The cost of transporting 10,000 people to the colony could be met by the transportees themselves at, say, £10,000 per head. Larger cylinders would be able to pay for their own construction out of various space-based industrial products, such as high strength crystals.

Looking beyond the Solar System, there are available possible mechanisms for propagating humanity across the Galaxy. Although current rocket power can only achieve payload velocities of a few thousand miles per hour, travel time to nearby stars in the Galaxy is still only a few million years, that is, comparable with the age of the human race and a minute fraction of the life-time of most stars. Naturally, adult humans could not accompany a space capsule on such a venture, but millions of fertilised ova could easily be sent in a very small craft: The chief problems would be biological rather than mechanical. Craft such as these could then search the Galaxy for likely looking planets. One scheme might be to attempt to attract hypothetical extraterrestrial civilisations, which would then be given the responsibility of 'hatching' the nascent community. Alternatively this could be done automatically. The craft could be equipped with detailed biological and cultural information, so that the scheme would amount to a true extension of the human race rather than just putting flesh and blood on other worlds.

In the present social and economic climate, it is hard to imagine that schemes of this variety would get off the ground. The failure of space technology to provide any convincing major benefit to mankind has led to a rejection of large scale space exploration by the taxpayer. While space programmes were orientated towards 'glory trips' this was bound to happen. But against this background of muddled priorities projects such as O'Neill's are very appealing. Many direct benefits to mankind are apparent, not the least of which is a solution to overpopulation. Such projects could be undertaken as essentially a human, rather than a national venture, and provide a new perspective on the position of man in the Universe. They would also give a strong stimulus of confidence in a maligned technological system which, whether we like it or not, we can no longer do without. P. C. W. DAVIES

## A centenary in population biology...

from J. L. Harper

In 1874 Wilhelm Carl Naegeli presented a paper to the Munich Academy of Science on "the displacement of plant forms by their competitors" (Sitzb. Akad. Wiss. Munchen, 11, 109; 1874). This represented perhaps the first attempt at a serious mathematical treatment of one of the fundamental questions in population biology and arose directly from Naegeli's reading of Darwin's Origin of Species. Publication of Naegeli's paper in the mathematics/physics papers of the academy was probably partly responsible for its failure to have any impact on the development of biological thinking. The paper is summarily mentioned by Gause (The Struggle for Existence; Williams and Wilkins, Baltimore, 1934) but otherwise seems to have been ignored in the development of a science that gained no significant momentum until 50 years later. Remarkably, this early essay in modelling of populations concentrated on problems in plant ecology whereas virtually all the subsequent development of experiment and theory in population biology has been concerned with animals.

Naegeli considered the consequences of introducing a new form into an already fully stocked population of plants. This contrasts with later developed theory which was usually concerned with simultaneous colonisation of an unoccupied habitat. He suggested that in a locality the average number of plants (z) of any type reveals its relative strength against all other competitors. The average age of the individual plants (d) and the annual replacement by young plants (e) together determine (z), both (d) and (e) depending on heredity and environmental influences. He recognised that when two species differ markedly in size, their numbers may be an inadequate description of relative abundance and the relative space occupied by the species might then be a better measure, but he avoided this problem by comparing pairs of closely related species. His ideal model was of a community of only two such species but "this very simple case . . . seldom occurs in nature". The seemingly more complicated but analogous case in which two closely related taxa live among vegetation composed entirely of other kinds of plants could be studied if the species (a) and (b) make the same or almost the same demands on other species in the community and compete in the same way as each other. In such a model (a) and (b) compete against each other but in a mutually exclusive way-sharing a total number of

individuals (a+b) in proportion to their competitive vigour. (This treatment comes close to a formal definition of the 'niche'.) The question that Naegeli posed was: what changes occur in any given number of individuals, how do they succeed one another and what state of permanence do they achieve when certain assumptions are made about the length of life and conditions of replacement in both forms?

His model develops from z/d+ $z_1/d_1=e+e_1$  where z/d and  $z_1/d_1$  are the annual wastages of the two forms (a) and (b) respectively and e and  $e_1$  the corresponding new colonists: e and  $e_1$  are variable but constant in their relation to one another. Naegeli used iterative procedures to show the simple consequences of varying parameters but historically the most fascinating part of the paper is his choice of special cases that he considered biologically relevant.

In the simplest model he assumed (1) that the life span of both forms and the ratio of their replacements solely on supposedly constant hereditary and ecological factors and that the values of  $d+d_1$  and  $e+e_1$  are independent of one another of  $z+z_1$ . He noted however that (2) the life span of a form may depend on its numbers or the numbers of its competitor (that is, density-dependent control of life span). He modelled the life span of a dependent on the numbers of a; on the numbers of b; and on the numbers of a+b.

He also modelled the three comparable situations (3) in which the annual replacement rate is dependent on the number of individuals. He envisaged positive effects such as the presence of older plants protecting seedlings and negative effects when the presence of many old individuals deprive young

Toehole for a toad

growth of some limiting nutrient. Alternatively (4) the annual replacement of one form may be altered by the numbers of other forms or (5) the annual replacement of either form can be altered by the numbers of both forms acting together. He also considered interactions between the replacement rate and the life span: (6) the annual replacement can be modified by the life span of the individuals of the same form or (7) of the other form.

The essay uses the twentieth century concepts of density dependence and frequency dependence (though not the words). The models are deterministic but he was aware of the significance of chance events and noted the high chance of random extinction of a species when its frequency balances at very low numbers. Many of the interactions he chose to model were nonlinear and he was particularly interested in models in which the square root of density was considered. He concluded that there were very many model situations in which even closely related species would not exclude one another. Today after an era in which most population biologists have struggled to explain diversity, it is curious to see the argument inverted with mutual exclusion regarded as the case needing explanation.

It was a remarkable vision which saw that the outcome of a struggle for existence depended on the comparative effects of intra- and inter-specific competition, that the effects might not be linearly related to density, that (though he did not develop the point further) it was practicable to define the effect of the density of one species by some factor into the effects of the density of another, and that the probability of extinction was relevant when numbers became small.

Naegeli had very great influence on botanical thinking in the nineteenth century. He made important studies of algal structure and life cycles and published classic early work on plant anatomy and ultrastructure. He contributed much to the debate on evolutionary theory and studied the mechanism of inheritance (unfortunately choosing the apomictic Hieracum as his experimental material). All of these activities are reported in the long obituaries by Vines (Proc. R. Soc., 51, 27; 1892) and Scott (Nature, 44, 580; 1819) and in the outline of his life in Gillespie's Dictionary of Scientific Biography (9, Scribner, New York, 1974). None of these even mentions "The Displacement of Plant Forms by their Competitors". The paper must, in 1874, have seemed quite irrelevant to what biology was all about. In 1974 it has little to contribute to advancing ecological science but holds a fascinating place in the history of ideas.

## ... and a bicentenary for science writing

from Peter J. Smith

OLIVER GOLDSMITH, who died just 200 years ago, is one of those unfortunate writers whom most modern critics find it fashionable either to denigrate or ignore, but whose literary stature remains obstinately undiminished among a wider public. Admittedly, his masterpieces were few; Goldsmith's fame rests largely on one poem, The Deserted Village, one novel, The Vicar of Wakefield, and one play, She Stoops to Conquer. He was above all and by necessity a hack writer, though one who peformed with skill.

By far the most important piece of hack work Goldsmith turned out was his An History of the Earth, and Animated Nature (1774), a remarkable eight-volume study. If it seems strange to find a poet, novelist and dramatist writing with some authority on a scientific subject, it needs only to be remembered that in the eighteenth century the disastrous split between science and the humanities had not developed to its present state. Moreover Goldsmith had studied medicine in Edinburgh and Leyden and would thus have had some feeling for the scientific methods of the day. As a writer to order he would in any case presumably have been willing to turn his hand to most subjects. Samuel Johnson is recorded as saying that if Goldsmith could distinguish between a cow and a horse that was about as far as his knowledge of animate nature went, although this flippancy was later to be balanced by the more serious admission that Goldsmith "has the art of compiling, and of saying everything he has to say in a pleasing manner. He is now writing a Natural History and will make it as entertaining as a Persian

So what was the nature of this compilation? The last seven of the eight volumes, which are concerned with the "animated nature" of the title, I leave to the naturalists to judge. Of particular interest to Earth scientists, however, is the first volume which is complete in itself. Goldsmith's purpose in this volume was to give a comprehensive view of the Earth and its physical, inanimate characteristics, which he does in the form of a progression from the globe as a whole ("a sketch of the universe") to more localised features such as mountains, rivers, tides and winds. On the way he deals with the Earth's surface, its internal structure and theories of its formation; he describes fossils, earthquakes and volcanoes; he speculates on the formation of new islands, the origin of rivers and erosion by the sea; he discourses

on air, meteors and the saltiness of the oceans. In short, he gives a general and accurate picture of how the Earth was viewed in the late eighteenth century; and he does so, moreover, within a logical framework which most writers of books about the Earth have adopted ever since.

As Goldsmith freely admits, the model for his first book was Buffon's Histoire Naturelle; but whereas Buffon was out to establish his theory of the Earth above all others and was quite happy to make some of the facts fit his case. Goldsmith had no axe to grind. He was concerned to be more critically objective and discriminating, and thus went beyond Buffon to Burnet, Woodward, Whiston and other sources, both acknowledged and unacknowledged. But from wherever his information came, his judgement was always on the alert and he was ever ready to discard the opinions of others, however eminent, if they were refuted by personal observation.

Goldsmith never lost sight of his intention to write not a scientific treatise but a popular account; his concern was to produce "innocent amusement for those who have nothing else to employ them, or who require a relaxation from labour". The result is a book which is both scientifically accurate (for the time), and a work of genuine literary merit written with what Jeffares (Oliver Goldsmith, British Council, 1959) calls "all the ease and grace we expect from Goldsmith". In seeking "to drag up the obscure and gloomy learning . . . to open inspection" rather than to publicise scientific advances or make a scientific case Goldsmith must be regarded as one of the earliest of what are now called 'science writers'.

During the following century, Goldsmith's An History of the Earth, and Animated Nature went into at least 23 editions, including one in Welsh. His model was copied by scores of writers during the nineteenth century. Could it be that Goldsmith's science writing and its legacy, ignored by scientific and literary historians alike, actually affected the public mind more than many of the better known purely literary works?

## A night on Mount Hamilton

by John Gribbin

THE Lick Observatory on Mount Hamilton, near San Jose, has an interesting history and a fine array of telescopes which make it well worth a visit from any itinerant astronomer (or ex-astronomer) who happens to be in the neighbourhood. I was in that happy position on October 25, and my native

guide, Dr John Faulkner, was also able to provide a potted history of the observatory. (For further details see the booklet *Lick Observatory*, fifteenth edition, available from the University of California, Santa Cruz.)

It seems that James Lick, who provided the finance for the building of the observatory, now rests in a tomb underneath the 36-inch refractor. He originally intended that the memorial by which the good citizens of San Francisco should remember him would be a pyramid downtown, rather larger than that of Cheops. He was dissuaded from this by a retired sea captain who pointed out the great lustre that could be brought to the name of Lick by an observatory containing the largest telescope in the world. After a costly site survey covering much of the United States (and the first of its kind) Lick and his seafaring friend were no doubt delighted to find that Mount Hamilton, in their own backyard, was as good a site as any available.

Building an observatory on the top of a mountain was an epic achievement in the 1870s. The builders did, in fact, cheat a little on Lick's bequest, since they did not feel up to the task of building a reflector bigger than the Earl of Rosse's remarkable Irish instrument. Instead they built the largest refractor in the world.

Since those days, the Lick Observatory has expanded, and so, alas, has the nearby town of San Jose. The pretty lights below the mountain and the haze from the urban environment conspire to plague the astronomers. But although there is talk of a new observatory being built in a less accessible part of California, there are no definite plans as yet.

Pride of place on the mountain today is taken by the 120-inch telescope, which the Lick observers claim to be the best light bucket in the world. The impressive array of electronic gadgets which can be attached to it makes the telescope, they claim, a better performer even than the 200-inch at Palomar, although the Lick instrument has just 36% of the collecting area of the larger telescope. But they may soon have to consider a new rival to the telescope which can get the most in-

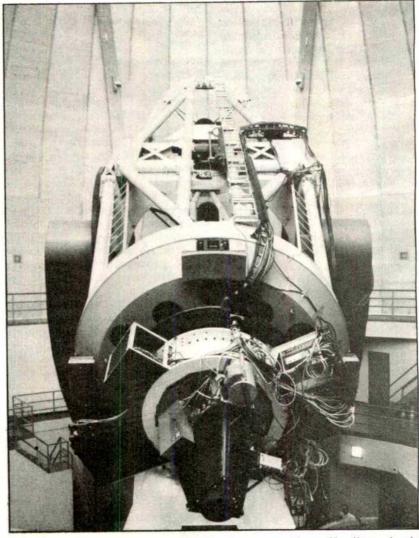

Fig. 1 The business end of the 120-inch telescope on Mount Hamilton, showing the impressive array of electronic instrumentation. (Courtesy Lick Observatory.)

Fig. 2 "It was a dark and stormy night . . ." View of the main building of the Lick Observatory from close to the 120-inch site. The small hut in the middle ground conceals the absence of any electronic instrumentation on the Tauchmann.

formation out of the smallest number of photons—the Anglo-Australian Telescope, whose director, Jo Wampler, must have taken with him from California many of the tricks of the trade.

But the casual passer-by is not allowed even to enter the 120-inch dome, much less operate the mighty machine. For such itinerants, a slightly less sophisticated instrument with an aperture one sixth that of the big telescope is available. This instrument, the Tauchmann reflector, provided the entertainment on the night of my visit. In the words of one recent user it provides "a rickety but fun operation". The meaning of this can best be gauged from the instruction book provided to aid the unfamiliar with their observations. After explaining how to open the dome (not as easy as the uninitiated might guess) and how to set the telescope in the required direction, some handy hints are provided to explain why you may not be able to see anything. The list begins: "(1) Is telescope pointing out of dome slit?" and continues in similar vein.

Our fun was only slightly marred by the 99% cloud cover on the night of October 25. We did, briefly, see the Moon and my colleague claims that he saw Jupiter, but the observation was not confirmed. As the only observers on the mountain that night we can at least report that for once the Tauchmann achieved more than the 120-inch. Of course after a two hour drive back to Santa Cruz on the coast we found a cloudless sky, thus proving Parkinson's second theorem.

#### **Chunky sputtering**

from Robert W. Cahn

THOSE incorrigible optimists who look for salvation to the large-scale controlled release of thermonuclear fusion energy should be cheered by a conference which was held at Argonne National Laboratory near Chicago last January, under the title Surface Effects in Controlled Thermonuclear Fusion Devices and Reactors. The proceedings have now been published as a special volume of the Journal of Nuclear Materials. For perhaps the first time, a major conference took as a premise that large fusion reactors will be built well before the century is out; Klaus Zwilsky of the Division of Controlled Thermonuclear Research of the United States Atomic Energy Commission proffered a timetable which included an experimental power reactor in operation by 1984. The conference was concerned with one class of engineering problems which will arise in the design of such reactors, namely the interaction between imperfectly confined plasmas and the wall of the containing vessel, combined with more conventional radiation damage due to energetic particles, especially neutrons, impinging on the walls. Physicists and metallurgists do not lavish time and money on such difficult studies unless hard-headed engineers have concluded that the hardware is in principle feasible.

Many of the papers dealt with the effects of particles peculiar to thermonuclear reactors, such as lithium, deuterium and tritium ions, but a particularly intriguing group of papers was concerned with that familiar entity, the high-energy neutron. The neutrons impinging on a fusion reactor wall will be exceptionally energetic, and little is known concerning the effects of such super-neutrons. Kaminsky and Das (J. nucl. Mater., 53, 162; 1974) experimented with 14 MeV neutrons from an accelerator, impinging on niobium. It has long been realised that the sputtering (that is, collision-induced erosion) of the metal could gradually damage the wall, and perhaps more serious, contaminate the plasma with metal ions through the knocking-out of individual metal atoms. But something else quite unexpected happened as well. 'Chunks' of niobium often exceeding one micrometre in size and containing many millions of atoms, were emitted from the surface. Nothing remotely like this had been reported before in sputtering experiments. Kaminsky and Das discovered that the emission of chunks was much greater when the target was cold-rolled and roughly polished than when it was annealed and finely polished; though

these aspects were not varied independently, the investigators were sure that internal stresses and rough surfaces each and severally promote emission of chunks (as opposed to single atoms).

A companion paper by Guinan (ibid, page 171) develops the hypothesis that thermal transients engendered by collision cascades within the metal will generate shock waves which might suffice to spall off chunks. Guinan concludes that the magnitude and duration of such shock waves would not alone suffice to do the trick. But if the metal contains regions of high internal stress (for instance, at the head of a dislocation pile-up) then as Guinan shows, a shock wave can act as a trigger to release the stored internal energy, leading to the ejection of a chunk. On this hypothesis, as Karminsky and Das have found, both plastic deformation and surface roughness will foster chunk emission (though it must be admitted that the role of the second variable is not clearly explained). Unannealed cold-rolled foils, which contain macro as well as micro stresses, are particularly vulnerable. Karminsky and Das conclude that a high mirror polish on a vacuumannealed metal, monocrystallic for choice, will render it virtually immune to chunk emission or the associated damage. It seems the phenomena resembles ordinary fatigue, very largely controlled by surface quality.

In related studies, Blewitt et al. (ibid., page 189) failed to find chunks emitted from gold bombarded with 14 MeV neutrons, whereas Biersack, Fink and Mertens (ibid., page 194) found copious chunk emission when UO2 films were sputtered by selfgenerated fission fragments during neutron irradiation. Here there was a pronounced effect of foil thickness (thin foils emit more chunks), and in particular, there was a lower limit of neutron dose below which no chunks emerged. It is surprising that the many earlier experiments on fissionfragment self-sputtering had not previously uncovered this phenomenon.

The notion, which seems well supported by the experiments on niobium, of the cold-rolled metal as a sort of self-stressed microbomb from which fragments are released by neutron bombardment, is reminiscent of researches at Harwell in 1956 by Cottrell and Roberts, who discovered that the intergranular stresses engendered by uranium by the anisotrop radiation-induced growth of individual crystal grains led to creep / absurdly small applied stresses the external stress triggers/ release of internal stresses prolonged uranium fissio. creep has come to be rec

major hazard in fission reactions, and it may be that chunk emission must be guarded against with equal care in the fusion reactors of the future.

#### Cancer in Tuscany

from R. A. Knight and N. A. Mitchison Banners decked the streets of Florence, Sienna, Montecatini, Pisa and Lucca, for the 6,000 members who came to listen to papers given at the Eleventh International Cancer Congress by some 4,500 authors on October 20-26. Buses and trains shuffled to and fro between the five cities, but we found the delight of autumn in Tuscany compensated for the fuss. The congress accurately conveyed the flavour of cancer research over the past four years: greatly to oversimplify it was one of slow progress in cell biology and immunology, with dramatic news concerning viruses. We listened to the virology and immunology papers.

In the RNA tumour virus field, new work localised specific viral antigens on the tumour cell surface. D. P. Bolognesi (Duke University) showed that monospecific anti-p30 and antigp71 sera were cytotoxic for virus producer and non-producer methylcholarthene induced mouse tumours, although the anti-p30 effect may be mediated by antigen non-specifically absorbed to the cell surface. Natural mouse antibody is also cytotoxic for these cells, and can be partially absorbed both by gp71 and by p30. The predominant anti-viral antibodies in the serum of normal wild and laboratory strain mice, reported by R. C. Nowinski (University of Wisconsin), react with p15, and with both viral envelope glycoproteins. Nowinski also finally laid to rest the old dogma that mice cannot mount a humoral anti-p30 response, since this is the major specificity in the serum of C57BL mice immunised with the K36 leukaemia.

Several workers discussed the relationship of oncogenic viruses to human tumours. G. Klein (Karolinska Institute) reported that although 98% of African Burkitt lymphoma biopsies were positive both by nucleic acid hybridisation for EBV DNA, and for the Epstein-Barr nuclear antigen, European cases were negative for the genome. S. Speigelman (Columbia University) summarised evidence from his laboratory for an association between 70S RNA and a reverse transcriptase-containing. particle in a variety of human tumours, and showed that this agent contained a protein which cross reacts with p25 from the Mason-Pfizer agent. R. C. Gallo (National Institutes of Health) found that antisera to primate virus reverse transcriptase cross react with m antigen from human leukaemic cells,

and that human tumour cells contain an antigen cross-reactive with primate virus p30. Visual sightings of the mature Ctype particles in human tissue material, however, are rare. Non-enveloped particles, which contain 70S RNA and viral antigens (virosomes), and which actively incorporate labelled precursors in vitro, were described in the mitochondrial membrane of avian and murine tumours by J. Kara (Czechoslovak Academy of Sciences, Prague). These particles are more prominent in nonproducer tumours. Although the Spiegelman particles, but not the oncornavirus precursors identified in human cell lines by A. Bukrinskaya (Academy of Medical Sciences, Moscow), differ from virosomes in density, more than one worker went home anxious to isolate human mitochondria. Thus immunology's most useful contribution to cancer research at present may be in the identification of candidate human tumour viruses.

Many papers dealt with the immune response to tumour-specific antigens. On the clinical side, the meaning of cell mediated immunity in vitro was questioned in several papers, for example by M. Takasugi (University of California, Los Angeles), R. W. Baldwin (University of Nottingham), and F. J. Cummings (Brown University): the popular microcytotoxicity test can no longer be accepted as a measure of the response of the patient to his own tumour. Significant responses, if they occur at all, seem to do so most clearly with a restricted range of tumours which include bladder carcinoma, melanoma and sarcomas. Encouraging results were reported with 'immunotherapy'—both specific (with administration of tumour cells or membrane preparations) and nonspecific (with immunological adjuvants such as tubercle bacilli, where C. Maruyama (University of Tokyo) had particularly extensive data). In no case, however, was there decisive evidence of the involvement of an immune mechanism.

The use of immunological methods to detect and monitor tumour growth was concentrated mainly on carcinoembryonic antigen for carcinoma of the gut and alpha-foetoprotein (AFP) for hepatoma, with limited use of cellular immunity against cell lines in other types of cancer. Papers from Europe and the United States, all of which took a cautious line towards widespread population screening were \*dwarfed by one from the Coordinating Group for AFP (Pekin) which included data from a massive screen of 500,000 individuals. Those who wish to evaluate the test wait, therefore, to see whether the Chinese find the effort worthwhile.

Analysis of the immunological mechanisms which operate in animal tumour systems continues. The entire response

from induction to final killing can now be obtained in vitro, and the killer cells thus generated are highly active (J. C. Cerottini, Institute of Cancer Research, Lausanne). Efforts to characterise the antigens involved have now reached the stage reached 5-10 years ago with the major transplantation antigens. Virus-coded cell surface antigens are better characterised, and are available in some instances for in vitro manipulation with lymphocytes (G. R. Shellam, Imperial Cancer Research Fund, London). From the strictly immunological standpoint the furthest advance was reported by K. Rajewski (University of Koln), who has rendered antigens obsolete by elicitating a response with anti-idiotypic antibody, that is, with antibody directed against the antigen-combining region on the receptors of a clone of lymphoytes. Since his procedure stimulates T lymphocytes as well as B lymphocytes, it implies-subject to certain safeguards in interpretationthat T and B cells read from a common dictionary and share a common pool of receptors.

## Tumour viruses at Munich

from a Correspondent

TUMOUR virus meetings tend to have the same speakers, discuss the same subjects and send their participants away asking the same question: what do tumour viruses have to do with tumours? The clinical oncologist must helplessly face this question every day; meanwhile the basic oncologist faces the statistics that 60-90% of all known malignancies in man are caused by chemical carcinogens and that in no case so far have the candidate human cancer viruses been firmly identified as a cause of cancer in man. Their problems are intensified by the gap between experimental tumour research and clinical oncology. The tumour virus meeting held at the Max-Planck Institute for Biochemistry, Munich, from October 4 to 10 provided a good opportunity for communication between basic and clinical oncologists.

Dr R. Gallo (National Cancer Institute, Bethesda) discussed his concept of class I and class II viruses. He showed that the RNA genome of class I viruses (typical endogenous viruses such RD-114) hybridises virtually completely to DNA of normal uninfected cells. These virogenes may be incompletly expressed and their products, such as reverse transcriptase, can be associated with normal tissues. Class II viruses show much less hybridisation of their RNA genome to uninfected cell DNA. Members of this class, for example murine and feline leukaemia

and sarcoma viruses, can probably be transmitted horizontally.

Dr S. Spiegelman (Columbia University) who has little faith in inherited oncogenes, presented evidence which certainly speaks in favour of horizontal transmission. In his studies with identical twins he has found that the leukaemic twin contained particle-related DNA sequences that could not be detected in the leukocytes of his identical healthy sibling. Dr S. Dube (Max-Planck Institute, Göttingen) suggested that the mechanism of neoplasia could involve somatic hypermutation of vertically transmitted endogenous type C virogenes; if this hypothesis is correct, Dr Spiegelman would have seen no difference between leukaemic and healthy siblings if he had looked at germ line rather than leukocyte DNA.

Work on viral structural proteins is progressing rapidly. Drs Moenning and (Max-Planck Hunsmann Institute. Tübingen) described the purification and characterisation of the major coat protein p30 (molecular weight 30,000) and the major envelope glycoprotein gp71 of Friend erythroleukaemia virus. They showed that gp71 must reside in the surface knobs because treatment with bromelin removes both knobs and gp71. Dr M. Strand (Albert Einstein College, New York) reported that she finds an additional glycoprotein, gp69. Each of these proteins contains distinct interspecies antigenic determinants. The gp69/71 mixture can induce neutralising antibodies and thus seems to be potentially the most useful antigen for the preparation of vaccines. Dr F. Lilly (Albert Einstein College, New York) showed that gp69/71 is non-coordinately expressed with the p30 protein but appears to be partially linked to sarcoma genes. Dr Vaheri (University of Helsinki) using radioimmunoassay, showed that leukosis-free chicken cells expressed low concentration's of p30, but after infection the cellular concentration of p30 went up by 100-1,000 fold.

The nature of the viral genome was actively discussed. It is generally agreed that the genomic RNA is a 70S aggregate (molecular weight 10<sup>7</sup>) of several 30-35S (molecular weight  $\sim 3 \times 10^6$ ) subunits. Whether the subunits are identical or not has been a major issue. From the extensive genetic and biochemical evidence accumulated by Dr Vogt (University of Southern California, Los Angeles) and Dr Duesberg (University of California, Berkeley) it seems that the genome of Raus sarcoma virus is polyploid; that is, the subunits are identical. This supported by the independent findings of Drs Baluda (UCLA), Billeter (University of Zurich) and Dube.

Drs Wu and Gallo have been

studying compounds which affect virus replication and virus-induced transformation and which may therefore have clinical value. Dr Wu described the inhibitory effects of rifamycin SV derivatives on proviral formation and cordycepin on virus production at an early post-transcriptional step. Dr Chandra (Frankfurt) reported on the inhibitory effect of thio-polynucleotide homopolymers of cytidylic acid and uridylic acid.

#### Energy in agriculture

from N. R. McFarlane

At a meeting on October 21 held at the Society of Chemical Industry, chemical and mechanical aspects of energy utilisation in agriculture were discussed.

J. J. Landsberg of Long Ashton Research Station pointed out that the conversion of solar energy into useful biomass is an inefficient process. Man's efforts to increase useful biomass in agriculture moreover require considerable energy input in the form of fertilisers (Professor G. W. Cooke of Rothamsted Experimental Station). While other agricultural chemicals such as herbicides are less energetically demanding, requiring similar energy inputs to mechanical weeding methods (Dr M. B. Green of Imperial Chemical Industries) they are also less effective than fertilisers. The link between solar sources of energy and chemical energy was provided in the discussion of the direct use of coal, oil and gas for heating and mechanical operations on the farm and in the glasshouse (G. F. Sheard, Glasshouse Crops Research Institute).

The paper which created most discussion was that of Dr K. L. Blaxter of the Rowett Research Institute, who showed that known world reserves of energy (42×10<sup>15</sup> MJ) are equivalent to but two years of European sunshine! His Table 1 shows that only 11% of the total plant material harvested in the United Kingdom is 'farm gate' output, destined for human consumption. After processing this primary plant food

Table 1 Biological energetics of agriculture in the United Kingdom

yields 65 MJ×10° yr<sup>-1</sup> of energy for human consumption. 70% of the prime plant output is eaten by farm livestock—a reflection of the importance of the animal sector in British agriculture. Table 2 was also presented by Dr Blaxter to show the high energy inputs besides solar energy needed to maintain the agricultural output.

Both Professor E. W. Russell (University of Reading) and Dr R. J. Martin of Plant Protection Limited criticised short term economical evaluation of depleting natural resources. The message I received was that true economic value will not be placed upon such items as fossil fuels until it is too late. Even the use of conventional economic evaluation under such circumstances is somewhat suspect.

## Immunity and connective tissue

from A. C. Allison

THE Fifth Lepetit Colloquium on The Immunological Basis of Connective Tissue Disorders was held in Madrid on November 11-13. M. Mannik (University of Washington) described the self-association of IgG rheumatoid factors to form stable dimers in which one antibody binding site on each molecule reacts with an antigenic determinant on the Fc region of the other molecule. The calculated association constant for this dimerisation is remarkably high (10<sup>10</sup> l mol<sup>-1</sup>). In addition a concentration-dependent aggregation of dimers into tetramers. octamers and higher polymers is observed. The self association of rheumatoid factors may play a part in perpetuating immunologically mediated synovitis. Complexes of IgG and IgM antiglobulins that precipitate in the cold (cryoglobulins) are sometimes associated with renal disease (E. Franklin, New York University) and some patients with systemic lupus erythematosus (SLE) have been found to have idiotypic markers of monoclonal cryoglobulins in their renal lesions (H, Kunkel, Rockefeller University).

Several laboratories have been studying the antibodies against human T and B lymphocytes, some reactive only in the cold and others at 37° C, present in patients with SLE, rheumatoid arthritis (RA) and infectious mononucleosis. Messner (Albuquerque) reported the presence of cytotoxic antibodies against lymphocytes in the majority of family members of patients with SLE, irrespective of consanguinity. A virus or other transmissible agent may be involved.

F. Dixon (Scripps Clinic, La Jolla) emphasised the analogy between the role of endogenous virus antigens in mice and the appearance of SLE in humans. In all mouse strains virus-specific antigens are found, and in some strains complexes of these antigens and antibodies, as well as nucleic acids and antibodies, accumulate in the renal glomeruli.

R. Lerner (Scripps Clinic, La Jolla) presented evidence obtained in his

laboratory and that of E. Boyse in New York that a mouse thymocyte differentiation marker, GIX, is the same as a glycoprotein (gp70) in the virions of murine oncornaviruses. The oncornavirus genomes are integrated in the host genomes, and the expression of gp70 is under control of factors both genetic (manifestation on the membrane of thymocytes in GIX+ strains only) and environmental (manifestation only under the influence of the thymus). In G<sub>IX</sub> strains the antigen is present only in leukaemic cells. Thus the distinction between virus and host gene products becomes tenuous, and whether immune responses to them are regarded as autoimmune is a question of semantics. As in mice and chickens, all human cells seem to have in their genomes lengths of DNA hybridising with oncornavirus nucleic acid, and the number of copies of oncornavirus DNA is increased in SLE and leukaemia.

B. Pernis (Basel Institute for Immunology) pointed out that most human B lymphocytes have surface IgM as well as IgD, the proportion varying from cell to cell. These turn over at different rates: when they are lost after capping or protease treatment IgM is resynthesised much more rapidly than IgD. W. Hijmans (Institute for Experimental Gerontology, Rijswijk) reported that the only surface immunoglobulin of lymphocytes in young human foetuses is IgM, which invalidates the view that IgD is the first to appear.

H. Muller-Eberhard (Scripps Clinic, La Jolla) described the amino-acid sequence of the complement component C3. The cleavage product C3a requires a high  $\alpha$ -helical structure for activity. When C-terminal arginine is removed from C3a, the product binds to mast cell receptors and norepinephrine receptors of blood vessels and blocks their activation. K. Austen (Harvard) emphasised the symmetry of the steps involved in activation of complement by the classical and alternate pathways. Both pathways are activated in the joint fluids of rheumatoid arthritic patients. Austen concludes that the alternative pathway is activated ab initio but another explanation, that there is feedback activation from the classical pathway, is difficult to exclude.

J. Natvig (Institute of Immunology and Rheumatology, Oslo) reviewed recent observations on the heterogeneity of amyloid. A non-immunoglobulin AA protein from tissues of different patients shows identity over most of the 76 residues but some variation in the C-terminal region. Levels of the related serum component (SAA) are increased in sera of patients with rheumatoid arthritis and in old people. An immunoglobulin isolated from amyloid shows homology with  $\lambda$ -chains over the first 45 residues and seems to represent a new  $\lambda$ -variable subgroup.

L. Glynn (Kennedy Institute, London) discussed his model of persistent monoarticular arthritis following intra-articular injection of antigen into previously immunised animals. Complexes of antigen and antibody are found in menisci, but it is not clear whether these have any pathogenetic role. Release of hydrolytic enzymes from mononuclear phagocytes exposed to immune complexes or products of activated lymphocytes, discussed by A. Allison (Clinical Research Centre, Harrow), may be involved in joint damage in rheumatoid arthritis. There is still no convincing evidence of any causal role of an infectious agent in rheumatoid arthritis.

#### Immunopathology of parasitic infection

F.E.G.C. REPLIES to the responses in Matters Arising last week (252, 509; 1974) to his News and Views article (246, 187; 1973).

My statement that "most parasites are capable of evoking immune responses in their hosts but these are seldom effective in eliminating the infection" implies that some parasites do mount effective immune responses. Professor Urquhart and Dr Miller both refer to lungworm disease of cattle thus stressing the comparative rarity of the latter situation. It is true that there are well defined immune responses that eventually result in some degree of protective immunity against parasitic infections. But it is equally true that the actual elimination of the parasites as a result of an immunological response is not commonplace. The major parasitic diseases of man (malaria, sleeping sickness, Chagas' disease, American leishmaniasis, schistosomiasis and filariasis) are characterised by infections that last months or years. To most people this indicates a failure of the immune response to eliminate the infection. The immune response may ameliorate the disease symptoms but transmission of the parasite still occurs. Domesticated animals are more fortunate than man in being able to mount effective immune responses but in piroplasmosis and fascioliasis these responses are not very effective. It must also be remembered that helminth infections may diminish as a result of the natural death of the worms and not an immune response. This aspect of recovery from infection has been

little studied.

My statement that "the possibilities of developing useful methods of immunisation [against parasitic diseases] fade further and further into the distance" does not imply that immunisation is always going to be impossible. Vaccination against cattle lungworm, canine hookworm and certain kinds of piroplasmosis has been achieved but the vaccines used, irradiated larvae or infected blood, are unacceptable in the field of human medicine. With the development of a vaccine against cattle lungworm nearly twenty years ago, it was felt by many workers that the solution to the problem of vaccination against parasitic infections was just round the corner. This early optimism has not been justified. As more and more is discovered about immunity to parasitic infections further complications are uncovered. The development of vaccines against many parasitic diseases may not be possible before the diseases are eliminated by drugs or public health measures. Trichinellosis is a case in point. There have been encouraging reports of possible immunisation procedures against Trichinella but its decline in the United States has been brought about by legislation designed to prevent swine fever. Studies on the immunological responses to parasites have been amply rewarded by discoveries in pure immunology, the development of immunodiagnostic techniques and an understanding of many immunopathological conditions. Vaccines will also be developed as a result of these studies—but not for many years to come.

Christmas quiz

- 1. Who says we should harness eccentric buoys?
- 2. What is the next number in the series 1, 2, 3, 5, 8, 13, 21, 34, 55 ... and in what way is this series linked both to Pisa and to leaves?
- 3. What professor of chemistry wrote an opera whose most famous tune was, many years later, used in the musical 'Kismet'?
- 4. She wanted his next book dedicated to her and indeed it was—but instead of being a story of wide popular acclaim, it was an elementary treatise on determinants. Who was she?
- 5. Who has an answer to Logical Positivism in the 'family Four Position Base'?
- 6. Appearing twice a year, they are common in India, China and Japan but are probably indigenous to western Asia. In ancient Egypt one variety was accorded some degree of divinity and is featured on monuments of that period. If you had one what would you do with it?
- 7. He studied in Vienna and by the age of 26 had become Professor of Mathematics at Gratz University. Four years later he moved to the Chair of Physics in Vienna, and it is as a physicist and psychologist that he is remembered most. Towards the end of his life he became a member of the Austrian house of Peers. The rather one sided view from one of his philosophical works was featured briefly in a recent edition of *Nature*; what was it and who was he?
- 8. What was the concept that was first suggested publicly in an address in Frankfurt am Main in January 1912; and who delivered the address?
  - 9. Where and when did the largest single oil spill occur?
- 10. What is the most commonly used tricyclic anti-depressant and what are the main effects of such compounds?
- 11. What is dendrochronology and what importance does it have in art?
  - 12. Of what biochemicals are these the empirical

- formulae: (a)  $C_{35}H_{28}MgN_4O_5$ ; (b)  $C_{63}H_{88}CoN_{14}O_{14}P$ ; (c)  $C_{34}H_{32}ClFeN_4O_4$ ?
- 13. Name the group which in 1974 officially wanted restriction restricted?
- 14. By what discovery in 1974 was St Bartholomew's Hospital specifically linked to a gene deletion?
- 15. Which enzymes are deficient in: (a) Fabrys disease; (b) Sandhoffs disease; (c) Pompes disease?
  - 16. Who saw fruit in a padded cell?
- 17. From where, precisely, was Marconi's first transatlantic radio transmission made?
- 18. How many optical telescopes bigger than 100 inches are in operation or under construction in the Southern Hemisphere and where are they?
- 19. Some useful quotations for authors to know—but who said them first?
- (a) Accuse not Nature, she hath done her part ...
- (b) can't be Nature . . . not sense . . .
- (c) except the blind forces of Nature, nothing moves in this world ...
- (d) The fault was Nature's fault not thine ...
- (e) What's a' the jargon of your schools; Your Latin names for horns and stools; If honest Nature made you fools.
- (f) Thrice happy he who not mistook Hath read in Nature's mystic book ...
- (g) to be constant, in Nature were inconstancy . . .
- (h) Nature is always wise in every part . . :
- (i) Nature abhors imperfect work . . .
- (i) But in them Nature's copy not eterne . . .
- (k) Nature knows a thing or two . . .
  - 20. Who wrote:

Nature and Nature's laws lay hid in night: God said let Newton be! and all was light and who replied with what?

21. For what work did the following win Nobel Prizes: D. Bovet (1957); J. Heyrovsky (1959); G. von Bekesy (1961); G. Wilkinson (1973)?

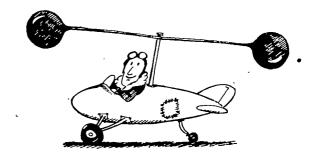

See page 622 for answers.

### Spinning into space?

RECENT publicity about possible 'antigravity' devices which seem to defy Newton with the aid of a spinning top or two encourages us to offer for seasonable speculation the following question, taken from the 1969 Christmas Examination for Junior and Senior Honours in the Natural Philosophy Department of the University of Aberdeen. There is no prize for any correct answer, and no answer is presented in the pages of this issue of *Nature*.

"There is currently an application for a patent for an antigravity device based on the following argument:

'A particle at the Earth's surface has a critical horizontal velocity  $\nu$  such that this velocity will cause it to orbit the Earth in a circle. If this velocity is exceeded, the particle will tend into an orbit at a greater mean distance from the Earth's centre. The actual direction of the velocity in a horizontal plane makes no difference to the foregoing conclusion. Now such a horizontal velocity can in principle be achieved by spinning two particles joined by a horizontal bar as in a dumbell. Each particle can thus be

made to have a velocity V which is greater than v, and so they should jointly rise. The proposed method of defying gravity therefore consists in spinning a dumbell fast enough.

What is the flaw in the argument, and how would you try to persuade the inventor (an imaginative engineer who might not be convinced by an argument based on the motion of a common centre of gravity) that he would be foolish to waste money on pursuing the patent?"

### Science journalists come of age in Pisces

John Gribbin\*

It seems that more science journalists are born under Pisces than any other sign.

WINDSOR<sup>1</sup> has pointed out that the astrological belief in the importance of the 'Sun sign' as an influence on personality seems to be reflected in the distribution of birth dates of American biologists. In particular, he found that molecular biologists tend to be born under Aries. I have now compared the birthdays of science journalists found in the London office of *Nature* with those of all staff members found in that office. The birthdays were obtained by personal questioning during August, 1974, and the appropriate Sun signs were assigned.

More science journalists were born under the sign of Pisces than any other sign (Fig. 1), and relatively few (zero) members of the *Nature* staff were born under Aries, Taurus or Gemini. In spite of the small size of the sample, the result is significant as indicated by Lynden-Bell's half-power test. This test uses the criterion that in statistics, all numbers go as the square root (D. Lynden-Bell, unpublished).

Taking the data for science journalists alone, there are eight Pisces and eight others (including one "no comment"). The most densely populated Sun sign other than Pisces is Leo, with just two members—less than even the half-power of the Pisces population.;

It may also be significant that of the Leo population one (E) is the Editor of *Nature* and the other (DE) is Deputy Editor.

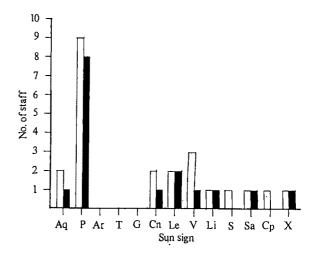

Fig. 1 Frequencies of Sun signs of *Nature* staff. Open histogram, all staff; solid histogram, science journalists only; X, birthday not revealed ("no comment").

While these results are suggestive, further observations of a larger sample are needed before any firm conclusions can be drawn.

# Ambisonic reproduction of directionality in surround-sound systems

P. B. Fellgett\*

In both the technology and the aesthetics of extending high fidelity reproduction to surround-sound, reproduction of natural ambience is crucial. The 'quadraphonic' attempt to reproduce four stereoblended tracks, derived from multi-microphone mix-down, cannot provide this. Complete spherical directionality can however be encoded on to a minimum of two audio channels to produce acoustically acceptable surround-sound systems. Limitations are set both by the number of available loudspeakers and by the number of channels.

The history of representational art has many examples of what people of a particular age and culture were unable to perceive, and therefore to reproduce; for instance the inability of the dynastic Egyptians to perceive that the full-face eye is not seen in a profile figure. The reproduction of sound follows a similar pattern. In the early development of the phonograph and of 'wireless' the listener was so satisfied with the novelty of hearing the human voice or music issue from a machine that he demanded nothing else. Indeed there was often little conscious

appreciation that anything was lacking in fidelity of reproduction; how else could Sir Arthur Conan Doyle suppose in *The Adventure of the Mazarin Stone* that Sherlock Holmes could deceive a sophisticated villain into mistaking a 'modern gramophone' of 1927 for real violin playing, even in the next room. As late as the 1930s, many listeners could see little short of perfection in the commercial 'radiogram'.

As the sense of wonder wore off, however, a more critical attitude filtered down from audio engineers to the buying public, and the search begån for high fidelity reproduction.

During and immediately after the Second World War, domestic reproduction of sound depended on the 78-r.p.m.

<sup>&</sup>lt;sup>1</sup> Windsor, D. A., Nature, 248, 788 (1974).

<sup>\*</sup> Address: Department of Engineering and Cybernetics, University of Reading, Whiteknights, Reading RGL 2AL.

shellac disk and a.m. broadcasting. Now with the vinyl disk and f.m. broadcasting, high fidelity reproduction has reached the stage at which the best equipment can make a chamber group sound (to me) like the real thing; but this degree of realism in the reproduction of an orchestra still eludes us. Careful introspection suggests that even this judgement is too lenient, and that we are 'listening-through' major defects which have always been inseparable from reproduced sound, and which therefore we take for granted.

One aspect that is obviously lacking is directionality. Monophonic reproduction gave no explicit directional information, even when reproduced from more than one loudspeaker. In stereophonic reproduction, sound reaches the listener only from the forward direction, whereas in the concert hall the listener is bathed in reverberant sound coming from all directions. In addition, stereo works by feeding common signal-components to a pair of loudspeakers with relative amplitude determined by the position which the illusory sound source is to occupy. It is easy to show that the perception of stereo-imagery is both physically artificial and aesthetically untrue to life; it has to be learnt and some 10% of the population are unable to do this. Moreover, although skilful recording can give some illusion of depth, the acoustic images are essentially strung out along a line joining the two loudspeakers, giving an effect that has been described as a cardboard cut-out orchestra.

### Role of directionality

From the antiphonal tradition through to the school of St Mark's and the baroque, directionality played a large and explicit part in western music. In classical and romantic orchestral music this explicit component is largely abandoned, some composers even preferring a completely blended sound, but nevertheless directionality is important implicitly. A composer necessarily writes with subconscious experience of the relationship between the sections of an orchestra, or between the different departments of an organ and the relationship of these to the choir; it has been said that the works of the Bach family cannot be fully appreciated except on an organ constructed on the Werkprinzip.

Some conductors pay considerable attention to the disposition of the sections of the orchestra, and these relationships should be heard in reproduction. There is little need, however, to pinpoint individual instruments, which indeed is seldom possible in the concert hall. What is important is that each voice in the musical texture should be labelled with an acoustic ambience characteristic of its place of origin. The ability to follow different voices in the musical texture, despite substantial differences in level, is very much bound up with this labelling, as indeed is the appreciation of musical timbre itself.

All these aspects relate to the acoustical reverberance and ambience of the concert hall. If it is worth spending thousands of pounds on the acoustics of a concert hall, then this should be heard in reproduction.

It follows that the highest fidelity in sound reproduction requires that the directionality of sound should mimic both the direct and reverberant sound of the concert hall. This is not just a matter of a vague splash of delayed echoes, but of a relationship between directionality and time-delay which gives specific information; this information is what we shall mean strictly by ambience. Systems capable of reproducing it will be called 'ambisonic'.

### 'Quadraphonic' attempt

In the recording industry it is customary to mix-down multimicrophone recordings onto four-track master tape in which signals are often stereo-blended between pairs of channels. The present upsurge of interest in surround-sound was in some measure triggered by engineers and producers playing back such four-track material directly into four amplifiers and loudspeakers distributed approximately in a square near to the corners of the monitor room.

Mixed-down tapes are unfortunately highly contrived and may have only the sketchiest relationship to natural sound. Moreover the assumption was that directionality should be encoded by pair-wise blending between channels associated with adjacent corner positions. This is a sub-optimal method of encoding, making less than full use of the information capacity of the available channels. Further, in order to achieve this coding using directional microphones it would be necessary for the polar response to have the highly improbable form of a half-cycle cosine wave over one sector of 180°, and zero response over the remaining 180°.

There are also severe restrictions in playback. If four loudspeakers are disposed about a listener, at least one pair must subtend an angle of 90° or greater at that listener. It is well established, however, that stereo blending does not work well when the angular subtense of the line joining the speakers exceeds about 60°. Moreover, stereo imagery works best over the 90° sector in front of the listener, worse at the rear, and worse still at the two sides. The attempt to extend the principle of stereo blending from the front wall to the other three sides of the listening room therefore not only retains all the limitations of stereo itself (outlined earlier) but is necessarily rather poor even judged as stereo.

The above approach is what is usually meant by the term 'quadraphony', although usage is by no means uniform. The name itself is a canard in at least two ways. First, it is a Greek—Latin hybrid, and ought to be called quadrisonic. The second is the identification, by implication, of surround-sound with the need to have four channels. In fact, as we shall see, surround-sound can be realised with as few as two channels. The false assumption that surround-sound is synonymous with four-channel then introduces the need to find distinctive names for two- and four-channel surround-sound systems, which were therefore called 'matrixed four-channel' and 'discrete four-channel', respectively. To prevent confusion I shall not use these jargon terms, and words such as four-channel and matrix will be used simply in their ordinary English and technical senses.

#### More systematic approach

Any system that is to reproduce specific ambience information must embody the following (Fig. 1):

- (a) transduction of the original sound field, including its directionality and acoustic ambience;
- (b) encoding the resultant composite signal, including information about directionality, on to the available communication channels;
- (c) transmitting the resultant information to the listener, including recording and storage of this information where appropriate;
- (d) decoding the channel-signals into a form suitable for feeding to a plurality of loudspeakers;

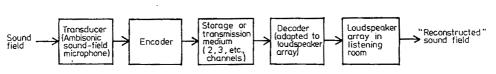

Fig. 1 Basic features of ambisonic reproduction.

(e) radiation from the loudspeakers of sounds which interact in the listening space so as to reproduce, as far as possible, a simulacrum of the original sound field.

Our present systematic understanding of the requirements and possibilities of these steps owes much to the work of Gerzon<sup>2</sup>, particularly his analysis of the theory of encoding and of psycho-acoustic criteria in the reproduction of directionality, much of which is not yet published. The sections which next follow will discuss some of the salient problems in greater detail.

### Sound-field microphones

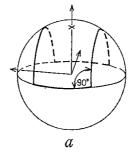

It is first necessary to characterise the sound-field at a given place in the room where the performance is taking place. The sound field at a point can conveniently be characterised in terms of spherical harmonics representing the sound field pressure and its derivatives. The number of spherical harmonics up to and including various orders n is shown in Table 1. From this it is seen that the number of independent signals, each representing a spherical harmonic, is of the form  $(n + 1)^2$ . The 0th order harmonic is equivalent to the sound-field pressure alone, and gives simply mono without directional information. The three spherical harmonics of order 1 are equivalent to the three cartesian components of particle velocity  $v_x$ ,  $v_y$  and  $v_z$ . Higher orders of spherical harmonics represent non-redundant combinations of higher gradients; they are of potential interest for the future but need not be considered for the purpose of current developments.

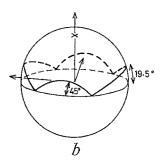

In order to deal properly with indirect sound, which may of course arrive from any direction, a sound-field microphone must encode in a deliberately designed manner any sound reaching it, including sounds having a vertical component of travel. It can be shown that microphones which violate this condition necessarily introduce undesirable coloration into the reproduction of reverberant sounds, even when the vertical information is deliberately suppressed in subsequent processing. From this requirement, having regard to Table 1, it follows that the number of independent signals generated by a microphone should correspond to the square of the natural numbers;  $(n+1)^2 = 1$  giving monophonic reproduction, and  $(n+1)^2 = 4$  the minimum uncoloured reproduction which includes directionality.

	Table 1 Spherical harmonics				
Order 0 1 2 n	No. of harmonics $ \begin{array}{c} 1 \\ 3 \\ 5 \\ 2n+1 \end{array} $	Cumulative total $ \begin{array}{c} 1\\4\\9\\(n+1)^2 \end{array} $			

Gerzon has shown that particular polyhedral arrangements of microphone capsules can fulfil the relevant requirements. The simplest of these places the capsules at the face centres of the regular tetrahedron. The spacing of the capsules should be kept as small as possible, but as it cannot practicably be small compared with the wavelength at higher audio frequencies, correction circuits are needed to compensate for the resultant disturbance between the pressure and velocity responses of the composite microphone. There are some advantages in using a larger polyhedral array to generate a  $(n+1)^2 = 4$  signal, and these are likely to be explored in the future.

The earliest ambisonic experiments were made using an improvised tetrahedral array of ordinary cardioid-response microphones. This arrangement, however, gives rise to considerable mutual interference, and it is impossible to obtain a sufficiently close spacing. Use of microphones in undesigned non-polyhedral arrays, or with spacings of 30 cm or more, or using replay direct into loudspeakers without pressure-velocity compensation, all give markedly sub-optimal results.

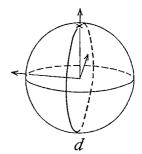

Fig. 2 Some representative horizontal pan-loci. a, Sansui 'QS'; b, closer approximation to great-circle locus consistent with four-channel master tapes (not in commercial use); c, CBS 'SQ'. Note cusps and left-right asymmetry due to choice of front-sector mapping and limitations of encoding from four pair-wise blended channels. C<sub>F</sub>, Centre front; C<sub>B</sub>, centre back; L, full left; R, full right; L<sub>F</sub>, left front; and so on; d, a great-circle locus consistent with ambisonic encoding.

It is desirable to subject the raw signals from the sound-field microphone to a  $4 \times 4$  matrix transformation into a form, call B-format, in which they have reduced sensitivity to small phase or amplitude errors in transmission or recording.

#### Encoding

The problem of encoding of directional information may be stated either in the form of how to make best use of a given number of available channels of communication, or of asking how many channels are necessary and sufficient for a given purpose.

Direction of travel can be characterised by the azimuth angle  $\theta$  and the altitude angle  $(\pi/2-\phi)$ . Both parameters can be encoded on to only two channels carrying signals A and B for example as

$$|\mathbf{B}|/|\mathbf{A}| = \tan(\varphi/2) \tag{1}$$

$$LB - LA = 0 \tag{2}$$

There are of course many other informationally-equivalent forms of these equations. In equation (1),  $\tan(\phi/2)$  is taken in order to avoid the 180° ambiguity that would result from using  $\tan \phi$ .

Equations (1) and (2) can equivalently be regarded as defining polar angles  $\theta$  and  $\phi$  (not necessarily identical with azimuth and altitude) which characterise the relative amplitude and relative phase of signals encoded on to two channels. Any given encoding can then be represented graphically by a point on a sphere, known as the Poincaré or energy sphere³. This graphical representation is extremely useful in enabling the properties of proposed coding schemes to be understood, and it possesses a number of useful mathematical properties. The path on the energy sphere described by the representative point as the azimuth explores the horizontal circle is known as the horizontal pan locus; some representative examples are illustrated in Fig. 2.

There are several advantages in making this locus a great circle, and little or nothing to be gained by deviating from this form. Gerzon has shown that matrixing four pairwise-blended channels onto two channels, as in so-called quadraphony, necessarily gives a pan-locus consisting of four circular arcs intersecting so as to include a total angle of  $\pi$  rad at their corners; it therefore cannot give a great circle locus.

Encodings on to three or more channels can be represented similarly by points on hyper-spheres of appropriate dimensionality, but this is somewhat less useful as an aid to intuition because of the difficulty of graphical representation.

Equations (1) and (2) show that directionality can be completely encoded on to only two channels in the 'direction finding' sense, that is, any direction of arrival can be represented unambiguously. This is evidently necessary, but it is not sufficient, to ensure satisfactory performance of the overall ambisonic system, because it does not of itself ensure that the signal channels can be decoded in the required manner.

### Decoding and psycho-acoustic criteria

An exact replica of the original sound field, in the whole region occupied by the listener's head and up to the highest audible frequencies, would require many thousands of audio channels of communication and is quite impracticable. The closeness of approximation that can be achieved depends both on the number of channels and on the number of loudspeakers that are available.

At frequencies low enough for the human head to be small compared with the wavelength of sound, it is indeed possible to reproduce physically the original sound field. At higher frequencies this is no longer possible, and the best that can be done is to fulfil as many as possible of the psycho-acoustic criteria whereby sound directions are localised. These criteria, in relation to practicable systems, have been established particularly by the work of Gerzon already referred to.

Ambisonic reproduction in which vertical directional information is preserved may be called periphonic, and ambisonic reproduction with only horizontal information pantophonic. Pantophonic reproduction geometrically requires a minimum of three loudspeakers, since the triangle is the minimal figure able to enclose space in a plane. Similarly a minimum of four loudspeakers are geometrically necessary to surround the listener in three dimensions and give periphonic reproduction.

To satisfy the psycho-acoustic criteria sufficiently well, however, the practical minimum is four loudspeakers for pantophonic reproduction and six for periphony. One of the effects of using too few loudspeakers is that the loudspeakers themselves can be heard obtrusively as separate sources in addition to any ambisonic impression. This is closely associated with the 'detent effect' whereby as an actual source of sound moves its reproduced image seems to cling to each loudspeaker before jumping relatively rapidly to the next.

The limitations set by the number of loudspeakers interact with those set by the number of available channels. Qualitatively this is as expected, since the available number of loudspeakers limits the number of constraints available to control the sound field in the listening room, while the number of channels places restrictions on the extent to which these control constraints are independent. If four loudspeakers is taken as the practicable minimum for pantophonic reproduction, this is also in most people's minds at present the economic maximum. It can be shown that the capabilities of four loudspeakers in a planar array can be fully exploited using just three independent channels of audio information. By a happy coincidence, the current system of f.m. stereo broadcasting has sufficient bandwidth to transmit three audio channels. Interestingly, if the attempt is made to feed four loudspeakers from four channels in a non-redundant manner, the result is to enhance the detent effect. It can be shown that similarly four channels are sufficient to feed the minimal number of six loudspeakers required for periphonic reproduction. In general, the number of loudspeakers should

exceed the number of channels, so that it always pays to interpose a decoder between the communication channels and loud-speakers.

The practical outcome is that a two-channel four-loudspeaker pantophonic system can give good directional localisation with fulfilment of the salient psycho-acoustic criteria over a larger area than two-speaker stereo. Under favourable conditions, in surroundings that are acoustically neither too live nor too dead, the area of satisfactory and relaxed listening can fill most of an ordinary domestic room. The chief defect is a relative phase shift of 180° around the azimuth circle, unavoidable in any two-channel system, and the best that can be done is to distribute it in an optimally compromised manner. Current ambisonic decoders provide adjustments to compensate for spherical-wave effects of finite loudspeaker distance, and for non-square loudspeaker layouts.

The use of three channels enables the phase difficulty to be removed, and gives some improvement in the accuracy and stability of directional location. The next step in improving pantophonic reproduction is, as already indicated, to add additional loudspeakers rather than additional channels (which can actually make the results worse). Periphonic reproduction is, in the opinion of some who have heard it, at least as great an advance on pantophonic as the latter is on stereo, or stereo on mono. Three-channel periphonic systems may be possible with compromises not dissimilar to those involved in two-channel pantophonic reproduction. The minimum requirement of six loudspeakers in a non-planar array inhibits commercial interest at present, although periphony may have considerable interest for the future.

Beyond the  $(n+1)^2 = 4$  periphonic system, the next basis is  $(n+1)^2 = 9$ , which is also very much a matter for the future.

### Monophonic and stereophonic compatibility

The introduction of a new system always involves problems of compatibility with what went before. Ambisonic compatibility is therefore essentially a matter of the compatibility of its two-channel realisation with the existing two-channel mono and stereo formats.

Complete aesthetic compatibility is never possible between an old system and a new one providing additional information, as for example between stereo and mono or between colour and monochrome television. Technical compatibility depends on which out of a gamut of informationally equivalent ambisonic codings is employed. For ambisonic playback, these codings are equivalent because there is freedom to design the decoder to match the encoding. Ambisonic encoding can easily be made compatible with either stereo or mono, but not both simultaneously. A compromise is necessary, and the basic cause of this is not any fault in ambisonic encoding, but in the historical accident that the apparently obvious stereo and mono encodings concealed an inherent mutual incompatibility. Essentially, a balance must be struck between some attenuation of rear sources and some phase shift between the two loudspeakers in stereo playback; fortunately this can be done in a fairly harmless way.

Ambisonics is still in the experimental stage. It can be realised using two, three or more channels. The two-channel version has particular interest because of the wide availability of two-channel recording and broadcasting media developed originally for stereo use, and the three-channel version has particular interest in relation to f.m. broadcasting. Ambisonics is a complete system from the pick-up of the original sound field through encoding and decoding to the reconstruction of an approximation to the original sound-field in the listener's home. It therefore requires the simultaneous availability of both hardware and software; that is, of suitable decoders and of recordings or broadcasts on which to use them. None of these are commercially available at the present time, but may become so before very long.

Within the limitations of this article the attempt has been made to outline the basic principles of ambisonics with a minimum

of purely technical detail. Ambisonics is not so much a single system as a family of realisations having in common the attempt to state clear aesthetic and technological aims, to adjust these aims to what is physically and mathematically possible, and then to implement a properly engineered system to fulfil the objectives.

The development has been performed principally by M. Gerzon, J. S. Wright and the author with the help and support of the National Research Development Corporation. The experimental equipment was built mainly in the Research Unit for Instrument Physics of the University of Reading. The help of numerous academic and industrial colleagues is also gratefully acknowledged.

### Statistical physics, particle masses and the cosmological coincidences

J. K. Lawrence\* & G. Szamosi†

A new look at some familiar 'cosmological coincidences' provides a means of 'predicting' appropriate mass values for the elementary particles.

For many years, cosmologists have been intrigued by possibly coincidental relationships between physical constants of the microscopic and cosmic domains1. Examples of these are the approximate equality of such large dimensionless numbers as the ratio of the electromagnetic to the gravitational interaction strengths of particles, the ratio of the size of the Universe to the size of an elementary particle and the square root of the number of particles in the Universe. There has been controversy, not only over the possible meaning of these 'cosmological coincidences', but also over the existence of any meaning at all. Here we would like to show how, by means of simple assumptions about the nature of physical parameters and of the Universe, the cosmological coincidences may be derived in a logically coherent scheme. Equally important, this procedure yields a very reasonable limit for the mass of an elementary particle expressed in terms of fundamental constants. An extension of the procedure leads also to an expression for the fundamental electric charge.

The usual view of elementary particles is that similar particles are absolutely identical—that they have absolutely identical masses, electrical or nuclear interaction strengths, magnetic moments, and so on. A less restrictive view, and one perhaps more in keeping with our views of the physics of the early Universe, might be that the properties of elementary particles are determined stochastically. Thus, some physical parameters of a set of elementary particles, particularly their masses, might not be absolutely identical, but rather form statistical distributions about average values, which depend upon the overall thermal properties of the Universe. According to the usual principles of statistics, the standard deviation of the equilibrium mass would be

$$\delta m/m \approx 1/\sqrt{n} \tag{1}$$

where n is the number of particles in the Universe. Whether n is considered to be the total number of particles in the Universe or the number of a given species, such as electrons or nucleons, is not important within the accuracy considered here. In this same spirit, we regard the (average) masses of all elementary particles to be essentially equal.

#### Variations of mass

We can now further restrict the mass fluctuations, using an anthropocentric argument similar to ones used in the past by

Dicke<sup>2</sup> and Carter in unpublished work. The existence of human life and awareness requires that the Pauli exclusion principle act over cosmological times. The nuclei of the various elements from which we are constructed must have existed for at least the age of the Solar System, and the structure of these nuclei depends on the Pauli principle, which depends on the indistinguishability of protons and of neutrons. If the masses of these nucleons differed by a detectable amount, the particles would no longer be indistinguishable and the Pauli principle would break down. According to quantum mechanics, in the age T of the Universe (or of the Solar System) it is possible to detect a mass difference  $\hbar/c^2T$ . Thus we conclude that the mass spread of elementary particles must be less than this critical value. Then,

$$\delta m \approx \hbar/K_1 c^2 T \tag{2}$$

where  $K_1 > 1$  is a dimensionless constant.

We next make the assumption that the Universe, at least approximately, is just gravitationally bound. This allows us to relate the gravitational constant G, the mass M, the radius Rand the age of the Universe by

$$R \approx cT \approx GM/c^2 \approx Gmn/c^2$$
 (3)

This relationship, sometimes connected with Mach's principle, is roughly compatible with observations and is widely assumed by cosmologists.

It is now possible to combine equations (1), (2) and (3) to obtain an expression for the mass of an elementary particle in terms of fundamental constants: .

$$m \approx (\hbar^2/K_1GcT)^{1/3} \tag{4}$$

Taking  $T \approx 10^{10}$  yr gives the numerical relation

$$m \approx K_1^{-1/3} \times 10^{-25} \,\mathrm{g}$$
 (5)

This gives an upper limit for elementary particle masses which is consistent with the existence of human life in the Universe:

$$m \lesssim 10^{-25} \text{ g} \tag{6}$$

A wide range of values of  $K_1$ , covering many orders of magnitude, will give values of m lying within the range of elementary particle rest masses ( $\sim 10^{-27}$  g to  $\sim 10^{-24}$  g). A recent study by Reines and Sobel3 indicates that the lifetime of the Pauli principle for inner shell electrons in iodine may be  $\sim T \times 10^{10}$  yr. Since the breakdown rate would be proportional to the square

<sup>\*</sup>Department of Physics and Astronomy, California State University, Northridge, California 91324.

<sup>†</sup>Department of Physics, University of Windsor, Windsor, Ontario, N9B 3P4 Canada.

of the perturbation  $\delta m$ , this result implies a value  $K_1 \approx 10^5$  for these particles. This, when substituted into equation (5) implies  $m \simeq 10^{-27}$  g, the electron mass. It would be of great interest to measure the analogous Pauli breakdown rate for heavier particles, such as nuclear protons or neutrons. A value  $K_1 \approx 1$  also gives a mass well within the range of known particle masses, and for convenience we will now adopt this value. It should be kept in mind that both the theory presented here and the corresponding observational results are very rough. Thus large changes in the value of  $K_1$  will have no fundamental effect on any of the following equations.

### Cosmological coincidence

Apparently, Weinberg4 first noted the existence of equation (4) as a numerical coincidence and discussed its possible importance as a clue for a connection between microphysics and the Universe as a whole. The above considerations appear to give a possible rationale for its existence.

If we use  $K_1 \approx 1$  in equation (5), we find  $n \approx 10^{80}$ , which is compatible with present data, and  $\delta m \approx 10^{-65}$  g. By eliminating G from equations (3) and (4), we obtain

$$R/(\hbar/mc) \approx \sqrt{n}$$
 (7)

Elimination of R yields

$$m \approx m_*/n^{1/4} \tag{8}$$

with  $m_{\star} = (\hbar c/G)^{1/2}$ , the Planck mass. Also one finds the gravitational fine structure constant

$$\hbar c/Gm^2 = (e^2/Gm^2)(1/\alpha) \approx \sqrt{n}$$
 (9)

Equations (7) to (9) have often been noted in the literature as the 'cosmological coincidences.'

It is of further interest to consider the effect induced on particle self-energies by the variation  $\delta m$ . By requiring the induced variations in self-energy to remain too small for detection in the age of the Universe, as in the argument leading to equation (2), we obtain constraints on the values of the interaction coupling constants. We consider the formula for the lowest order electromagnetic self-energy of an electron given by Salam et al.5 where the ultraviolet divergence has been removed by inclusion of gravitational self-energy:

$$E \approx (me^2c/\hbar) (\ln n) \tag{10}$$

Requiring the variation induced in this by  $\delta m$  to be undetectable gives for the fine structure constant

$$e^2/\hbar c \approx (K_1/K_2)/(\ln n) \tag{11}$$

Where  $K_2 > 1$  is another dimensionless constant. This result is roughly correct if  $K_2 \approx K_1$ .

### Lightning in astronomy

E. W. Crew\*

The author suggests that evidence for lightning on a grand scale in astronomy is most convincing. It might explain stellar flares, cosmic jets, quasars, galactic evolution, and much more. In this model, electrical charges accumulate in apparently highly conducting atmospheres.

Most of the characteristics of violent and sudden events1 in astronomy can be explained simply in terms of well-established laws of physics if electrical discharges, similar to lightning, occur in the atmosphere of stars and galaxies. This entails the formation and separation of positive and negative charges of sufficient energy to produce electrical breakdown in gases which generally have far greater conductivity than the relatively cold and dense atmosphere of the Earth. Careful examination of the evidence for electrical discharges in astronomy shows, however, that these almost certainly do occur and therefore charging does take place. This was first suggested by C. E. R. Bruce in 1941, following extensive research on laboratory electrical discharges and lightning as a member of the Electrical Research Association.

I do not claim to conform with Bruce's views, but this article should give an indication of the scope and value of the work. Details have been published in many letters in scientific and technical journals, but the description of his theory as a whole, essential for understanding these letters, has had rather limited distribution, mainly in a report with full references<sup>2</sup>, a chapter in a popular science book<sup>3</sup> and a conference publication4.

The study of terrestrial lightning is full of uncertainties because of its unpredictable location and brief duration<sup>5</sup>. The immensely more powerful and prolonged discharges in astro· nomy should help in the understanding of the processes in our atmosphere. The key to many astronomical events is the typical characteristic of an atmospheric discharge: a very rapid rise to maximum current, a steep decline, then a gradual fall over a relatively long period, with in some cases a secondary smaller rise of current, such as occurs in flare stars.

### Solar characteristics

If electrical charges accumulate in the Sun's atmosphere until sudden breakdown occurs, the discharges and induced currents will produce all the high temperatures and ionised conditions which seem to most astronomers to prevent electrical charging. It is therefore advisable to examine more closely how charging could occur, instead of rejecting it on the basis of superficial appearances. The generation of charges is chiefly by the friction of glancing collisions between solid particles or liquid drops, much as in the Earth's atmosphere. Other processes such as splitting during solidifying and unequal size disintegration of drops with induced charges are probably also significant. Particles of high melting point metallic materials are formed at about 3,500 K and have been collected by rockets and Earth satellites7. The diffuse blue rings surrounding sunspots8 are visible evidence of the formation of large numbers of small particles. They must also form in intergranular regions at the base of the photosphere and then be ejected into the upper regions by the violent winds and powerful thermals present.

Smaller particles are segregated from larger because forces

<sup>\*26</sup> St David's Drive, Broxbourne, Hertfordshire, EN10 7LS, UK.

acting on the projected area have greater effect on lighter particles. These generally have a preponderance of negative charge and therefore produce a surplus of negative electricity at high levels in the atmosphere, corresponding to a surplus of positive charge below9. The interactions of ions and free electrons with these particles is complicated, but it is likely that charges accumulate in the highly conducting atmosphere because the positive particles will rapidly capture free electrons. There will then be a surplus of positive ions which are far more massive than electrons and take much longer to neutralise the equivalent negative charge on the smaller particles, enabling the surplus negative charge to accumulate in regions remote from the positive charge zone. Hydrogen and other elements at this location and temperature are far from fully ionised10 and the increasing voltage gradient due to the charges will eventually cause further ionisation, leading to electrical breakdown. The rate of charging will reduce as the voltage gradient increases, but the forces unleashed by solar activity are so immense that ample energy is evidently available for discharge conditions to be attained.

At any given time there are several million electrical discharges in the photospheric region, each about 1,000-2,000 km long and lasting 10 min, causing the average temperature of the solar 'surface' to rise to 6,000 K. The flow of positive ions in the electromagnetically compressed discharge channels persists for a time after the charge is consumed and the hot gas ascends and extends above the extinct arcs, forming the white patches of granulation. Most of the particles are recycled, as in terrestrial meteorology, but some are ejected to greater heights, aided by radiation pressure, carrying charge with them and building up electrical energy in the corona. The resulting discharges are generally more sporadic and violent, such as long prominences, and these are observed to have the same velocity of propagation as terrestrial lightning, attracting other prominences like currents in parallel conductors. The electrical and magnetic influence of these powerful discharges destroy some areas of the photospheric discharges, forming sunspots, in which the magnetic field pattern is the resultant of the surrounding photospheric discharges and that of the flare above. It is unnecessary therefore to assume that magnetic fields are produced by some unknown process inside the Sun, especially as the generally held view, that the magnetic field is always vertical in the umbra of sunspots, has been disproved by observations11.

The discharges in the perimeter of sunspots show as white streaks bent back by electromagnetic attraction towards the surrounding discharges. Jets from these discharges produce the outward flow of gas known as the Evershed effect, and their maximum observed velocity of 8 km s<sup>-1</sup> agrees with Bruce's calculated value<sup>2</sup>. The photograph of a sunspot (Fig. 1) taken

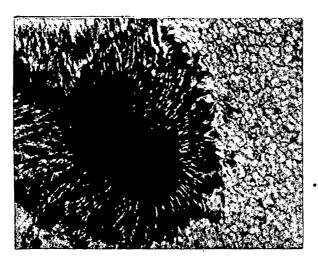

Fig. 1 Sunspot and granulation. (Courtesy Project Stratoscope of Princeton University.)

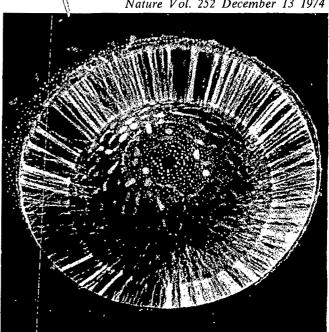

Fig. 2 Annular electrical discharges in a boiler igniter. (Courtesy Colt International Ltd, New Lane, Havant, Hampshire.)

by the Project Stratoscope<sup>12</sup> balloon-mounted telescope clearly shows the white tracks of electrical discharges of a width less than 300 km, the limit of the resolution of the telescope<sup>13</sup>. It is of interest to compare this with the photograph of an annular electrical discharge in a boiler igniter (Fig. 2), which shows several remarkable similarities, considering the enormous difference of scale. Many peripheral sunspot streaks resemble the jets produced by a laboratory plasma projector.

Bruce's theory explains many other solar characteristics in terms of electrical discharges and predicted temperatures of over 108 K in the corona a year before this was confirmed by observations14. He describes many cases of prolonged stellar atmospheric discharges, where the close correlation with observational evidence and similarity to lightning characteristics are most striking. It is an important confirmation of his theory that many planetary nebulae as well as galaxies have straight or spiral arms, evidently formed by discharges in which electromagnetic forces concentrate the matter in their channels. In planetary nebulae this material condenses to form binary partners and planets, while in the vast galactic discharge channels, stars and smaller nebulae are formed. The well known 'ring' type planetary nebula is only one of many different kinds, and if they all evolve in a similar way, then its shape is not that of an expanding shell of gas, but merely the result of a discharge jet happening to be in line, or nearly in line, with the observer. Doppler spectra characteristics show diametrically opposite jets in some of these nebulae.

The theory that solar disturbances are caused mainly by the movements of charged atmospheric particles may explain why the level of activity in the Sun is so closely related to the tidal effects of the planets<sup>15</sup>. Small prominences and certain other solar features seem unlike any discharge process and may be caused by the varying magnetic fields of the large discharges acting on ions and charged particles, particularly when these are near the magnetic focus of deflected current channels.

#### Galactic evolution

If charged particles are ejected or repelled by the hot nucleus of a galaxy for hundreds of millions of years (Hubble stages E0 to E7), a very extended charged atmosphere will develop with an immense store of electrical energy. The galaxy will then be poised on the brink of an enormous atmospheric discharge, in which a small increase in the voltage gradient would start a cataclysmic outburst near the nucleus and the jet would then advance far into the charged atmosphere. The initial main breakdown is likely to be initiated by the gravitational, electrical

or magnetic influence of an active neighbouring galaxy, possibly explaining why some discharge jets appear to point in that direction16. This 'quasar' phase occurs at Hubble stage S0, the point of departure for three types of evolution (Fig. 3). The discharge would very quickly attain peak output lasting for a few million years, during which time a second diametrically opposite discharge would occur, set off either by the extragalactic cause of the original discharge, or as a result of shock waves from the first jet orbiting the nucleus and focusing at the antipodes. Both discharges then continue to extend far into the surrounding negatively charged atmosphere at an average velocity of about 4,000 km s<sup>-1</sup> (ref. 17).

Such a jet, with its myriads of discharge channels (similar to the few that are plainly visible in the great solar flare of June 4, 1946) would engulf a star like the Sun in minutes, heating the entire mass to thermonuclear temperatures and causing the short time variation of energy output which is observed in quasars. Magnetic pinch effects would also produce variations, but over far longer periods, as is evident from the jet of M87. An indication of diametrically opposite jets may be the difference in the values of the red shift of the nucleus, if detectable, which is the cosmological value, and the emission and absorption spectra of the jets, where there is a high relative velocity in line

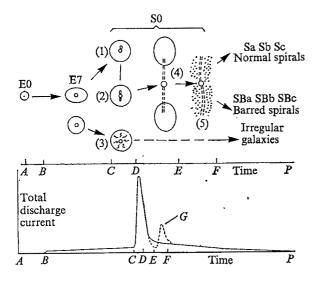

Fig. 3 Galactic evolution by electrical discharge processes. A-C, Long period of slow galactic growth  $(10^9-10^{10} \text{ yr})$  and increasing temperature of its nucleus, which repels charged particles and starts the gradual accumulation of electrical energy. B-C, Atmospheric voltage gradient produces small aggregate leakage current (vertical scale exaggerated) which is limited by the availability of free ions in a very rarified atmosphere. When the maximum value is attained at any particular time and place, the voltage gradient can increase without a corresponding appreciable increase in the leakage current (Townsend effect). The gradient is highest near the nucleus and falls approximately as the inverse cube of the distance (for a distributed charge). C-D, Eventually the increase in the electrical field causes electrons to attain the energy required to produce further ionisation, and catastrophic discharge occurs. This is the quasar phase (1), lasting 106-107 yr. During this time opposite jets form (2). In about 3% of galaxies irregular discharges occur (3). D-E, The extending discharges energise surrounding free electrons to relativistic velocities, which produce radio emission from extensive lobes (4). This is the radio-galaxy phase. E-F, The electrical charge rapidly diminishes and the lobes of radio emission contract. The regions surrounding the discharges cool and clouds of obscuring matter are produced. These absorb the energy of the high temperature core of the discharges and re-emit it as infrared radiation. This is the Seyfert phase (5). F-P, Charge continues to be collected from the galactic atmosphere, but the electro-magnetically compressed discharge channels gradually cool and the matter condenses into the stars and planetary nebulae of the galactic arms. Some galaxies are distorted by impinging extragalactic fields. G, The main discharge may be restricted by the pinch effect, followed by another burst of energy at a lower level. Periodic outbursts (not illustrated) may be caused by repeated charge-discharge processes, helped by the huge forces of the active phase.

with the observer. The magnetic fields of the discharges extend to other galaxies, which frequently show the peculiar shapes caused by the impact of these powerful forces. Perhaps the reversals of terrestrial magnetism and other disturbances in our galaxy are the result of giant discharges in neighbouring galaxies.

The channel of a discharge would acquire a powerful positive charge, causing free electrons in the surrounding atmosphere to accelerate towards it, attaining relativistic velocities in extensive lobes on each side of the nucleus, as the quasar evolves into a radio galaxy (after Ryle<sup>18</sup>). Synchrotron emission by electrons in the extensive magnetic fields of the discharges would contribute to the total radiation. The flow of current following the characteristically 'brief' peak period of a few million years would be maintained by the collapsing magnetic field and the slower lateral current infeed from the surrounding charged zones. In straight discharges, matter from the jets then accumulates near the ends of the arms, as seen in NGC2859, but in discharges which are deflected by the field of adjacent galaxies or by rotation, the ejected matter continues in orbit about the nucleus, forming spiral arms. The intermediate Seyfert stage is illustrated in Fig. 3. A few cases are known where the spiral structure has apparently been formed by tidal forces. If random major discharges occur in the absence of a single main initial discharge due to an external influence or rotation, an irregular galaxy is formed.

The energy produced by the discharges is largely from thermonuclear reactions caused by high temperatures and electromagnetically increased pressures. No other known processes in astronomy can account adequately for the extent of nuclear synthesis required19. The energy was estimated by Bruce as 1060 to 1061 erg (ref. 2) on the basis of mass loss, which compared well with later estimates by others involving radiation measurements20. As in the stellar cases, many theoretical deductions by Bruce were confirmed by observations2. He has gone on to conjecture that strings of galaxies were formed as condensations in the universal discharge channels of the original Big Flash, and to predict that these galaxies have a higher content of heavy elements after their long subjection to thermonuclear reactions, compared with galaxies formed more slowly by gravitational aggregation outside the discharge channels.

### Validity of theory

Although in recent years many astronomers have suggested the time is ripe for a revolutionary new approach to clear up the many problems in astrophysics, few have commented on Bruce's work, presumably because it cannot be properly understood without some knowledge of the characteristics of lightning and other electrical discharges. Bruce was in the unusual and fortunate position of having studied these subjects intensively, his publications earning him a DSc. He then concentrated on the applications to astronomy, and was able to do this without preconceived ideas. His position outside the accepted astronomical organisations has, however, made it more difficult for his views to become widely known. One objection is that his theory is not supported by any detailed mathematical studies, but until it is better known and understood, these are unlikely to be attempted.

Perhaps this article will encourage workers in many fields of astrophysics to take a closer look at Bruce's work and to develop it in greater detail. If they will start by assuming it is possible for electrical charging and discharging to take place, then see where this will lead, perhaps the validity of their assumption would soon be established and C. E. R. Bruce would obtain the recognition he deserves.

### The coenzyme-binding domains of glutamate dehydrogenases

John C. Wootton

Department of Genetics, University of Leeds, Leeds LS2 9JT, UK

A combination of secondary structure predictions and sequence comparisons with dehydrogenases of known structure allows two coenzyme-binding domains to be located in each of the sequences of bovine and Neurospora glutamate dehydrogenases. One domain shows significant sequence homology with the structurally-similar domain of glyceraldehyde-3-phosphate dehydrogenase.

Amino acid sequences of three glutamate dehydrogenases (GDHs) have been determined: the bovine liver (500 residues) and chicken liver<sup>2</sup> (503 residues) enzymes, and recently the NADP-dependent enzyme from the fungus Neurospora crassa³ (452 residues). All three are hexamers of identical subunits. Bovine and chicken GDHs are strongly homologous, differing only in 30 residues<sup>2</sup>, and although bovine GDH will be considered here the conclusions apply equally to the chicken enzyme. The Neurospora enzyme shows clear but limited homology with the vertebrate GDHs in the N-terminal two-thirds of the chain<sup>3,4</sup>, suggesting that the fungal and vertebrate enzymes shared a common evolutionary origin. The Neurospora GDH differs from the vertebrate enzymes in allosteric properties and in being NADP dependent. Vertebrate GDHs can utilise either NAD or NADP. Like many other microorganisms, Neurospora has a distinct NAD-dependent GDH which will not be considered here.

Knowledge of the three-dimensional structure of these enzymes is desirable but a crystallographic structure determination of any GDH is very remote. Large crystals and preliminary diffraction data have been obtained for the Neurospora enzyme (I. D. A. Swan, A. C. T. North and J. C. W., unpublished) but the crystal form examined had a large asymmetric unit and complex unit cell. As an interim measure I report here predictions of secondary structure in GDHs and sequence comparisons with other dehydrogenases of known structure. Taken together these two approaches allow the clear identification in each of the bovine and Neurospora GDH sequences of two structural domains (termed domain-1 and domain-3 because of their

positions in the sequence) which resemble the coenzyme-binding domains of other dehydrogenases.

The NAD-binding domains are of very similar structure in lactate dehydrogenase<sup>5</sup> (LDH), soluble malate dehydrogenase<sup>6</sup>, liver alcohol dehydrogenase7 (ADH) and muscle glyceraldehyde-3-phosphate dehydrogenase8 (GPD) and an analogous domain binds ATP in phosphoglycerate kinase9,10. A description and schematic diagram of this common domain is given by Rossman et al.11. In different enzymes it varies between about 110 and 160 residues and contains a central six-stranded parallel β sheet. The  $\beta$  strands in their order in the sequence are termed  $\beta A$ ,  $\beta B$ ,  $\beta$ C,  $\beta$ D,  $\beta$ E and  $\beta$ F. The strand order in the  $\beta$  sheet in the above enzymes is CBADEF. The β strands are interconnected by more variable loops containing α helices and in some cases β structure (Fig. 1). The ABC half of the domain is related to the DEF half by an approximate twofold axis, and each half has been termed a mononucleotide binding unit11. Domains with central parallel  $\beta$  sheet, some of which also have a nucleotide-binding function, have been described in other proteins11, but these differ from the dehydrogenase domains in the number or order of the  $\beta$  strands. Rossman et al.11 propose that all these domains share a remote common ancestor in precellular evolution.

Secondary structure predictions

Of several available methods<sup>12-16</sup> for predicting the positions in protein sequence of  $\alpha$  helices and  $\beta$  structure, I have used the method of Chou and Fasman<sup>12,13</sup> which derives separate rules for the nucleation and stability of  $\alpha$  and  $\beta$  structures from the frequency of occurrence of residues in these structures in 17 proteins. In a comparison of several prediction methods applied to the parallel β sheet domain of adenylate kinase<sup>17</sup>, this method was as successful as any and compared well with the pooled results of the different methods. I have tested the applicability of the method to parallel \beta sheet domains by making predictions for the domains of known structure in ADH, GPD and LDH (Fig. 1), and by comparison of the number of residues found in the parallel \beta strands of six proteins with the numbers expected from the  $\beta$  potentials of Chou and Fasman<sup>12,13</sup> (Table 1). To simplify my report, predictions of bends will be omitted because they do not significantly affect the proposals for the GDHs.

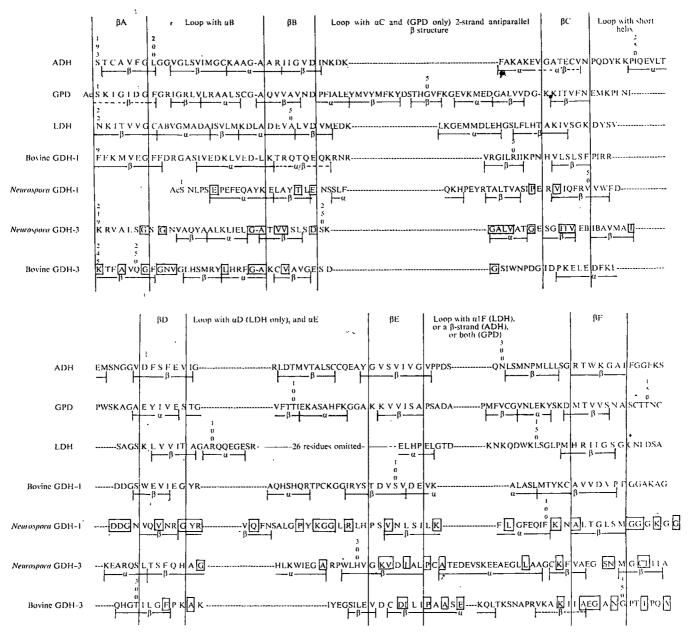

Fig. 1 Alignment of coenzyme-binding domains. The sequences (in one-letter code<sup>18</sup>) are of horse liver ADH (ref. 27), lobster muscle GPD (ref. 28), dog-fish M<sub>4</sub> LDH (ref. 19), bovine liver GDH (ref. 1) and Neurospora NADP-dependent GDH (ref. 3). In the LDH sequence, 26 residues (not included in ref. 19) are omitted because different published versions conflict<sup>11,15</sup>. Except for some loop sequences the alignments of ADH, GPD and LDH are taken from ref. 11. Predictions of  $\alpha$ -helix and  $\beta$ -structure are indicated beneath each sequence. Dashed lines indicate ambiguities or tentative predictions (see text). Boxed residues emphasise the following sequence identities: in Neurospora GDH domain-1 with bovine GDH domain-1; in Neurospora GDH domain-3 with GPD; in bovine GDH domain-3 with Neurospora GDH domain-3. Precise residue-by-residue alignment can be deduced by counting residues from the nearest vertical line.
\* Reactive residues.

The overall frequencies of residues in parallel β sheets (Table 1) agree very well with expectation, the only significant deviations being an excess of asparagine (and perhaps also of valine and isoleucine) and deficiencies of glutamine and methionine. The distribution of residues along parallel β strands in these six proteins shows tendencies for lysine to favour the N-terminal ends and for glutamate and aspartate to favour the C-terminal ends. If the published  $\beta$  potentials<sup>12,13</sup> for lysine, glutamine, asparagine, glutamate and aspartate are modified to accommodate these discrepancies and tendencies, however, no β-prediction for the domains of ADH, GPD and LDH is altered by more than two residues. Therefore I have used the published β potentials without modification, taking—where given—the values based on 17 proteins13 rather than those based on 15 (ref. 12).

I have also tried a less demanding nucleation condition to take into account the excess of valine and isoleucine: that any two of valine and isoleucine out of three residues is a possible

 $\beta$  nucleus. This condition permits  $\beta$  predictions approximately corresponding to BA of GPD and to the putative BF of bovine GDH domain-3, which are not otherwise predicted as  $\beta$  strands, but this condition should not be applied generally without further tests. Predictions using this rule, and two ambiguous predictions, are indicated by dashed lines (in Fig. 1). The ambiguities arise in cases where two almost completelyoverlapping sets of residues have high and almost equal average α and β potentials. In other cases where predictions of high  $\alpha$  and  $\beta$  potential overlap, the residues have been resolved into an a section (minimum lengths six residues) and an adjacent β section (minimum length five residues) provided these sections are individually consistent with the rules of Chou and Fasman<sup>13</sup>. The rules are somewhat ambiguous in defining the ends of a and β sections and in some predictions in Fig. 1 up to two end residues could be added or subtracted arbitrarily.

The assignments for ADH, GPD and LDH (Fig. 1) show that the method is largely successful in predicting the approximate,

Table 1 Comparison of the numbers of residues observed in the parallel  $\beta$  strands of six proteins with the numbers expected from the  $\beta$  potentials of Chou and Fasman<sup>12,13</sup>

	Summed composition	Number of residues found	Expected
	of the six proteins	in parallel β sheet	number
Ala	140	19	18.8
Arg	41 •	4	5.1
Asn	51	10	5.3
Asp	84	9	9.3

Val	169	47 .	38.5
Total	1,584	226	226.1

The proteins, and the references to the structural information, are horse liver ADH<sup>7,27</sup>, lobster muscle GPD<sup>8,28</sup>, dogfish M<sub>4</sub> LDH<sup>5,19</sup>, porcine adenylate kinase<sup>21</sup>, *Peptostreptococcus elsdenii* flavodoxin<sup>32</sup> (aligned by homology with the *Clostridium* MP protein alignment<sup>11</sup>), and subtilisin Novo<sup>32</sup>. The expected numbers are calculated as described by Chou and Fasman<sup>12</sup>, using the summed amino-acid compositions of the six proteins (first column).

positions of  $\alpha$  and  $\beta$  sections, although the ends of the predicted sections are usually inaccurate by a few residues. Of the 18 ß strands in the parallel sheets the approximate positions for 14 (or 15 if the specific nucleation condition is used) are successfully predicted. Of the remaining three  $\beta$  strands,  $\beta$ C of ADH has an ambiguous rather than an incorrect assignment, and βD of GPD, although predicted as α helix in the lobster sequence (Fig. 1) is predicted as  $\beta$  in the homologous pig and yeast enzymes. In the loops between the  $\beta$  strands many predictions are approximately correct, but in several cases part or all of some  $\alpha$  helices, particularly  $\alpha B$  and  $\alpha E$ , are predicted as  $\beta$ . The consistent occurrence of this type of incorrect prediction is interesting because it suggests that the stability of some of the a helices may depend on long range constraints involving parts of the domain which are remote in the sequence. The general success of this and other prediction methods<sup>13,15</sup> is dependent on most secondary structure in the proteins being determined by short range interactions.

#### Alignment of the GDH domains

Application of secondary structure predictions to the bovine and Neurospora GDH sequences revealed two candidates in each sequence for parallel  $\beta$  sheet domains. These resemble the known coenzyme-binding domains in being 100-150 residues long, very rich in secondary structure with a tendency for  $\alpha$  and  $\beta$  sections to alternate, in having candidates for bends only near the ends of  $\alpha$  and  $\beta$  sections and in the absence of long sections predicted as random coil. Secondary structure patterns of this type are not in themselves definitive of parallel β sheet domains because they could perhaps arise by chance or from other types of structure. Confidence in the conclusion that these parts of GDH are coenzyme-binding domains comes from the occurrence at approximately the correct positions of critical residues which are functionally important in coenzyme binding in other dehydrogenases11, and in the case of domain-3 from sequence homologies with the GPD domain.

The critical residues<sup>11</sup> used as criteria of alignment of the GDH domains are (Fig. 1, numbered for ADH), glycine 199, glycine 204 (conservatively replaced by alanine in *Neurospora* GDH domain-3), aspartate 223 (conservatively replaced by

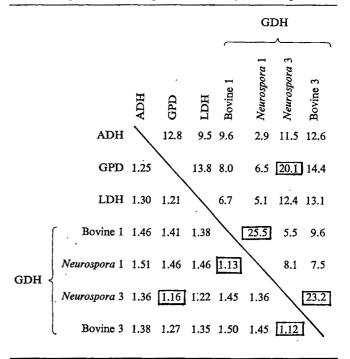

glutamate in three of the GDH domains), and one or other of glycine 261 or glycine 270. Also used are the hydrophobic residues which occur in most but not all cases at the third and fifth positions from the N-terminus of each of the parallel  $\beta$  strands<sup>11</sup>.

Approximate alignments of the GDH domains were initially based on tentative identifications of the six parallel  $\beta$  strands from the secondary structure predictions, using the following criteria of the lengths of loops between the parallel  $\beta$  strands. First, the  $\alpha B$  loop is always 17 or 18 residues; second, the  $\beta C$  to  $\beta D$  loop is not shorter than 8 residues, as in LDH; third, no other loop is shorter than 10 residues. Twelve residues in the  $\alpha C$  loop of ADH is the shortest other loop of known structure, but ten-residue loops are structurally plausible.

Surprisingly, in the case of bovine GDH domain-1 only one approximate alignment was consistent with both the secondary structure predictions and the loop criteria, and this was slightly refined to align critical and hydrophobic residues, giving the alignment shown in Fig. 1. In this domain the  $\beta$ C,  $\beta$ E and  $\beta$ F regions may be inaccurate by a few residues, but no grossly-different alternatives satisfy the criteria. Minor adjustments could slightly increase the sequence similarities to ADH or GPD but at present these are not justified. *Neurospora* GDH domain-1 was aligned by sequence homology with bovine GDH domain-1. It lacks a candidate for the  $\beta$ A region but otherwise satisfies all the criteria well (Fig. 1).

In the case of domain-3 of both GDHs, several alternative approximate alignments, differing in the lengths of the loops, were equally consistent with the secondary structure predictions and loop criteria. Fortunately one of these alignments of *Neurospora* GDH showed sequence homology with the domains of the three GPD sequences, and the same alignment also conserved the critical and hydrophobic residues. These criteria give considerable confidence that this alignment of *Neurospora* GDH domain-3 (Fig. 1) is essentially correct, the only uncertainty

Table 2 Sequence relationships between coenzyme-binding domains

Pairwise comparisons of the alignments in Fig. 1 are expressed as (upper right of matrix) number of identical residues per 100 residues compared, and (lower left of matrix) minimum base changes per codon compared. Numbers for GPD are the average of the three comparisons with the lobster muscle<sup>28</sup>, pig muscle<sup>29</sup> and yeast<sup>30</sup> sequences, the latter two being unambiguously aligned by homology with the lobster GPD alignment in Fig. 1. Boxes enclose the comparisons showing strongly significant relatedness.

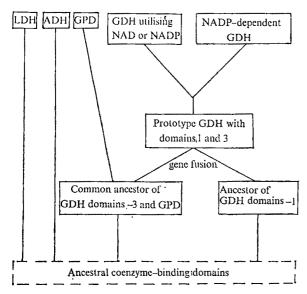

Fig. 2 A model of the early evolution of glutamate dehydrogenases.

being the exact location of the  $\beta D$  region where the sequence homology is weakest. Bovine GDH domain-3 was aligned by sequence homology with this *Neurospora* domain, and its alignment (Fig. 1) also conserves the critical and hydrophobic residues. The sequence identities in these alignments are emphasised by boxes in Fig. 1.

Part of bovine GDH domain-3 ( $\beta$ A to  $\beta$ B) was identified and aligned by Rossman *et al.*<sup>11</sup> on the basis of the sequence homology with GPD in this region, which includes the conservation of critical residues. In the bovine case this homology does not extend markedly to the rest of the domain. My arguments demonstrate that conclusions based on weak sequence homology can be considerably strengthened by secondary structure predictions which may in favourable cases provide a rational basis for the assignment of gaps to appropriate parts (such as loops) of sequence alignments.

#### **GDH** domains and enzymology

Direct coenzyme-binding measurements<sup>20,21</sup> suggest that bovine GDH has two coenzyme-binding sites per polypeptide chain, one involved in enzyme activity with a high affinity for both NADH and NADPH, and the other of low affinity for NADH and very low affinity for NADPH. Similar measurements on Neurospora GDH (ref. 22 and B. Ashby, J. C. W., and J. R. S. Fincham, unpublished) have shown a stoichiometry of one molecule of NADPH bound per polypeptide chain in the conditions tried, but the inactivation of this enzyme by NADPH<sup>23</sup> is perhaps consistent with the presence of a second NADPH-binding site.

The alignment of domain-1 of the GDHs unexpectedly located the reactive lysine (126 in bovine, 113 in Neurospora) in the bend sequence immediately following BF (Fig. 1). In both enzymes<sup>24-26</sup> this lysine has an abnormally low pK and is highly reactive to pyridoxal-5'-phosphate. Modification of the lysine inactivates the enzyme and bound coenzyme protects against this inactivation. The reactive cysteines of LDH and GPD are in closely equivalent locations (Fig. 1), which places the reactive group close to the nicotinamide end of the bound coenzyme. In the equivalent bend of ADH lysine 323 occurs in a sequence similar to that of lysine 126 of bovine GDH (-Phe-Gly-Gly-X-Lys-). ADH lysine 323 is not known to be reactive. The reactive lysines of GDH could have either a catalytic role (as suggested for cysteine 148 of GPD (ref. 8)) or a location in which modification sterically interferes with coenzyme binding (as suggested for cysteine 164 of LDH5).

If GDH is analogous to LDH and GPD in the structural

relationship of the reactive residue to coenzyme binding, it follows that domain-1 is the site involved in activity. The alternative possibility cannot be excluded: that domain-3 is the site involved in activity and that the reactive lysine projects into domain-3 so that its modification interferes with coenzyme binding.

Although *Neurospora* GDH domain-1 lacks a sequence for  $\beta A$  and is most simply interpreted as a five-stranded  $\beta$  sheet domain, it is a good candidate for an NADP-specific binding site. Current evidence suggests that in this *Neurospora* GDH, the primary interaction in coenzyme-binding is with the 2'-phosphate of the adenosine ribose. NADH binding is not detectable (ref. 22 and B. Ashby, unpublished). 2'-AMP, but not 5'-AMP, is an inhibitor showing competitive kinetics with NADP (ref. 22), but the relatively low affinity for 2'-AMP suggests that interactions at the nicotinamide end of the coenzyme are also involved. It is possible that  $\beta A$ , which interacts with the adenosine ribose in NAD-binding domains, is dispensable in NADP-specific domains.

The putative domain-2, consisting of the sequence between domain-1 and domain-3, is the candidate for the functions of catalysis and 2-oxoglutarate or L-glutamate binding. It shows a slightly greater degree of sequence homology between bovine and *Neurospora* GDHs (ref. 3) than do domains 1 and 3. The possible domain-4, comprising the sequence from domain-3 to the C-terminus of the protein, shows no sequence homology and is completely different in secondary structure predictions in the bovine and *Neurospora* enzymes.

### **Evolutionary implications**

Table 2 shows the sequence relationships between the coenzyme binding domains aligned as in Fig. 1, expressed both as percentage of identical residues and as minimum base changes per codon. On either criterion three comparisons show a strongly significant genetic relatedness which provides evidence for a common evolutionary origin of the two sequences compared: bovine GDH domain-1 with Neurospora GDH domain-1, bovine GDH domain-3 with Neurospora GDH domain-3, and Neurospora GDH domain-3 with the domains of the three GPD sequences. Remarkably, Neurospora GDH domain-3 is almost as closely related to the GPD domains as it is to bovine GDH domain-3. The relatedness of bovine GDH domain-3 to the GPD domains appears much less strong because the homology is mainly restricted to the  $\beta A$  to  $\beta B$  region of the domain. The homologies between GDH and GPD suggest that the lines leading to the vertebrate and the NADP-dependent fungal GDHs diverged from each other very early in evolution, possibly at a precellular stage. A model for the precellular evolution of GDH is proposed (Fig. 2) in which domain-1 and domain-3 occurred initially on separate evolutionary lines and later joined by gene fusion at or after the time of divergence of GDH domain-3 from GPD.

Weakly significant relatedness also occurs between Neurospora GDH domain-3 and LDH, ADH and GPD, and LDH and GPD. This probably reflects a remote precellular common ancestry of all these domains<sup>11</sup>. Caution is required in the interpretation of weak sequence similarities because it is not known to what extent strong structural constraints on sets of residues can result in convergent evolution in different lines. Bovine and Neurospora GDHs domain-1, although strongly related to each other, are not significantly related to any of the other domains. This may reflect detailed faults in the alignments of Fig. 1, if these are out of phase in places with the true evolutionary alignments. Alternatively GDH domain-1 may have accepted mutations at a faster rate than other domains during the evolution of the utilisation of NADP.

### Comparison of classical and autogenous systems of regulation in inducible operons

### Michael A. Savageau

Department of Microbiology, University of Michigan, Ann Arbor, Michigan 48104

The mechanism of autogenous regulation, whereby a protein directly controls the expression of its own structural gene, is compared on the basis of function with the classical mechanism, in which the structural gene of the regulator is itself unregulated. The autogenous mechanism is superior to the classical one in inducible catabolic systems governed by a repressor; the opposite is true if the regulator is an activator.

CONTROL of transcription by a constitutively synthesised repressor protein is central to Jacob and Monod's model for the regulation of gene expression. Inducible operons were the first to be understood at this level of molecular detail in bacteria, and in several of the best studied examples, such as the lactose<sup>2</sup>, galactose<sup>3</sup> and glycerol<sup>4</sup> operons, the classical Jacob-Monod mechanism is believed to be operative. Alternatives, however, have been discovered: the regulator protein in some cases—such as the arabinose5, maltose6 and Dserine deaminase7 operons—is an activator, or positive element, in the control system. In other cases, for example, the histidine utilisation system<sup>8</sup>, there is a repressor mechanism but the regulator protein is directly involved in modulating the expression of its own structural gene. This latter feature of the hut system provides an example of a more general class of phenomena that has been called autogenous regulation9.

What are the functional implications of these differences? The relative merits of genetic control by repressors and activators have been explored elsewhere<sup>10</sup>. Here I shall examine the functional implications of control by a constitutively synthesised regulator and by an autogenously regulated one. To answer questions of this type one cannot compare directly two representative systems (for example, lac and hut) because they have numerous differences that are irrelevant to the comparison of classical

and autogenous regulation per se. A controlled comparison in which the two systems are identical in every respect except for the difference in regulatory mechanism is desirable but difficult to achieve experimentally. Nevertheless, such comparisons can be simulated by mathematical analysis. I have performed such an analysis comparing models of classical and autogenous regulation in inducible operons11. Before discussing the results I shall point out the criteria for functional effectiveness that I have used in comparing these systems.

### Criteria for functional effectiveness

To be specific, I will consider inducible catabolic systems in bacteria that allow the cell to utilise nutrients found in its environment. Several criteria can be formulated for functional effectiveness. (1) A sharp threshold in the concentration of the substrate necessary for induction protects the organism from wasteful synthesis of the catabolic enzymes when the substrate level is so low that insufficient benefit would be gained from induction. (2) The ability to make the most product available to the organism from a given supra-threshold increment in substrate is clearly advantageous to the organism whenever that substrate is the only nutrient available for growth. (3) Stability is obviously essential for a system to function properly. (4) A temporally responsive system can be induced rapidly, which is an advantage when substrate levels change abruptly. (5) Insensitivity to perturbations in the system's component parts ensures that the system will continue to function in spite of the continual perturbations it experiences in any real environment. These perturbations result from non-lethal mutations as well as physical changes in temperature and so on. None of these criteria assumes anything about the type of regulatory mechanism involved.

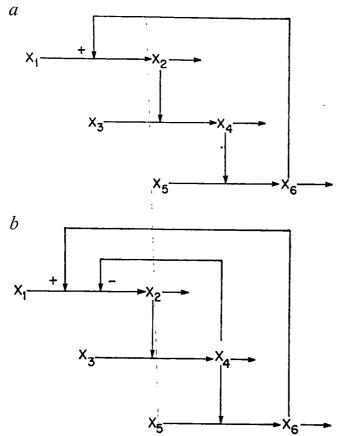

Fig. 1 Schematic models of inducible catabolic systems. a, Classically regulated operon in which the structural gene of the regulator protein lies outside the operon and is regulated independently of the operon. b, Autogenously regulated operon in which the structural gene of the regulator is located within the transcriptional unit that the regulator controls.  $X_1$ , Nucleotide precursors;  $X_2$ , specific mRNA;  $X_3$ , amino acid precursors;  $X_4$ , enzymes of the catabolic pathway (plus regulator in the case of autogenous regulation);  $X_5$ , substrate;  $X_6$ , product-inducer. Although it is not critical for the comparisons reported here, the product has been chosen as inducer because in most cases the inducer is known to be a metabolic product rather than the substrate of the pathway<sup>12</sup>. The horizontal arrows indicate chemical transformations at the mRNA, enzyme and metabolite levels. The vertical arrows represent modifier or catalytic influences (the sense of the influence is positive unless otherwise indicated). Except for the differences in regulation these models are assumed to be identical.

### Comparison of repressor-controlled systems

First, I will compare inducible systems involving repressors that are regulated in the classical manner with those that are regulated autogenously. The two possibilities are represented schematically in Fig. 1. Except for the differences in regulation these models are assumed to be identical.

These two models can be compared under various conditions, and because there are several criteria to consider, a meaningful tabulation of all the results can present a problem. Figure 2, however, is a simple diagram summarising many of the results of these comparisons. This is a two-dimensional plot with the vertical axis representing the strength of the inducer's contribution to the control of transcription and the horizontal axis representing the strength of the autogenous contribution. Each point in this space can be thought of as representing a different system with distinct properties. This space, however, can be divided into subclasses of systems that have similar properties. Since I am comparing inducible systems that utilise a repressor mechanism, the inducer has a positive effect on transcription (g<sub>2d</sub>>0) while the autogenous effect is negative (g<sub>24</sub><0).

Thus, I can restrict my attention to the upper left-hand quadrant of this figure. The vertical axis in this quadrant is the locus of points representing classical systems, since the autogenous contribution is zero. Line (a) represents another classification. The position of this line is determined by analysing the stability of these models. All systems represented by points below line (a) are stable (if perturbed momentarily they will return to their predisturbance condition) whereas all those above this line are unstable (they will not return to their predisturbance condition).

Lines, such as (b), radiating from the point where line (a) intersects the horizontal axis, are lines of equivalence with respect to the first two criteria. All systems whose regulatory parameters have values that determine points on a given line, such as (b), have in common: (1) the same sharpness of threshold in substrate concentration for induction and (2) the same product formation for a given increment in substrate. The slope of the line is a quantitative measure of these properties. The steeper the slope is, the sharper will be the threshold and the greater the product formation.

Systems of the two types now can be compared. As noted before, all of the systems represented on a given line such as (b) behave identically according to the first two criteria. They differ, however, according to the third criterion. The position of the classical system is closer to the boundary of instability than are those of the corresponding autogenous systems represented in Fig. 2. In other words, line (b) and the boundary of instability, line (a), diverge to the left and the autogenous systems lying further from this boundary are more stable.

The fourth criterion, that of temporal responsiveness, is examined in Fig. 3. Curve (a) represents the response of the classical system. The system is in a steady state before t=0. At time zero the substrate concentration is suddenly increased to a new value that is maintained throughout the experiment. The concentration of the product is plotted as a function of time. Similar responses are plotted for a series

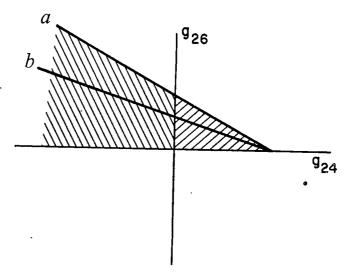

Fig. 2 Graphical comparison of systems with alternative types of regulation. The vertical axis represents the strength of the product's contribution to the regulation of transcription and the horizontal axis represents the strength of the autogenous contribution to this regulation. Line (a) represents the boundary of instability. Line (b) is a representative line of equivalence with respect to the first two criteria for functional effectiveness. The vertical axis is the locus of points representing the classically regulated systems with either activator or repressor control. The shaded area to the left of this axis is the location of points representing stable systems with autogenously regulated repressors. Similarly, the shaded area to the right of the vertical axis represents stable systems with autogenously regulated activators. See text for further discussion.

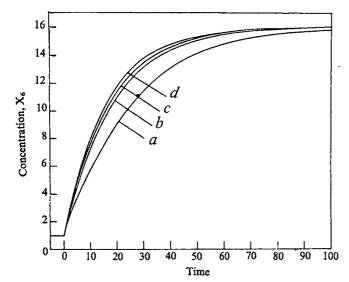

Fig. 3 Temporal responsiveness of equivalent systems with different strengths of autogenous regulation of repressor. The strength is represented by the parameter  $g_{24}$ , which has values: a, 0.0; b, -0.5; c, -1.0; d, -2.0. The corresponding values for the parameter  $g_{26}$  are chosen so that the points representing the different systems all lie on the same line of equivalence. Curve (a) represents the classical system with constitutively synthesised repressor. See text for further discussion.

of systems with increasing strengths of autogenous regulation and represented by points on the same line of equivalence (see Fig. 2). Systems with a high degree of stability tend to have more sluggish temporal responses to change. Figure 3 shows that the opposite relationship is true of systems with autogenous regulation of repressor.

Finally, a comparison on the basis of the fifth criterion shows that the sensitivities of the system with autogenous regulation of repressor to various perturbations in the structure of the system itself are always less than or equal to the coresponding sensitivities of the classical system.

These comparisons show that the autogenously regulated systems are equivalent or superior to the corresponding classical system according to all five criteria for functional effectiveness of an inducible catabolic pathway.

### Comparison of activator-controlled systems

Quite different results are obtained when classical and autogenous regulation are compared in systems governed by an activator protein. Schematic models representing these two types of systems are identical to those in Fig. 1, except that the negative sign is now positive, to indicate that the regulatory protein X4 has a positive effect on the transcription process. Again, except for the differences in regulation these models are assumed to be identical. The functions of these two models can be compared as in the previous section. Since the autogenous effect on transcription is now positive, I will restrict my attention to the upper right-hand quadrant in Fig. 2. The classical systems are represented along the vertical axis with zero autogenous contribution. Line (a) is the boundary of instability, so the stable systems of physiological interest here are represented by points within the shaded triangular area.

All systems represented on a line of equivalence such as (b) are equivalent with respect to the first two criteria. Since lines of equivalence, such as (b), and the boundary of instability, line (a), converge to the right, systems with increasing strength of autogenous regulation are represented nearer the boundary of instability than the corresponding classical system. Systems with autogenous regulation also

show a more sluggish temporal response to change, as Fig. 4 shows. Curve (a) represents the response of the classical system to an increase in substrate. The temporal responses are slower for the corresponding systems with increasing strengths of autogenous regulation (curves b and c). Finally, a comparison on the basis of the fifth criterion shows that the sensitivities of the system with autogenous regulation of activator are always greater than or equal to those of the corresponding classical system.

Thus, the results in this section are the opposite of those previously obtained for systems governed by a repressor protein. According to all five criteria for functional effectiveness, the classical system is equivalent or superior to the corresponding autogenously regulated systems.

#### **Predictions and observations**

The functional differences I have discussed have obvious implications for the natural selection of classical and autogenous mechanisms of regulation in simple, inducible catabolic systems of the type represented in Fig. 1. Systems governed by an activator protein are not expected to utilise autogenous regulation. Activator-controlled systems without such regulation are superior to autogenously regulated but otherwise equivalent systems by all the criteria given for functional effectiveness. On the other hand, systems governed by a repressor protein can be predicted to involve autogenous regulation as well. Systems with autogenously regulated repressor are superior to classical but otherwise equivalent systems by all of these same criteria. How well do these predictions agree with experimental observations?

The first prediction agrees with what is known about activator-controlled systems in enteric bacteria. There is no known instance of autogenous regulation in such systems. In the best studied cases, the arabinose<sup>3</sup> and maltose<sup>6</sup> operons, the structural gene for the activator is located outside the transcriptional unit(s) known to be under its control. [The regulator protein of the ara operon is both an activator and a repressor. However, the predominant functional properties are those of an activator, and for our purposes the ara operon can be considered a (modified) activator-controlled system.] Thus, a simple, autogenously regulated operon is excluded. One could, of course, postulate more complex models of autogenous regulation in

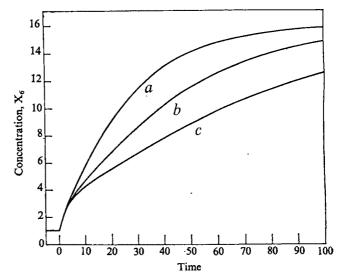

Fig. 4 Temporal responsiveness of equivalent systems with different strengths of autogenous regulation of activator. The strength is represented by the parameter  $g_{24}$ , which has values: a, 0.00; b, 0.15; c, 0.20. The corresponding values for the parameter  $g_{26}$  are chosen so that the points representing the different systems all lie on the same line of equivalence. Curve (a) represents the system with constitutively synthesised activator. See text for further discussion.

which the activator itself is autogenously regulated and its level varies with the expression of the structural genes in another transcriptional unit under its control. Functionally, this type of regulon model would be indistinguishable in most respects from the simple model in Fig. 1b. There is no evidence, however, to support or reject such a model.

The second prediction, concerning repressor-controlled systems, agrees only partially with available evidence. For the histidine utilisation system in Salmonella typhimurium, the evidence clearly agrees with the prediction of autogenous regulation. The structural gene for its repressor is located within one of the transcriptional units controlled by the repressor8. The expression of the second unit also varies with the level of the repressor13, which is functionally equivalent to autogenous regulation for most purposes, as previously indicated. There is no evidence for autogenous regulation in the other two well-studied repressor-controlled systems, the lactose<sup>2</sup> and galactose<sup>3</sup> operons. In each case, the structural gene for the repressor lies outside the only transcriptional unit known to be under its control, so that simple autogenous regulation appears to be excluded. This discrepancy might be explained in one of two ways. The systems might be regulated in a way that is functionally equivalent to autogenous regulation (one possibility has already been mentioned). Alternatively, the systems might have additional, as yet unknown, functions that are not reflected in the criteria for functional effectiveness and that require that the repressor not be autogenously regulated. The first explanation indicates that information about the molecular mechanisms is incomplete, while the second implies a lack of information about the physiological functions of these operons.

With regard to this last possibility, it is already clear that the gal operon is also a component of a much more complex system involved in the biosynthesis of capsular polysaccharide14. Recent evidence indicates that this operon is under the control of two repressors, specified by the galR and capR genes, respectively18. Thus, it would seem that the gal operon cannot be considered functionally as a simple, inducible catabolic system. Similarly, the lac operon

might yet be implicated in additional (dispensible) functions, possibly through the expression of the gene for the transacetylase enzyme, the function of which is presently unknown16.

It has been shown that autogenous regulation has certain advantages and disadvantages and that these have obvious implications for the natural selection of control mechanisms in inducible operons. There is reasonably good agreement of these predictions based on simple models of inducible catabolic systems with current observations of such operons in enteric bacteria. In those cases where the systems appear to be more complex, additional information about molecular mechanisms and physiological functions will be necessary before definitive comparisons can be made.

### Seismic precursors before rock failures in mines

B. T. Brady

United States Department of Interior, Bureau of Mines, Denver Mining Research Center, Denver, Colorado\*

Seismic precursors (such as anomalous V<sub>p</sub> values and/or seismic activity) whose behaviour is qualitatively similar to those reported to precede earthquakes are observed before rock failures in dry underground mines. Similar processes may be involved during failure of rock in the mine and the earthquake, and diffusion of fluids into the focal region of a potential earthquake may not be a necessary condition to produce most of the precursors reported.

EVIDENCE is presented here that seismic precursor effects, such as anomalous  $V_p$  values and/or seismic activity, are observed before rock failures in underground mines. Seismic precursor information for rock bursts in a deep (5,000 feet) silver mine in northern Idaho and a roof fall in a Pennsylvania coal mine is discussed. These mines are dry and the effects of fluids on the seismic precursors are precluded.

\* Present address.

### Rock bursts at Galena

The Galena mine is located in the Coeur d'Alene mining district in northern Idaho. Silver, lead and zinc are the predominant metals mined from steeply dipping veins in the Belt formation series of Precambrian quartzites and argillites. A horizontal cutand-fill mining system is used, with the mill tailings being pumped back into the mine to become the floor for the succeeding cut as mining proceeds from a lower level to a level 300 feet above. Detailed information relating to this type of mining system is available elsewhere1.

Rock bursts in the Galena have occurred in dry pillars at depths of 2,000 to 4,900 feet. In this article, rock bursts are qualitatively identified as small bursts (no damage to adjacent mine structures), bursts (no major damage to adjacent mine structures) and major bursts (substantial damage incurred to the adjacent mine structures). Past experience at the Galena has shown that the number of damaging rock bursts increases dramatically once the pillar thickness has been reduced to

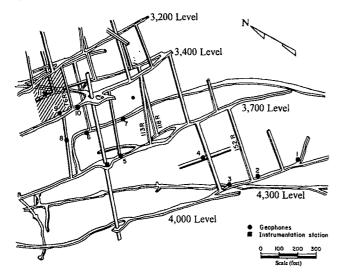

Fig. 1 Geophone locations and mine layout at the Galena mine<sup>2</sup>.

approximately 50 feet. Computer simulation of this mining method has also shown that the maximum principal stress reaches its peak value once the pillar thickness is reduced to 50 feet (ref. 2).

During 1968, detailed microseismic monitoring of potential rock burst zones at the Galena was begun by the United States Bureau of Mines<sup>2</sup>. To monitor a large part of the mine, geophones were placed on three different levels (3,400, 3,700 and 4,000 feet). Figure 1 shows the geophone locations (1-11) and the location of the monitoring station. Some of the results from one active zone (76R) are shown in Figs 2, 3 and 4. In Fig. 2, seismic activity, or equivalently rock noise count against time and pillar thickness, is indicated. The rock noise counts represent small rock failures in the immediate vicinity of the pillar. Note that typically little or no seismic activity is observed during the sandfill operation since the state of stress in the vicinity of the pillar is not changing. Cumulative plots of rock noise source locations are shown in Fig. 3. Seismic P-wave velocity  $(V_p)$ variation with time is shown in Fig. 4. Seismic velocities were obtained for each day on which a blast occurred in 76R. These velocities allowed precise (±20 feet) location of rock noises. Accuracy of seismic velocities is estimated to be  $\pm 100$  feet s<sup>-1</sup> (ref. 2). The P-wave variation with time in Fig. 4 for geophone stations 4, 5, 6 and 7 represent typical variations for all geophone locations.

Examination of Figs 2, 3 and 4 lead to the following observations. (1) The P-wave velocity increased to an apparently stable value for each geophone location once the pillar thickness was reduced to 48 feet. This result agrees with the observation that the maximum principal stress approaches a peak value once the pillar thickness is reduced to 50 feet (ref. 2). The P-wave velocity should also approach its maximum value at this time since

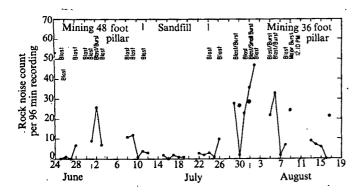

Fig. 2 Rock noise count plotted against time. (After ref. 2).

seismic velocities are known to be positively correlated with the maximum principal stress. (2) Before the major burst on August 9, the noise count in and adjacent to the pillar decreased distinctly. Noise counts resulting from the bursts of August 5 and 6 include noise counts from both zones. But when the source of each rock noise was located and separated into counts for each zone, the noise counts for the separate zones were found to decrease to low values before each of the bursts. The decrease

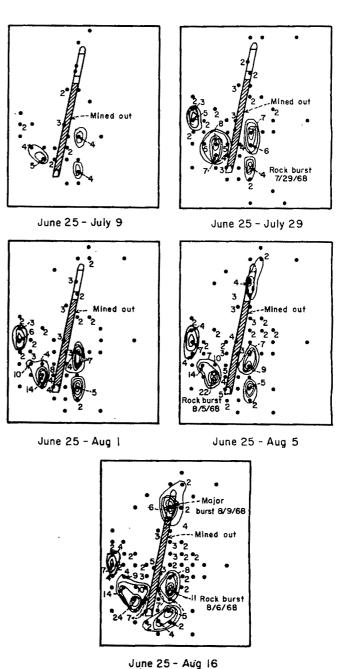

Fig. 3 Cumulative plots of rock noise source locations, 1968. (After ref. 2).

in each zone, however, was not as distinct as that observed for the major burst on August 9. No apparent decrease in noise count was observed before the small burst on August 1. These results suggest that the volume of rock involved in the burst may be an important factor in determining whether precursor phenomena, such as anomalous seismic activity, are observed before rock failures. (3)  $V_p$  decreases by approximately 6-8% before the rock bursts on August 1, 5, 6 and 9 shown in Figs 2,

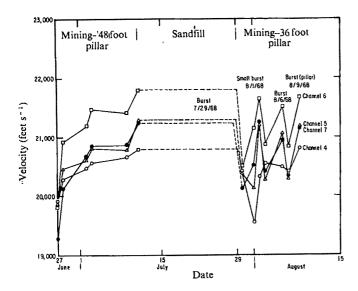

Fig. 4 P-wave variation with time and pillar geometry (76R).

3 and 4, and in general then regains its normal value, although the burst on August 6 did not occur when the velocity had returned to normal. This apparent exception may be a result of the effects produced by the burst of July 29 which occurred directly below the August 6 burst (Fig. 3). Note also that with the exception of the major burst on August 9, the other bursts occurred immediately after blasting.

The time intervals between the blasts in 76R are too long to attach much significance to most of the rock burst data in Fig, 4. It is significant, however, that the bursts of August 1 and 5 did occur when  $V_p$  had reached its normal value. The fact that these bursts occurred shortly after blasting precluded accurate determination of the time interval (precursor time) required for  $V_p$  to regain its normal value. This was not the case for the burst on August 9, which evolved independently of the possible effects produced by rapid load transferral as a result of blasting, which are reflected by the premature bursts on July 29, August 1, 5 and 6. It is important to note that before August 7, the noise count data suggest that there was a pronounced increase in stress within the pillar (Fig. 3). On August 8, however, there were few rock noises in the pillar even after blasting. The decrease in noise count in the pillar occurred at the same time that the P-wave velocity was increasing. This observation suggests that rather than releasing strain energy in the form of rock noises, the pillar had instead 'tightened up' and was storing strain energy. This effect could explain the observed increase in  $V_p$  and the decrease in the noise count before the burst. There are no data available on possible seismic activity that may have occurred in the pillar a few hours before the burst.

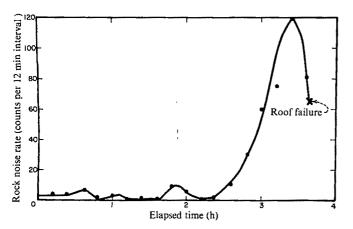

Fig. 5 Roof rock noise rate against time before roof failure.

### Coal mine roof fall

A recent application of microseismics is to provide an early warning of roof falls. The system used by the Bureau of Mines<sup>3</sup> had its first test during a controlled roof fall experiment conducted at the experimental coal mine of the United States Bureau of Mines at Bruceton, Pennsylvania. A room was first mined out and then widened in 0.31-m increments until the roof failed. The rate of emission of rock noise was monitored during mining. The results, illustrated in Fig. 5, show an anomalously high rate of rock noise emission beginning approximately 1 h before the failure. The noise count reached a maximum which

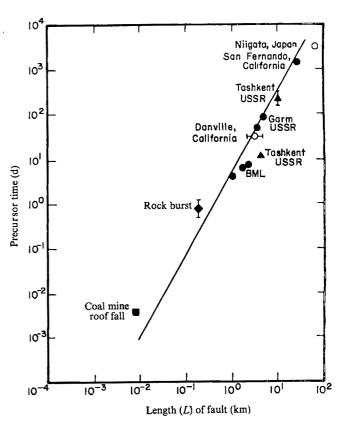

Fig. 6 Precursor time for several different failures as a function of source dimension.  $\bigcirc$ , Crystal movements;  $\blacktriangle$ , radon emission;  $\bullet$ ,  $V_p/V_a$  anomaly;  $\blacklozenge$ ,  $V_p$  anomaly;  $\blacksquare$ , noise count.

was then followed by a distinct decrease preceding the failure by about 10 to 15 min. The area of roof rock involved in the failure was approximately 70 m<sup>2</sup>.

### **Implications**

Observations at Garm (Soviet Union), the New York Adirondacks and for the San Fernando, California earthquake have shown that before these earthquakes the ratio of longitudinal  $(V_p)$  and shear  $(V_s)$  seismic velocities,  $V_p/V_s$ , decreased to anomalously low values and that earthquakes occur shortly following the return of  $V_p/V_s$  to its normal value<sup>4-7</sup>. These studies have also shown that  $V_p$  behaviour is the primary factor in the anomalous  $V_p/V_s$  behaviour. Anomalous behaviour in seismic rate (beginning before earthquakes) whose trend is qualitatively similar to that discussed earlier in mine failures has also been reported by Scholz et al. who reported that seismic activity decreased as the  $V_p/V_s$  value decreased before an earthquake of M = 2.5 in the Blue Mountain Lake region. They also observed that the seismic activity did not increase as  $V_p/V_s$ subsequently increased but decreased further; just before the earthquake the activity increased. Some investigators have explained the behaviour of these precursor effects by requiring

the diffusion of fluids into the dilatant region of an impending earthquake4,6,7.

Precursor time  $(\Delta \tau)$  versus 'effective length' (L) of the fracture area for the August 9 burst and the coal mine roof fall are listed in Fig. 6. The precursor time for the rock burst was between 1 and 2 d. The effective length for the rock burst is approximately 100 m. This estimate is based on rock source locations following the burst. The effective length for the roof fall is approximately 8 m. (Both data points lie quite close to the general trend of  $\Delta \tau$ against L observed to hold for earthquakes.) The magnitude of the rock burst of August 9 was calculated to be M = 2.5 based on data obtained from seismographs located in the mining district. The precursor time against magnitude relationship for this rock burst can be shown to follow the same relationship as that observed to hold for earthquakes<sup>6,7</sup>.

These data have two important implications. First, similar processes may be involved during failure of rock both in the mine and in the earthquake region; that is, rock failure is scale independent. Second, diffusion of fluids into the focal region of a potential earthquake may not be necessary to produce most of the precursor effects reported to occur before an earthquake since qualitatively similar precursor effects are observed in mines where no fluids are present.

I have developed a scale-independent failure theory governing the initiation and growth of shear faulting in dry rock that provides an explanation of why the precursor time-lengthmagnitude relationships hold for mine failures and earthquakes. A detailed account and implications of this theory will be published elsewhere8.9.

### Observations of the radio galaxy DA240 at 11 cm

THE radio source DA240 (refs 1 and 2) has been identified<sup>3</sup> as a 15-mag elliptical galaxy of redshift z=0.0356, placing it at a distance of 215 Mpc (assuming an Einstein-de Sitter cosmology with  $c/H_0=6,000$  Mpc). The total angular extent of the source is approximately 34', which implies a linear extent of 2.1 Mpc and makes it one of the largest systems known.

As part of a programme of source polarisation observations undertaken with the Effelsberg 100-m telescope, we have mapped the polarisation and total density distribution across DA240 at a wavelength of 11 cm with a resolution of 4.8' (Fig. 1). The mode of observation and reduction has already been described'. The map was constructed from sets of right ascension scans. They did not, however, extend far enough to the west, so the base level of each scan was determined from the eastern extremity only and no gradient of base-level along the scan was removed. The map was not made under ideal atmospheric conditions, so that the limitation to the accuracy of the unswitched total intensity output is the accuracy of base-level determination. For example, a combination of several scans with a sloping base level is evident 4' north of the map's centre at the 30 mJy level. The switched polarisation output is, in contrast, virtually unaffected by the weather, being only limited by noise at the 5 mJy level. We will discuss the three components of the source DA240 individually.

North-east component. At our resolution, the extended area is overshadowed by the strong compact component 4C56.16. The distribution of polarised flux is closely similar to the distribution of total flux over the central area of this component with a percentage polarisation close to 11% at a position angle of 63°. But on the southern edge the vectors swing around to position angles near 150° and the percentage polarisation rises to over 20%.

The percentage polarisation at 49 cm, both for the compact north-east component and the adjacent low brightness area, is 22% (ref. 3), which implies that there is little depolarisation through the source at this wavelength by differential Faraday rotation. The thermal electron density must, therefore, be very low. The differential rotation at 11 cm is 20 times less than at 49 cm but, nevertheless, the polarisation of the compact source and adjacent areas summed within our beam is only 11%. This is unlikely to be caused by differential Faraday rotation across the larger beam, either at the source, as the thermal electron densities there are so low, or in the Galaxy, as the cell size would need to be very small. Rather it must be caused by changes in the intrinsic position angle polarisation. Therefore, the magnetic field direction within the source changes significantly over distances of 1 to 2'.

Central component. At both 11 cm and 49 cm, the peak flux of the central compact component is a factor of 6 weaker than the peak flux of the north-east component. Over this wavelength range the two sources, therefore, have a similar spectrum (spectral index about -0.3), flatter than the spectrum of the more extended components. But the difference in resolution of the two maps makes accurate comparison difficult. The compact sources have, however, quite different polarisation properties, for at 11 cm the polarised intensity associated with the central source is lost in the noise, indicating a percentage polarisation of less than 4%.

South-west component. Unlike the north-east component, the extended area in the south-west is not so dominated by a compact source, and fine scale structure in the polarised radiation is more clearly visible. Although the polarised flux is smaller than in the north-east, the percentage polarisation is higher: around 20 to 30%. Along the source axis, the position angle of polarisation swings from 110° near the centre to 145° about 6' further out. Because this swing occurs over a distance of a little over one beamwidth,

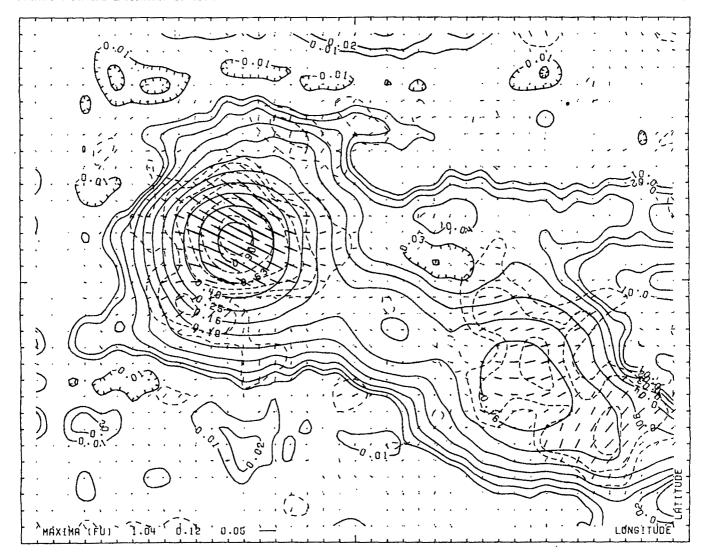

Fig. 1 DA240 at a wavelength of 11 cm. The map is centred on the position given by Bridle et al.<sup>2</sup>:  $\alpha(1950.0) = 07$  h 44 min 55 s,  $\delta(1950.0) = 55^{\circ}$  58' 43" and covers an area of 40' in  $\alpha(286$  s time at this declination) by 30' in  $\delta$ . The markers around the edge are at intervals of 1'. The full contours represent the total intensity; eleven contours labelled to an accuracy of two decimal places, are plotted with a uniform logarithmic decrement of 2 dB from (1.00 down to 0.01) times the (north-east) peak intensity places, are plotted with a uniform logarithmic decrement of 2 dB from (1.00 down to 0.01) times the (north-east) peak intensity of 1,040 mJy, except that the top contour is depressed to the 0.90 level. The dotted contours represent the linearly polarised intensity. Six unlabelled contours are plotted from (1.00 down to 0.10) times the (north-east) linearly polarised peak intensity of 120 mJy, again with the top contour depressed to the 0.90 level. The vectors have a length proportional to the polarised intensity and are oriented along the electric vector of the polarised radiation. The maxima of the total intensity and polarised intensity distributions, together with the length of the unit polarisation vector, are indicated in the lower left hand corner. Longitude and latitude correspond in this plot to  $\alpha/\delta$  (1950.0).

vectors of different orientation are present simultaneously within our beam. This will not influence the position angle of polarisation, but does yield the apparent reduction in polarised flux evident on Fig. 1 between the two areas of maximum. If the magnetic field direction in the source did not change along the axis, this swing in the 11-cm position angles would require a change in rotation measure of 50 rad m<sup>-2</sup>. Rotation measures of this order would yield high depolarisation at 49 cm, in conflict with the Westerbork observations. The rotation of the position angle of polarisation at 11 cm thus reflects a swing in magnetic field direction of  $\sim 35^{\circ}$  along the source axis over a distance of ~ 6'. Significant changes in magnetic field direction therefore seem to occur on a larger angular scale in the south-west component than in the north-east component.

Polarisation and total intensity measurements are planned at shorter wavelengths in order to delineate more precisely the changes of spectral index, rotation measure and particularly magnetic field direction across the whole of DA240.

We thank A. G. Willis and H. van der Laan for providing data in advance of publication. During these observations J.B.W. was on leave of absence from Radiophysics Laboratory, Commonwealth Scientific and Industrial Research Organisation, Epping, NSW, Australia.

### A simple model of a Friedmann universe filled with a quantised scalar field

It is widely felt that the ultimate resolution of the problem of gravitational collapse awaits the formulation of a good theory of quantum gravity. Recently, however, it has been suggested (L. Parker and S. A. Fulling, unpublished) that singularities may be avoided because of quantum effects of the matter distribution rather than those of the gravitational field. When the radius of curvature of space-time becomes of the order of, say,  $10^{-13}$  cm one expects that the matter distribution might be more appropriately described by a quantum field than by its traditional description as a classical fluid. Since a quantum field need not necessarily respect the energy conditions required by the Hawking-Penrose singularity theorems, there exists, at least in principle, the possibility that in a gravitational collapse the radius of curvature of spacetime may always remain much greater than the Planck length (10-33 cm) at which quantum gravitational effects are expected to become important.

Here I present a simple model related to the occurrence of singularities in a Friedmann cosmology. The model has the virtue that analytic solutions can be obtained which should provide qualitative insight into the results that may be available from a more complete theory.

The model is a 'mini-phase space' calculation in which a massive scalar field is quantised in the background geometry of a Friedmann universe. Coordinates may be chosen so that the line element in a Friedmann space assumes the form:

$$ds^2 = dt^2 - R^2(t) \gamma_{ij} dx^i dx^j \tag{1}$$

where  $\gamma_{ij}$  is the metric of a three-space of constant curvature. The equation of motion of a scalar field in these coordinates may be found from the Lagrangian density

$$\mathscr{L} = \frac{1}{2}g^{1/2}(g^{\alpha\beta}\varphi_{,\alpha}\varphi_{,\beta} - m^2\varphi^2) \tag{2}$$

or equivalently from the action functional

$$\mathcal{S} = \int d^4x [\pi \dot{\phi} - \frac{1}{2}g^{-1/2}\pi^2 + \frac{1}{2}g^{1/2}(g^{ij}\phi,_i\phi,_j - m^2\phi^2)] \qquad (3)$$

in which  $\phi$  and  $\pi$  are to be varied independently. The energy-momentum tensor for such a field is

$$T_{\mu\nu} = 2g^{-1/2}\partial \mathcal{L}/\partial g^{\mu\nu} = \phi_{,\mu}\phi_{,\nu} - \frac{1}{2}g_{\mu\nu}(g^{\alpha\beta}\phi_{,\alpha}\phi_{,\beta} - m^2\phi^2)$$
 (4)

The problem may be simplified by restricting the phase space of the scalar field. I shall require that  $\varphi(x^t, t)$  be a function of the time t alone q(t) say.  $\pi(x^t, t)$  the momentum conjugate to  $\varphi(x^t, t)$  is a scalar density so I require it to be of the form

$$\pi(x^{i}, t) = \gamma^{1/2}(x^{i}) p(t)$$
 (5)

Equation (3) now becomes:

$$\mathcal{S} = \int d^3x \gamma^{1/2}(x^i) \int dt \{ pq - \frac{1}{2}R^{-3}p^2 - \frac{1}{2}m^2R^3q^2 \}$$

For the case in which the space is positively curved  $\int d^3x \gamma^{1/2}$  is a trivial multiplicative constant which we may drop and henceforward take:

$$\mathscr{S} = \int dt \{ pq - \frac{1}{2}R^{-3}p^2 - \frac{1}{2}m^2R^3q^2 \}$$
 (6)

In the cases of zero or negative curvature  $\int d^3x \gamma^{1/2}$  is infinite

though we may make it finite by restricting the range of the spatial coordinates and we shall adopt equation (5) in these cases also. From equation (6) we see that

$$p = R^3 \dot{q} \tag{7}$$

If we now restrict  $T_{\mu}{}^{\nu}$  to this mini-phase space, its non-zero components become

$$\rho \equiv T_0^0 = \frac{1}{2} (R^{-6} p^2 + m^2 q^2) \tag{8}$$

$$P \equiv -T_k^{\ k} = \frac{1}{2}(R^{-6}p^2 - m^2q^2) \tag{9}$$

'Canonical' commutation relationships may be imposed, namely

$$[p,q]=-i$$

The Hamiltonian is tentatively identified from equation (6) as

$$\mathcal{H} = \frac{1}{2}R^{-3}p^2 + \frac{1}{2}m^2R^3q^2$$

Defining a by

$$a = [1/\sqrt{(2m)}] [R^{-3/2}p - imR^{3/2}q]$$

we see that

$$\mathcal{H} = (m/2)(a\dagger a + aa\dagger) = m(a\dagger a + \frac{1}{2}) \tag{10}$$

We must now decide on the ordering of operators to be used in subsequent equations. This is necessary in order to determine correctly the source of the gravitational field. A natural way to do this is to order the operators so that the Hamiltonian becomes

$$\mathcal{H}_{new} = ma^{\dagger}a = \frac{1}{2} \{ R^{-3}p^2 + m^2R^3q^2 - m \}$$
 (11)

This ensures that the lowest eigenvalue of  $\mathcal{H}_{new}$  is zero, this ordering also ensures the correct ordering of the Hamiltonian in the Minkowskian regime when R/R is small.

The Schrödinger equation for the system is:

$$i\frac{\partial}{\partial t}\psi(q,t) = \mathcal{H}\psi(q,t) = \left\{ -\frac{R^3}{2}\frac{\partial^2}{\partial q^2} + \frac{m}{2}R^3q^2 - \frac{m}{2} \right\} \psi(q,t) \quad (12)$$

where the radius function R(t) may be determined from the Einstein equations

$$G_{\mu\nu} = \langle T_{new \, \mu\nu} \rangle \tag{13}$$

once the normal ordered forms of  $\rho$  and P are known. Direct calculation from equations (8) and (9) yields

$$d(\langle \rho \rangle R^3)/dt + \langle P \rangle dR^3/dt = 0$$
 (14)

But it follows from (13), by the contracted Bianchi identities that

$$d(\langle \rho_{new} \rangle R^3)/dt + \langle P_{new} \rangle dR^3/dt = 0$$
 (15)

 $\rho_{new}$  is determined from equation (11) by

$$\rho_{new} = R^{-3} \mathcal{H}_{new} = \rho - mR^{-3}/2 \tag{16}$$

Subtracting equation (15) from equation (14) then yields

$$P_{new} = P \tag{17}$$

The complete system of equations is now (henceforward all quantities are understood to be normal ordered)

$$i\partial \psi/\partial t = \frac{1}{2}(R^{-3}p^2 + m^2R^3q^2 - m)\psi$$

$$G_{\mu}{}^{\nu} = \langle T_{\mu}{}^{0} \rangle \cdot$$

$$\rho = \frac{1}{2}(R^{-6}p^2 + m^2q^2 - mR^{-3})$$

$$P = \frac{1}{2}(R^{-6}p^2 - m^2q^2)$$
(18)

We observe that although the energy density is a positive definite operator the pressure is not. Indeed the quantities  $\langle p \rangle + \langle P \rangle$  and  $\langle p \rangle + 3 \langle P \rangle$  may be negative so that the 'strong energy condition' may be violated. This violation of the energy inequalities is not directly a consequence of the normal ordering prescription, since the strong energy condition is not satisfied even by a classical massive scalar field.

The exceptional case m=0 is trivially analysed, for then  $\langle \rho \rangle = \langle P \rangle \geqslant 0$ , the conditions of the singularity theorems are satisfied and a singularity ensues.

For m > 0 it will be convenient to consider the cases k = -1, 0, +1 separately. The Einstein equations may be written in the form

$$6\ddot{R} = -(\langle \rho \rangle + 3\langle P \rangle)R$$

$$\dot{R}^2 + k = \frac{1}{3}\langle \rho \rangle R^2$$
(19)

When k=-1,  $R(t) \ge 1$  so that R(t) can have no minimum, hence R=0 at some finite time.

When k = 0,  $R(t) \ge 0$ ; if  $\dot{R}(t_0) = 0$ ,  $R(t_0) > 0$  for some  $t_0$  then

$$\langle \rho \rangle |_{t_0} = \langle P \rangle |_{t_0} = 0$$

We make the assumption that solutions of equation (18) subject to appropriate initial data are unique. Then we must have a constant solution  $R(t) = R(t_0)$ , that is, we have Minkowski space-time. The same considerations obtain also when  $t_0 = -\infty$ .

When k = +1, there exist solutions which collapse to a singularity or bounce (as we go backwards in time) depending on the initial data.

To show that a singular solution exists we may construct a self-consistent asymptotic solution to the equations (18). Near R=0 we have

$$\psi_k(q,t) \sim \exp\left\{-\frac{ik^2}{2}\int^t \frac{\mathrm{d}s}{R^3(s)} + ikq\right\}$$

with this wave function

$$\langle \rho \rangle \sim \frac{1}{2} k^2 R^{-6}, \quad \langle P \rangle \sim \frac{1}{2} k^2 R^{-6}$$

and hence by equation (19)

$$R(t) \sim [\sqrt{(3/2)kt}]^{1/3}$$

which has a zero at t = 0.

To construct a solution which has a local minimum in R(t) at t = 0 we choose as an initial state

$$|t=0\rangle = (1+\lambda^2)^{-1/2}(|0\rangle + \lambda|2\rangle)$$

where  $|0\rangle$  and  $|2\rangle$  are the eigenstates of  $\mathcal{H}(t=0)$  with eigenvalues 0 and 2m respectively. At t=0 we have

$$\langle \rho \rangle = \lambda^2 2m R^{-3}/(1+\lambda^2)$$
  $\langle P \rangle = \sqrt{2\lambda} 2m R^{-3}/(1+\lambda^2)$ 

If  $0 > \lambda > -3\sqrt{2}$  then  $\langle \rho \rangle + 3\langle P \rangle < 0$ . Choosing

$$R(0) = 2\lambda^2 m/[3(1+\lambda^2)]$$

we have  $\dot{R}(0) = 0$  and  $\ddot{R}(0) > 0$  so that R(t) has a local minimum at t = 0

From equation (18) we see that for  $R(t) \ll m^{-1}$  the equations approach, in some sense, those obtaining for zero mass for which collapse is inevitable. For any  $\varepsilon > 0$  a set of solutions of non-zero measure satisfies  $R(t) < \varepsilon m^{-1}$  for some t, and for sufficiently small  $\varepsilon$  a subset of non-zero measure of these will collapse. Thus we see that the set of solutions which exhibits a singularity is of non-zero measure.

The results of this calculation indicate that the introduction of a quantised matter source into the Einstein equations does not cause the system to 'conspire' to evade a singularity. It is of interest to note that the results of this calculation are in accord with the results obtained by L. Parker and S. A. Fulling, and W. F. Blyth and C. J. Isham, unpublished. I acknowledge fruitful conversations with Dr D. J. Raine and thank the Science Research Council for financial support.

### Origin of fifteen cosmic dust particles intercepted by Pioneer 8 and 9

Two identical cosmic dust particle experiments on board the heliocentric space probes Pioneer 8 and 9 have now yielded consistent data for more than 8 yr. The two spacecraft are in direct heliocentric orbits with perihelia between 0.75 AU and 1.00 AU and aphelia between 1.00 AU and 1.10 AU, respectively. Their orbital velocity is approximately 30 km s<sup>-1</sup> and both satellites are spinning at 1 r.p.s. about an axis perpendicular to the ecliptic plane, and carry similar cosmic dust detectors scanning the ecliptic plane<sup>1-4</sup>. The instrumentation, its calibration, and significant scientific results have been reported<sup>1-3</sup>.

We are primarily concerned with the time-of-flight data which provided orbital characteristics of small interplanetary dust particles in the solar system. Out of the total 20 events recorded to date, 5 show hyperbolic characteristics and are excluded from this specific study. The semimajor axes and eccentricities for the remaining 15 elliptic orbits are shown in Table 1.

There are two general criteria one can apply to determine the origin of these dust particles. Whipple has introduced an empirical relationship to distinguish cometary particles from asteroid objects<sup>5</sup>, referring to it as the K criterion defined as

$$K = \log [a(1+e)/(1-e)] - 1$$
 (1)

where a is the semimajor axis in AU and e is the eccentricity. K is positive for the majority of cometary orbits and negative for the majority of asteroids. This K criterion has no basic physical significance, except as a useful tool in any discussion of the general characteristics of the meteor orbits and their origin. Computed values of K for the Pioneer 8 and 9 events are shown in Table 1. According to the K criterion, eight particles are definitely asteroidal and two are cometary. The remaining five events are intermediate and uncertain. Computed Tisserand invariant T also shows that with the exception of event 14, all of them have T greater than 1.00 and thus align with the Apollo group<sup>6</sup>. The 15 elliptical orbits have small semimajor axes, small perihelion distances, and moderate eccentricities,

Listed as numbered by Berg et al.2.

Due to uncertainties in the calibration curve (typically velocities:  $\pm 18\%$ , inclinations:  $\pm 27^{\circ}$ ), three sets of possible orbital parameters are shown for each event and represented as a, b, and c. The particle mass density has been assumed to be 3 g cm<sup>-3</sup> in this analysis.

typical of the Apollo group asteroids. They cannot be the remnants of typical comets but must presumably have been produced at closer distances to the Sun.

We conclude that the majority of dust particles having elliptical orbits detected by Pioneer 8 and 9 space probes show orbital characteristics of Apollo group asteroids which originated from residual nuclei of short-period comets7.

### Generation of magma at lunar impact crater sites

Many lunar craters have lava flows associated with them. It is widely accepted that, in most cases, the craters are the result of meteoric impact and not volcanic activity but, if so, the occurrence of lavas needs explaining. It is commonly supposed that the lava flows are material that was melted during the impact process itself but this is not acceptable as a general explanation, for two reasons. First, in several cases the ages of the lavas have been found, by crater counting techniques, to be significantly younger than the craters themselves1 and so they cannot have been formed at the time of impact. Second, some of the lavas show morphology typical of terrestrial lava flows and it is possible to deduce from this that the lava came from sources similar to those of terrestrial volcanoes—that is, lava was supplied at a fairly steady rate over periods of several days and was not simply splash-out from a meteoric impact<sup>2</sup>. It therefore seems that these lava flows are a product of the presence of an impact crater and yet have occurred as normal volcanic effusions long after the formation of the craters.

Terrestrial volcanism is strongly correlated with lithospheric plate margins. This implies that some process occurs at these margins to generate magma since there is no earthwide magma reservoir. Many mechanisms have been postulated but a likely one is that of frictional or dissipative heating due to relative motion of the plates. Shaw<sup>3</sup> showed that typical lithospheric shear stresses in systems greater than 10 km in extent would probably cause melting in the mantle, as a result of viscous dissipation, in a time of about a million years. Presumably a similar process could operate on the Moon to generate magma.

There is little evidence that there has ever been widespread motion of lithospheric plates on the Moon and it seems unlikely that this could have been the way in which magma was generated. Large scale convective motions within the Moon have been postulated but these are unlikely to penetrate nearer than 300 km to the surface4.5. Any magma generated in these motions would not be linked to the formation of impact craters except possibly the largest ones.

There is a further source of motion within the lithosphere which is associated with the formation of impact craters. It is well known that craters become shallower with age and this may be explained by a process of recovery due to viscous creep within the lithosphere. The removal of material from the surface which occurs at the formation of an impact crater produces non-hydrostatic stresses within the lithosphere which are large enough to produce a slow viscous flow. Gash<sup>6</sup> has presented a rheological model of the lithosphere which accounts for the rates of recovery of lunar craters. The model involves

Table	Recovery and melting data

viscous flow at stresses greater than a yield value and much slower, though still viscous, flow at weaker stresses. The result is that craters recover relatively rapidly to a depth of about 3 km on the Moon but at a much slower rate when they are less deep. It seems possible that enough heat will be generated during the period of rapid recovery to produce magma beneath a crater. This would explain not only the production of lava at crater sites but also the time interval between the formation of a crater and the lava. Pike<sup>7</sup> discussed several ways in which lava might be generated beneath craters but found no satisfactory explanation; he preferred a process dependent on the recovery of craters to a state of isostasy. The process described here is of this kind.

Preliminary calculations have been made to assess the viability of recovery-induced melting. Gruntfest<sup>8</sup> analysed the phenomenon of dissipative heating in the presence of a temperature dependent viscosity and Shaw2 applied the results to geophysical situations. Gruntfest<sup>8</sup> showed that the effects of dissipation could be described by a parameter G which is the ratio of the rate of production of heat due to dissipation to the rate of loss of heat due to thermal conduction. For values of G less than a critical value of 0.88 in a plane shear situation the effect of dissipation is to raise the temperature slightly. After a characteristic thermal relaxation time the temperature remains steady. For values of G greater than the critical value a steady state is not achieved; eventually the temperature rises rapidly. For  $G \gtrsim 10$  the system is effectively adiabatic and the temperature theoretically becomes infinite in a finite time. In practice the increasing temperature brings about a change of phase with the result that heat is lost more rapidly, thus braking the process.

G was defined as

$$(\beta \tau^2 l^2)/\lambda \eta_0$$

where  $\tau$  is the shear stress,  $\beta$  the temperature coefficient of viscosity,  $\eta_0$  the viscosity at the initial temperature  $T_0$ ,  $\lambda$  the thermal conductivity and I the path length for thermal conduction. In the case of the recovery of lunar craters this definition needs to be modified to allow for the non-Newtonian properties of the flow. The rate of dissipation is equal to the stress multiplied by the velocity gradient,  $\nu$ . For the lunar lithosphere it is assumed, following Gash, that

$$\tau - \tau_y = \eta v$$

where  $\tau_y$  is the yield stress and  $\eta$  the viscosity so that the rate of dissipation equals

$$\tau(\tau-\tau_y)/\eta$$

This falls to zero as the stress reduces to the yield value—that is when the rapid recovery phase ends. G may be redefined, for this situation, as

$$G = \beta \tau (\tau - \tau_v) l^2 / \lambda \eta_0$$

The stress distribution beneath craters is not well known. Jeffreys<sup>9</sup> concluded that a stress of from one-half to two-thirds the surface load would exist initially beneath an excess load. For the case of a surface indentation it seems that some concentration of stress will occur<sup>6</sup> and so it is a reasonable approximation that the maximum non-hydrostatic stress beneath a crater will be equal to the maximum surface load which is  $(g\rho d)$  where d is depth of the crater and  $\rho$  the density of the lithosphere. The depth changes in time, due to the recovery process, and the change may be expressed by

$$d = d_0^{-\alpha t} \exp(-\alpha T)$$
  

$$\alpha = g \rho D_0 / 4\pi F \eta$$

 $D_0$  is the initial diameter of the crater, and F is an empirical factor introduced by Gash<sup>6</sup>. The situation is further complicated by the fact that the rate of recovery—and hence the rate at which the stress changes—is viscosity dependent.

Apart from the steady decrease in stress there are other difficulties in evaluating G for the case of lunar craters. As the temperature rises the rheology of the lithosphere will change: the yield stress will decrease and the temperature coefficient of viscosity is unlikely to remain constant. Gruntfest assumed a variation of the type

$$\eta = \eta_0 \exp(-\beta (T - T_0))$$

For a solid, the creep viscosity is more likely to follow<sup>4</sup>

$$\eta = \eta_0 T e^{E/kT},$$

where E is the activation energy for viscosity and k is Boltzmann's constant. This means that

$$\beta \sim -E/kT^2$$

and therefore varies with temperature. Tozer<sup>4</sup> predicts that E/k for the lunar lithosphere will be about 25,000 K so that  $\beta$  will range from about 0.02 just below the melting point to almost 0.3 at 300 K. Finally, the value of I is not well defined. For a crater, the depth at which maximum stress occurs is probably near to 25% of the crater diameter<sup>9</sup>. Therefore, the conduction path to the surface is probably the dominant one and I should be put equal to  $D_0/4$  although the region in which heating occurs may have a horizontal extent which is greater than this.

It follows that, for a crater,

$$G = \beta \tau (\tau - \tau_y) D_0^2 / 16 \lambda \eta_0$$

Following Gash<sup>6</sup> it is assumed that  $\eta_0 = 4 \times 10^{21} \ \text{Pa} \ \text{s}$  and  $\tau_{\nu} = 1.7 \times 10^7 \text{ N m}^{-2}$ . Before any rise in temperature  $\beta$  will be about 0.25  $K^{-1}$  and  $\lambda$  will be approximately 2 W mK<sup>-1</sup>. With these values G will be equal to its critical value at the start of the recovery process for a crater about 35 km in diameter. This is about twice the diameter of the smallest craters subject to rapid recovery<sup>6,7</sup>. This suggests that the recovery of a crater of this size may eventually produce high temperatures. It seems that the recovery of craters which are not much larger would almost certainly give rise to melting but it must be remembered that as the temperature rises both the stress and the rate of change of viscosity with the temperature decrease and so tend to reduce the rate of temperature rise. The heating will cease when the rapid recovery phase is completed and so a further requirement for melting to be achieved is that high temperatures must be produced before rapid recovery is complete.

If it is assumed that G is large enough for the process to be adiabatic then the time,  $t_{\rm ad}$ , taken for the temperature to become very large is

$$t_{ad} = \rho c \eta_0 / [\beta \tau (\tau - \tau_y)]$$

where c is the specific heat of the lunar material. The ratio M of recovery time to the time required to achieve melting reduces to

$$M = (4\pi F g \beta/c)(d_0/D_0)^2 (D_0 - D_s) \ln(D_0/D_s)$$

where  $D_s$  is the diameter of the smallest crater subject to rapid recovery and is somewhat less than 20 km on the Moon. The ratio M must be large if melting is to occur. For a 35-km diameter crater M is about 7 and so high temperatures will be produced long before recovery is complete. Some examples of characteristic recovery times for the rapid recovery phase and times needed to achieve melting are given in Table 1.

It is likely that these melting times are underestimates because of the tendency for the rate of heating to decrease as the

where

temperature rises and as recovery proceeds. It seems clear from these preliminary calculations that viscous dissipative heating could have been of major importance in the recovery of larger lunar craters. More elaborate computerised calculations may help to reveal more details of the process when more of the complexities of the situation are accounted for.

The arguments given here suggest that, for lunar craters larger than a certain size—not much greater than the minimum size of craters which undergo rapid recovery—the process of recovery gives rise to a great increase in temperature in a region beneath the crater and probably causes melting. It is hard to estimate how much melting might occur because the extent of the heated region is not known. The calculations of Gruntfest<sup>8</sup> showed that the temperature of a sheared slab does not increase equally at all points. Although the material is initially homogeneous its response to shear stress is heterogeneous and melting first occurs in a very narrow region. Furthermore, experimental work with liquids which show a marked change in viscosity at some yield stress has shown that the regions in which the lower viscosity is displayed are very narrow when the stress is of the order of the yield stress2. These regions appear as shear planes along which the strain rate is high. This evidence suggests that melting will occur in narrow zones along shear planes in the lunar lithosphere. The temperature will continue to rise and the amount of melting will increase until the system is disrupted—probably by an effusion of magma to the surface. This process may be repeated periodically. It seems that the initial melting may take up to 10<sup>7</sup> yr for the smaller craters but perhaps as little as 104 yr for the largest craters.

The depth at which melting occurs is likely to be related to crater diameter and is probably of the order of 25% of the diameter. For most craters the melting region will be within the cool lithosphere but beneath the largest craters dissipation of energy will occur in deeper material which is initially much warmer and of more basic composition than the outmost layers of the Moon. Melting will be achieved in shorter times than those given in Table 1 when the material is warmer, because of the reduced viscosity. G will remain supercritical for relatively longer in the larger systems with lower viscosity and so many more episodes of melting may occur before recovery is complete in larger craters. It would be expected that the composition of lavas would be dependent on crater diameter and this is what is generally observed. Lighter, more acidic lavas are associated with smaller craters whose sources are near the surface and dense basaltic lavas from deep in the Moon are found in the largest craters and the maria. For example, the lavas associated with the crater Tycho apparently have higher yield stresses and hence are probably more acidic than those of Mare Imbrium<sup>2</sup>.

### Dependence of seismic mean residuals on distance, azimuth and time

Most studies on the changes of sesimic velocity which precede earthquakes (see, for example, refs 1-5) are based on data from highly sensitive, but local, seismic networks. Large earthquakes very rarely occur in the neighbourhoods of these networks, so to study velocity changes associated with earthquakes of large magnitude, it is better to use a worldwide network of stations such as those reporting to the International Seismological Centre (ISC) in Edinburgh. Studies of this kind, on the teleseismic residuals over an eight-year period at Matsushiro, have been reported by Wyss and Holcomb<sup>6</sup>. Their results show a clear

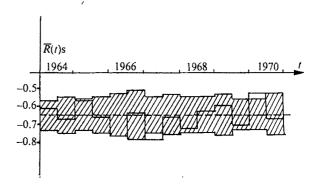

Fig. 1 The continuous line shows the mean residuals for the fourteen half-yearly periods covered by this study. ———, Overall mean residual. Hatched area denotes the 95% confidence limits for each half-yearly period, centred on the overall mean.

jump in the mean P-wave residuals in 1963, 2.5 yr before the beginning of a large earthquake swarm in the vicinity of the seismic station. Since the variation is very close to the level of statistical significance, I have made a study of similar anomalies at other stations close to the epicentres of strong earthquakes. The period covered by the data, which have been taken directly from the ISC Bulletins, is 1964-70.

Each six-month period was taken separately and all residuals under 5 s for first arrivals of P waves were used. These were divided into groups by azimuth (90° sections) and by distance (0-10°, 10°-20°, 20°-40°, 40°-60° and more than 60°), and the mean was calculated for each group (and for each six-month period and for every listed station).

Mean residuals were first calculated for seismological stations in aseismic areas in order to test whether the averaging procedure really cancels the influence of factors like differences in source mechanism, propagation path and so on. (The spatial pattern of earthquakes in different periods of time may, for instance, have a strong effect on the time variation of the mean residuals.)

As an example, the mean residuals for the Uppsala station are shown in Fig. 1. The histogram summarises the results for the 14 half-year periods. The residuals lie within  $\pm 0.14$  s of the overall mean value of -0.65 s, thus showing good stability. In two cases the observations lie outside the confidence limits, so there still remains the possibility of slight non-random variations in the mean residuals, but undoubtedly the averaging procedure is reasonably effective in suppressing irrelevant effects.

The result of -0.65 s for the overall mean residual, with a standard error of 0.01 s, was calculated from 8,553 residuals. The negative value seems to correlate with the known tendency of the Uppsala station to assign high values to the magnitudes of some seismic events. Early arrivals (negative residuals) correspond to high velocities which are normally associated with low attenuation (high Q) and, therefore, large magnitudes. Many other Scandinavian stations have negative mean residuals,

The standard error is included with each evaluation and the number of residuals used is shown.

the magnitudes of which increase towards the centre of the Scandinavian peninsula. In North America, apart from a cluster of stations in central California with positive residuals, stations have mainly negative residuals. This too, seems to correlate with the distribution of magnitude anomalies for North American stations (A. Douglas, personal communication).

Results from many other stations in aseismic areas show the same stability. Some, however, reveal statistically significant changes in time over the period 1964–70. This would be expected in cases where changes of instrument or method of detection of first arrivals have taken place. At some stations there is a strong dependence of residuals on distance and azimuth (see, for example, Table 1).

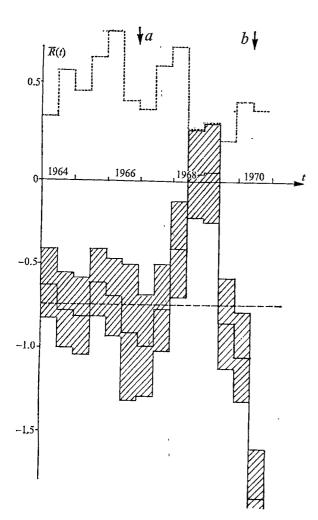

Fig. 2 Mean residulas at station Nana for the fourteen half-yearly periods with the 95% confidence limits denoted by hatching. — —, Mean residuals for station Huancayo. The arrows show the times of onset of the 1966 and 1970 Peruvian earthquakes; a, M = 7.75-8, October 1966,  $\Delta + 2.2^{\circ}$ ; b, M = 7.6, May 1970,  $\Delta, +3.4^{\circ}$ .

I now consider four sets of residuals at stations situated in the vicinity of large earthquakes which occurred in the period 1964—70. The first set is from the Nana and Huancayo stations, which are near the epicentres of the 1966 and 1970 Peruvian earthquakes. Figure 2 shows the variation of the residuals with time.

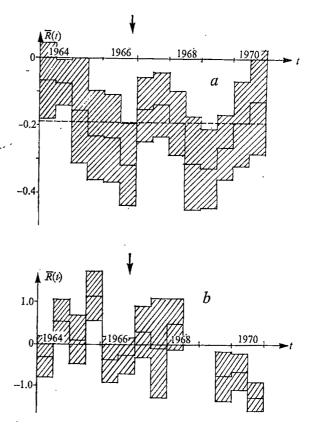

Fig. 3 Mean residuals with 95% confidence limits for Antofagasta (a) and Copiapa (b). The arrows show the time of onset of the December 1966 Chilean earthquake; a, M = 7.75-8; b, M = 7.75-8.

A statistically significant reduction in seismic velocities occurred at Nana two years before the latter event. An analogous reduction, smaller in size and occurring slightly earlier, appears for Huancayo which is a little further from the epicentre (shown without confidence limits as a dotted line in Fig. 2). On the other hand, the first earthquake is preceded by a jump in the residuals at Huancayo station only; variations at Nana before 1968 are statistically insignificant.

A second example is the Chilean earthquake of December 1966. There were two stations close to the epicentre  $(\Delta \sim 2^{\circ})$  but on almost opposite sides, Antofagasta and Copiapa. They show significant changes in mean residuals before the earthquake (see Fig. 3a and b), but they have a rather complicated structure. The pattern of a drop in velocity one or two years before the earthquake is, however, repeated at each station.

Figure 4 shows the time variation of the residuals at the Przevalsk station, 0.23° from the epicentre of a magnitude 6.8 earthquake in 1970. They follow the pattern of the Nana residuals very closely. Unfortunately, reports from the station to the ISC ceased for a 1.5-yr-period preceding the event. Significant changes in level were reported by Bullanzhe, Atrushkevich<sup>7</sup> and others in Alma Ata city, which is close to Talgar, following the earthquake.

The final example (Fig. 5) is taken from data at the Makhachkala station, situated 0.24° from the epicentre of a strong Dagestan earthquake in 1970. Because of the small number of events reported by this station, the statistics are rather poor. The pattern of variations of the mean is, however, quite similar to those of the preceding examples.

In conclusion, mean residuals of P-wave arrivals (R) show statistically significant time variations at seismic stations which are close to future earthquakes. The variations have a rather

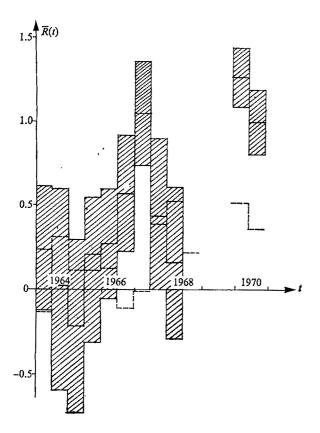

Fig. 4 Mean residuals with 95% confidence limits for Przevalsk. ———, Mean residuals for Talgar, a station situated five times further away. The arrow shows the time of onset of the June 1970 earthquake; M = 6.8.

complicated structure but the main general feature is a jump in value before the earthquake. This corresponds to a decrease in velocity and is in agreement with the predictions of the dilatancy hypothesis. The distance at which variations of R could be detected is a few times larger than the sizes of the source as determined by the aftershocks zone and by level measurements. R depends strongly on the distance and azimuth of the source. It is correlated with magnitude anomalies in a way which confirms the physical interpretation: lower attenuation corresponds to higher seismic velocities.

I thank Professor V. I. Keilis-Borok for suggesting this study and Dr E. P. Arnold for advice and encouragement. Assistance was received from Mr D. MacGregor of the ISC, Mr G. McNair,

### Seismic slip rates in the Mediterranean and Middle East

Various plate tectonic models have been suggested for the Mediterranean and Middle East<sup>1-3</sup>. These differ in detail, but all require several smaller plates to account for the complicated seismicity observed, a simple interaction between the African, Arabian and Eurasian plates being insufficient for this purpose. It has been pointed out4,6 that recent developments in the theory of earthquake mechanism, most notably the concept of seismic moment<sup>6</sup>, enable determinations of the extent to which interactions between plates affect the rates of seismicity along their boundaries. Use of earthquake catalogues

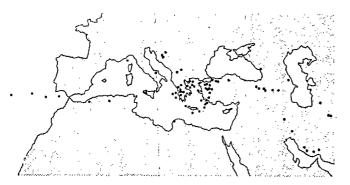

Fig. 1 Events for which seismic moment has been determined from Rayleigh wave spectral amplitudes.

for the first half of this century<sup>7.8</sup> may be combined with a magnitude-moment relation to extend the relatively short time interval for which reliable measurements of moment can be made (the last 10-15 yr), though such studies are necessarily subject to considerable error.

In spite of the large inaccuracies involved, a comparison<sup>5</sup> of relative motions between the major plates determined from seismicity over the last 70 yr with those calculated on the basis of plate tectonic theory from, for example, seafloor spreading evidence, indicated considerable agreement between the two. A notable exception to this was the western part of the Alpide Belt, where the calculated slip rate was considerably greater than that evidenced by the seismicity. In the present study accurate determinations of seismic moment have been made for all the larger ( $M_s > 5.5$ ) earthquakes in this region for the period 1963–70. These results have been used to construct a magnitude-moment relation for estimation of seismic slip between 1910 and 1970, for comparison with the rates of motion predicted by a plate tectonic model<sup>1</sup> for the region.

The latter extends from the Azores to eastern Iran (60E). The fault-plane solutions determined were used to compute the theoretical Rayleigh wave spectra for the 80 events (Fig. 1) large enough to have digitisable surface waves. The procedure adopted in the reduction of the surface-wave data is essentially that of previous workers 6.9.10. As the region studied is structurally very complex, considerable crustal and upper mantle variations will unpredictably affect the shorter periods, so observed and theoretical spectra are compared only in the period range 40–80 s

For three of the largest events, seismic moment has already been determined11,12 and these results are used here. Some of the larger shallow earthquakes in Turkey and Iran occurring before 1963 produced appreciable and well-documented surface displacements<sup>13,14</sup> from which moment may be estimated. In Fig. 2 all the moment values obtained are plotted against the corresponding surface-wave magnitude Ms. Shown on the same figure (dashed lines) are two magnitude-moment relations (B<sup>15,16</sup> and A<sup>17,18</sup>) calculated on the basis of scaling laws of the earthquake source. In the magnitude range  $6 \le M_s \le 7.5$  the relation used here is given by the solid line (C): it gives generally higher moment values than either A or B. For  $M_s > 7.5$  there is considerable disagreement between B and A as to the nature of the magnitude-moment relation: the data presented here do not convincingly favour either. Fortunately, all but one (Azores-Gibraltar region, November 25, 1941) of the higher magnitude events ( $M_s > 7.5$ ) in the area during 1910-60 were associated with surface displacements from which we may estimate moment (Fig. 2).

Relation C now permits calculation of the relative motion occurring along the major fault zones in the region considered. On the basis of the plates suggested, the Mediterranean and Middle East has been divided into 14 plate boundary 'segments' (Fig. 3 and Table 1). A search has been made through earth-quake catalogues<sup>7,19</sup> for the area and each event of  $M_s \ge 6$  assigned, wherever possible, to one of these boundary segments. For each event moment has been estimated and the moment sum for each segment calculated. We consider only the 60 yr

Segment numbers and plate names from Fig. 1. The predominant type of faulting is designated strike slip (S), thrust (T), normal (N) or mixed (M). N is the number of events for which moment has been summed and the next column gives the % of total moment contributed by the largest event.

\* From ref. 1.

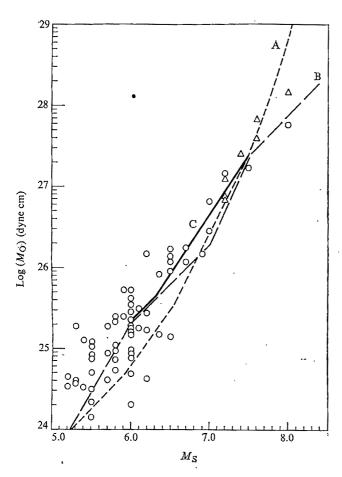

Fig. 2 Seismic moment as a function of magnitude for the events studied here (O) and for those for which moment could be estimated from surface faulting evidence (A). Also shown are the magnitude-moment relations A, B and C discussed in the text.

period 1910–70, mainly because before 1910 magnitude determinations were rarely instrumental and therefore likely to be unreliable. In Table 1 the moment sums for each segment over 1910–70 are given, together with those for 1964–70 during which moment measurements are reliable. Each has been reduced to a yearly rate and, as expected, these differ considerably, reflecting secular variations in seismicity.

For segment 1 two values are given, corresponding to a conversion of the magnitude of the large earthquake already mentioned to moment through relations B and A. The difference between the prediction of these models is very large: at  $M_s = 8.25$ ,  $M_o(A)/M_o(B) = 500$ . In Table 1 the number of events of  $M_s \ge 6$  (N) in each segment is given, together with the percentage of total moment contributed by the largest event; where this exceeds 50% the moment rate may well be a poor reflection of one based on longer term seismicity.

The rates calculated from the plate motions suggested are also given in Table 1. The relative yearly rates of motion  $(\nu)$  between these plates are obtained from the velocity vectors given and each is an average over the length L of the plate boundary segment. The depth D, to which faulting takes place is taken as 30 km except in mountainous areas (segments 5, 13, 14) where, by analogy with results for the Canoasus<sup>20</sup>, it is taken as 50 km. Seismic moment is defined as  $M_o = \mu u A$ , the product of the shear modulus  $\mu$ , (taken as  $3.3 \times 10^{11}$  dyne cm<sup>-2</sup>) the area of the faulting boundary A(=LD) and the mean relative displacement u. For a region of strike slip faulting the yearly moment rate is then  $M_o$  yr<sup>-1</sup> =  $\mu v L D$ . For areas of thrust or normal faulting, involving crustal shortening or extension,  $M_o$  yr<sup>-1</sup> =  $2\mu v L D/\sin\delta$  where  $\delta = 45^\circ$  is the average dip of the planes on which faulting takes place.

In the last column the ratio of the theoretical moment rate to the observed (equivalent to the ratio of slip rates) is given for the period 1910-70. For all but four of the segments, the percentage of moment contributed by the largest event is less than 50%, and so a ratio close to unity might be expected, on the basis of that observed elsewhere in the world<sup>5</sup>. This seems, however, to be the case only for segments 7, 8, and 9, and an alarming feature is that for no individual plate is there even reasonable agreement along all its boundaries. The best-known plate interactions, those of Africa-Eurasia and Arabia-Eurasia, show particularly poor agreement. It can reasonably be argued that observed and theoretical slip rates should be in closer agreement when the latter are large, as the seismicity should be higher and a shorter period of time sufficient. A comparison of the ratio of theoretical to observed slip rates with predicted slip rates (v) reveals that this is not the case. A curious feature is that the motions of the smaller plates such as the Aegean and Turkish, are, at least along some of their boundaries, close to those predicted.

The seismic slip rates obtained in this study are not only generally much less than those predicted by what seems to be a quite plausible model for the tectonics of this region, but are also far lower than those observed elsewhere. For the large magnitude earthquakes the moments can, with one exception, be estimated from surface faulting. In the magnitude range  $6 \le M_s \le 7.5$  the magnitude-moment relation derived predicts higher moment values than those given by relations A and B, and so these are likely, if anything, to be too high. The magnitudes themselves are unlikely to be systematically low and would need to be so by at least one unit to produce the discrepancies observed. Errors in the values chosen for the vertical extent of faulting and the shear modulus are unlikely to be more than 50%, and can hardly cause the considerable disagreement found.

The latest model<sup>1</sup> of the tectonics of this region is therefore not capable of verification by the methods described in this paper, on the basis of either present or past seismicity. No individual slip rate obtained is considered reliable enough to constitute a contradiction of the model, and in particular some of the boundaries of the minor plates are almost as active as predicted. If the earthquakes in this area are considered to result solely from an interaction between the Eurasian, African and Arabian plates, the observed seismicity rate is still an order of magnitude less than expected. None of the results obtained here contradict the existence of the smaller plates, which are in any event required to produce the complicated pattern of seismicity.

There are two possible causes for these large discrepancies. The first, and most obvious, is that 70 yr is not a long enough time for the seismic slip rates to agree with those calculated from the plate theory. If this were so, then one might expect, on the basis of the agreement found elsewhere<sup>5</sup>, that the ratios of observed to predicted slip rates would vary about unity. This is

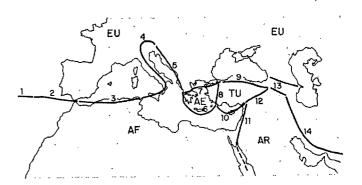

Fig. 3 Plate boundary segments to which events in this area were assigned. The plates shown are the Eurasian (EU), African (AF), Arabian (AR), Aegean (AE) and Turkish (TU).

not the case, this ratio being generally low. The most plausible explanation of the considerable discrepancies observed here is that a major proportion of the deformation in this area takes place in viscoelastic processes such as creep. This should be verifiable by the installation of strain/creepmeters in the regions where the disagreement between theory and observation is greatest.

This work was supported by a grant from the National Environmental Research Council. I thank the Shell International Petroleum Company for a scholarship.

### Submerged platform of marine abrasion around the coasts of south-western Britain

RECENT studies at Aberystwyth have shown that Palaeozoic rocks extend as a gently sloping platform (below a cover of sediment or drift) 16 km seawards of the coast of south-western Wales, up to 18 km to the south of the coast of Ireland, and some 15 km north-west of Cornwall. Sparker traverses1 show this platform to be, in general, smoothly planed with its outer margin descending to at least 80 m. Former islands, now submerged, occur; as, for example, in St. Bride's Bay and off Tuskar Rock. Westwards of the Camel estuary the platform continues unbroken across the fault which throws Cretaceous rocks against the Palaeozoic. Shorewards no definite submerged cliff line has so far been traced and in some cases at least, the cliff line may be coincident with the outer edge of the modern coastal platform, or even the modern cliff2.

A platform of this width, cut in resistant Palaeozoic rocks, can hardly have been cut during the successive low sealeyels of the Pleistocene, which occupied in total only a small proportion of Pleistocene time. The interglacial '10 foot platform' recognised in southern and western Wales<sup>3</sup>, Devon<sup>4</sup> and southern Ireland<sup>6</sup> forms only an insignificant nick in the coastal cliffs. Moreover, this platform, probably of Cromerian age<sup>6,7</sup>, runs into already formed estuaries and bays8, and was thus preceded by a period of lower sealevel. The St Erth Beds of late Pliocene age similarly occur9,10 on the side of a pre-existing valley. The broad submerged platform of marine abrasion is, therefore older than late Pliocene.

This gives the terminus ad quem, what of the terminus a quo? The Lenham Beds of south-eastern England occur as residual deposits on the tops of hills and must precede this period of lower sealevel and prolonged erosion. It is inconceivable that deposits coeval with the Lenham Beds would not have been found in the valleys of the Weald had those valleys been in existence and submerged by the Lenham sea. Equivalents of the Lenham Beds<sup>11</sup> found in borings in the Antwerp Kampen contain Upper Miocene foraminifera, confirming an opinion previously expressed by Voorthuysen12. The cutting of the submerged platform therefore occurred between Upper Miocene and late Pliocene times.

Evidence seems to favour an end Miocene or early Pliocene date. Gignoux<sup>13</sup> has remarked on the regression of latest Miocene time, which affected western Europe. The late Miocene (Messinian) desiccation of the Mediterranean postulated by Ruggieri<sup>14</sup> has been confirmed<sup>15</sup>. This event occupied 2 Myr according to the time scale of Berggren<sup>16</sup>. The platform must have been trimmed and trimmed again during the successive regressions and transgressions of the Pleistocene but its formation occurred much earlier. Likewise, submerged river valleys crossing the shelf17 are likely to be very old, having merely been scoured out during the last regression of the sea and refilled by Flandrian deposits.

Not the least surprising feature, if this hypothesis is true, is the remarkable stability of western Britain during this long period of time, contrasting so markedly with the activity of the marginal faults during the Oligocene and Miocene. The highlevel platforms of Wales, Cornwall and Ireland must necessarily have been formed in Oligocene and Miocene times, the submerged platform being simply the last of a series of erosional features occasioned by prolonged stillstands of the sea.

### 'Spectacle' array of <sup>210</sup>Po halo radiocentres in biotite: a nuclear geophysical enigma

POLONIUM radiohaloes occur widely and not infrequently (total about 10<sup>15</sup>–10<sup>20</sup>) in Precambrian rocks but their existence has so far defied satisfactory explanation based on accepted nucleocosmogeochemical theories<sup>1</sup>. Do Po haloes imply that unknown processes were operative during the formative period of the Earth? Is it possible that Po halos in Precambrian rocks represent extinct natural radioactivity<sup>2</sup> and are therefore of cosmological significance? A detailed comparison between an unusual array of Po halo radiocentres and U–Th halo radiocentres is presented here as bearing on the above questions.

Generally, radiohaloes occur in one of several mineralogical contexts<sup>1,3,4</sup>. First, as single haloes around discrete inclusions well isolated from other mineral defects and haloes; second, as single haloes around discrete inclusions lodged in conduits or cleavage cracks; third, as single haloes randomly spaced in clusters (sometimes overlapping); fourth, as vein haloes which formed from a continuous distribution of radioactivity (apparently deposited from hydrothermal solutions) along a conduit; and fifth, as line haloes, which surround, not conduits or cracks, but genuine single inclusions which are long (for example, 25 µm) compared with their width (perhaps 1 µm). Large, amorphous, coloured regions without discrete inclusions are not haloes.

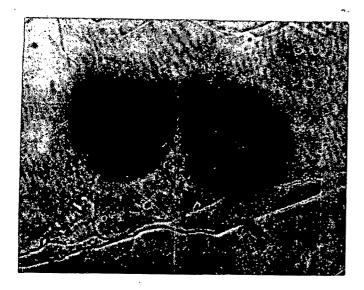

Fig. 1 'Spectacle' array of  $^{210}Po$  haloes in biotite. Halo radius,  $18.5~\mu m$ .

A striking exception<sup>1</sup> to this classification is the 'spectacle' coloration pattern (Fig. 1), which exhibits two almost circular rings of inclusions joined by a linear array of inclusions. As far as we know this is unlike any group of haloes previously seen. This geometrical arrangement of halo radiocentres, found in a Precambrian biotite from Silver Crater Mine, Faraday Township, Ontario, exhibits true radiohalo characteristics.

First, the coloration is identical to that of normal haloes found about 300  $\mu$ m away in the same mica specimen. Second, the three-dimensional nature of the halo pattern was demonstrated when the specimen (initially about 50  $\mu$ m thick) was cleaved; both halves revealed matching 'spectacle' coloration patterns, the only difference being the presence of the inclusion array in one half and its absence in the other half. Third, the radius of the coloration band (18.5  $\mu$ m) implied an origin from <sup>210</sup>Po  $\alpha$  decay. Mass spectrometric and X-ray fluorescence

methods were used to ascertain whether this was indeed a Po halo array.

Before applying these techniques to the 'spectacle' halo, we established that ion-microprobe mass analyses and scanning electron microscope X-ray fluorescence (SEMXRF) studies of 'normal' or 'standard' halo radiocentres (those formed from both U and Th  $\alpha$  decay) yielded data consistent with the visual means of identification. Several U-Th haloes (see, for example, photo insert, Fig. 2) found in a Precambrian pegmatitic mica from Rossi, New York, were analysed by X-ray and ion-probe techniques. Several U-Th halo radiocentres were chosen which contained only U, Th and Pb in any significant abundance, thereby virtually eliminating any molecular ion interference in the Pb-Th-U region (m/e = 204-238) in the ion probe.

That the mica matrix<sup>5</sup> yielded insignificant molecular ion currents in the region m/e = 160-320 is evident from the data in the lower portion of Fig. 2. In contrast, the recorded spectra of a U-Th inclusion (upper left portion of Fig. 2) revealed a significant number of ion counts accumulated in 12 passes of the regions m/e = 204-209 and (with a different scale) m/e = 232-240. Total ion counts are tabulated just above the two spectra. The scans on the Pb-Bi region (m/e = 204-209) lasted for several minutes and were taken before the scans (equal time) on the U-Th region.

Exact  $^{208}\text{Pb}/^{238}\text{U}$  and  $^{208}\text{Pb}/^{232}\text{Th}$  ratios are not obtainable from the ion count data in Fig. 2 because variable U and Th concentrations were observed as the ion probe beam sputtered away the inclusion; accurate ratios could be obtained by simultaneously accumulating counts in the region 204–238 provided that the greater secondary ion yield of U and Th as compared with Pb is taken into account. On the other hand, the separate Pb and U isotope ratios are meaningful. Note, for example, that after subtraction of background counts at m/e = 240 from the total counts at m/e = 235 and 238, the 235/238 value (0.76) satisfactorily approximates (considering the relatively small number of counts collected) the natural U isotopic ratio,  $^{235}\text{U}/^{236}\text{U} = 0.72$ . The absence of a peak at 204 shows there is little or no common lead in the inclusion and therefore, that the 206/207 ratio is that of  $^{206}\text{Pb}/^{207}\text{Pb}$  as derived from in situ U decay.

Also shown in Fig. 2 are the SEMXRF spectra of the mica matrix and the U-Th halo radiocentre, both of which correlate well (with the exception of the low Z and low abundance elements in the former) with the respective ion-probe spectra. Only U, Th and Pb are exclusively in the inclusion.

The ion-microprobe mass spectrum of the mica matrix surrounding the 'spectacle' halo was nearly identical to the mica spectrum shown in Fig. 2 and is not repeated in Fig. 3. Figure 3 (top centre) shows the portion m/e = 160-264 of the ion-microprobe spectrum (verical log scale) of several of the inclusions. Also shown is the actual ion-probe trace of the important region from m/e = 204-210 using a linear vertical scale and an expanded horizontal scale. There is no significant ion current above m/e = 209; that is, no significant ion signals were detected at any of the prominent U and Th peaks:  $238(U^+)$ ,  $254(UO^+)$ ,  $232(Th^+)$  and  $248(ThO^+)$ . No m/e = 204 was detected above background (1 c.p.s.), and the 206/207 mass ratio was  $\approx 20$  (206 signal  $\approx 2,000$  c.p.s.).

Figure 3 also shows SEMXRF spectra of the surrounding mica and of one of the Po halo radiocentres. Lead is the only element detectable in this radiocentre exclusive of the mica; some adjacent radiocentres revealed Bi as well. The use of two different instruments, and longer counting times, account for the slightly different X-ray spectra in Figs 2 and 3. The excellent resolution of the SEM showed the Pb-rich areas to coincide exactly with the Po halo radiocentres which are visible both in ordinary transmitted (Fig 1) and reflected light microscopy. Regions as close as 1 µm to the radiocentres showed virtually no Pb or Bi, implying little if any diffusion loss from the inclusions.

As the X-ray data definitely show Pb (and sometimes Bi) in the 'spectacle' halo radiocentres, and as there is no evidence for any molecular ion contribution in the region from m/e =

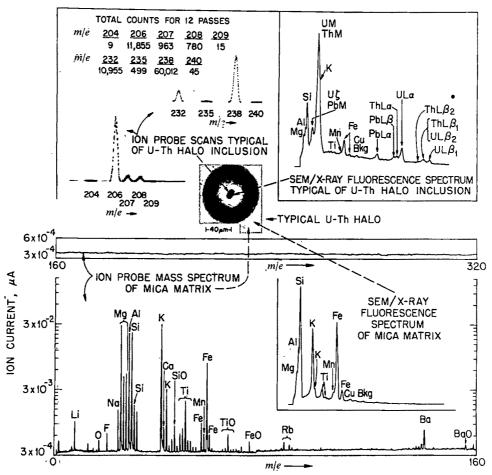

Fig. 2 Ion microprobe and XRF comparison between mica matrix and U-Th halo inclusion.

204–238, the 206, 207 and 208 peaks are interpreted as Pb isotopes and 209 as <sup>209</sup>Bi. <sup>204</sup>Pb, a constituent of both common and primordial Pb, is missing (no 204 peak), implying that the 'spectacle' halo inclusions analysed contained no detectable Pb

of either of these types. Absence of the 232, 235 and 238 peaks is interpreted as showing the inclusions contain virtually no <sup>232</sup>Th, <sup>235</sup>U or <sup>238</sup>U and, therefore, no radiogenic <sup>208</sup>Pb, <sup>207</sup>Pb or <sup>206</sup>Pb derived from the *in situ* decay of these isotopes. The 207 and 208

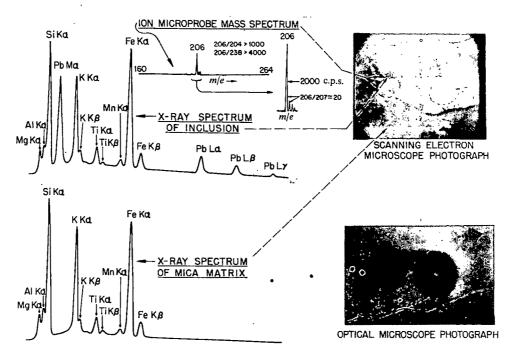

Fig. 3 Ion microprobe and SEMXRF spectra of mica matrix and 210Po halo inclusions.

peaks are therefore attributed to 207Pb and 208Pb, perhaps arising from the decay of minute amounts of 211Bi and 212Bi within the inclusions<sup>5,6</sup>. The <sup>209</sup>Bi is considered to be primordial.

The outstanding feature of the mass analysis is the prominent 206 signal which, when attributed to the presence of 206Pb in the inclusions, fits perfectly with the prediction based on ring structure measurements, that is, that the 206Pb is radiogenically derived, not from U or Th, but directly from 210Po a decay. In this respect, the large difference in the 206/238 (208Pb/238U) ratio between the 'spectacle' halo and the U-Th halo (Figs 2 and 3) is especially significant. Clearly the 'spectacle' halo resulted from <sup>210</sup>Po α decay; an explanation for its geometry is still under study.

Because the Pb isotope in these inclusions is not explicable as any combination of common, primordial, or from in situ Pb derived radiogenically in situ from U or Th, we conclude that a different type of Pb, derived from Po a decay, exists in nature. Supportive evidence comes from electron-probe and ion-probe analyses of a 218Po halo radiocentre found in a mica from the Iveland District, Norway, which yielded a 206Pb/207Pb ratio of 23. This is consistent with that expected from <sup>218</sup>Po a decay to <sup>206</sup>Pb. Such a Pb ratio is impossibly high based on normal isotopic <sup>238</sup>U/<sup>235</sup>U decay, the theoretical maximum being 21.8.

Other investigations have shown varying mixtures of Uderived and Po-derived Pb may occur in the same radiocentre. for there exists an almost continuous halo spectrum stretching from 'pure' U to 'pure' Po haloes. Only a few (<0.01) Po haloes in biotite may survive the delicate sectioning process necessary for SEM X-ray analysis.

Just as important as the existence of a new type of lead is the question of whether Po haloes which occur in a granitic or pegmatitic environment (for example, in mica, fluorite or cordierite) can be explained by accepted models of Earth history1. (R. V. G. has found other 210Po haloes that differ essentially from those in granites—unpublished information.)

### **Gravitational driving** and energy of Adriatic tides

In small semiclosed seas, tides are excited through their open boundaries by the tides in the more extensive bodies with which they 'co-oscillate'1-6. Nevertheless the energy dissipated in such seas is not necessarily advected from and lost by, the larger system<sup>5</sup>.

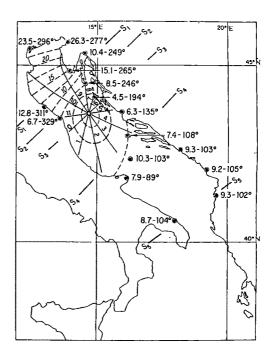

In elongated gulfs opened to the ocean, such as the Bay of Fundy and the Gulf of California, exceptionally high tides may occur. In these two cases advection of energy from the ocean largely exceeds direct gravitational forcing<sup>6,7</sup>. The opposite situation may, however, also be encountered.

Although not spectacular, the tides in the Adriatic, which at the head reach 26 cm for the main semidiurnal constituent (M2) and 18 cm for the main diurnal constituent (K1), are also remarkable in view of the modest tidal amplitudes of the adjacent Ionian Sea (6.5 cm for M2 and 1.5 cm for K1)3. Semidiurnal dissipation in the Adriatic must be low because of the effect of small amplitudes upon the faster than linear dependence of friction on velocity.

Although a square law frictional dependence must play an important role in reducing the tendency to dissipate at low amplitudes, inspection of the patterns of phases and amplitudes for M2 (cotidal and corange maps) suggests that the tidal flow is substantially in phase with the gravitational forces over most of the Adriatic. Thus, positive semidiurnal energy must be received directly from the gravitational forces balancing part or all of the frictional loss (Figs 1 and 2).

I believe that the Adriatic receives more than the energy it dissipates directly from gravitation at lunar semidiurnal frequency (M2). This conclusion is supported by calculations of energy budgets (see ref. 7) for the entire Adriatic, based on the ensemble of available observations, and a qualitative extension of considerations<sup>5</sup> about the position dependence of amphidromes (points of zero tide) upon dissipation.

Considering units of area transverse to the Adriatic, the

direct gravitational energy flux,  $E^{s}$ , is the sum of individual contributions according to

$$E^{s} = \sum_{n=1}^{n} \langle T_{n} F_{n} \Delta l_{n} \rangle \tag{1}$$

where  $T_n$  is volume transport across element n, covering distances  $\Delta l_m$ ; and  $F_n$  is the force which produces the gravitational tide.

The transport  $T_n$ , or volume crossing section n in a unit time equals the amount added to the prism  $P_n$ ; the latter represents the volume of water above mean sealevel to the head of section n, with

$$P_n = \sum_{n=1}^n H_n \Delta A_n, \quad T_n = \mathrm{d}P_n/\mathrm{d}t \tag{2}$$

where  $H_n$  is tidal elevation; and  $\Delta A_n$  is the horizontal area of section n. Thus,  $T_n$ , the time derivative of  $P_n$ , is 90° ahead of  $P_n$ .

 $P_n$ . The results (Table 1) indicate that over the major part of the Adriatic T remains close to its maximum value, occurring in the amphidromic area, and that it conserves nearly the same phase  $\Phi_T$ , a lag of roughly 195° or 6.5 h. (Phases are referred to 15° E advance at an angular speed of  $\omega^{M2}=2\pi/12$  radians, or 30°, per lunar hour).

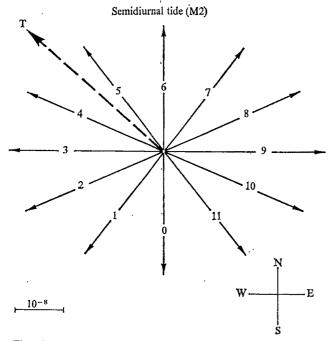

Fig. 2 Hourly variation of magnitude and geographical orientation of the Earth's surface slope with respect to equipotential surfaces for M2. T, direction of transport.

The tidal forces F (see equation 1) derive from the generating potential of the gravitational tide, W, according to

$$F = - \bar{\nabla} W \tag{3}$$

with, for the semidiurnal tide

$$W^{SD} = \rho g G^{SD} \cos^2 \theta \cos Z \tag{4}$$

where  $\overline{\nabla}$  is the horizontal gradient symbol;  $\rho$  is the specific mass of sea water; g is the acceleration of gravity;  $G^{SD}$  is the constant characteristic of each semidiurnal constituent;  $\theta$  is latitude and Z the hour angle, or longitude of lower transit of celestial body of interest—the Moon for constituent M2.

On a rigid Earth,  $G^{\text{SD}}$  for the semidiurnal constituent M2 is equal<sup>8</sup> to 24.3 cm. The elastic response of the Earth, however, depresses the tide potential by the factor (1-h+k), where h and k are the Love numbers characterising h, the solid Earth's response, and k, the resulting potential contribution<sup>9</sup>. Thus, the effective size of  $G^{\text{SD}}$  is reduced. The value (1-h+k)=0.69 has been taken, leading to  $G^{\text{SD}}=16.8$  cm for M2.

The hour-by-hour variation in magnitude and direction of the tidal slope over the Adriatic is shown in Fig. 2, together with the main geographical direction of transport—the Adriatic axis—and its phase.

Energy is supplied to the Adriatic tide when the tidal force component along the axis has the same direction as the transport. Work is done against the Moon in the opposite case. Over a tidal cycle both situations are encountered, but the gain exceeds the loss (Table 1). That can be visualised in Fig. 2.

The time-averaged influx of M2 gravitational energy is estimated at  $2.0 \times 10^{14}$  erg s<sup>-1</sup>. The main uncertainties are related to the coarseness of the integration scheme, neglect of motions transverse to the Adriatic, uncertainty on (1-h+k), and the possible influence of distortion of the Adriatic Basin through loading by the tide itself. The importance of transverse motion is commensurable with the minor-major axis ratio of the elliptical trajectories of the water particles if appropriate allowance for phase relationships is made. This all indicates an overestimation of  $E^{\mathfrak{p}}$  by a maximum of 20%. The cumulated uncertainty on the remaining factors could hardly exceed 20%. Thus, the M2 Adriatic tide receives, on an average,  $1.2-2.45 \times 10^{14}$  erg s<sup>-1</sup> directly from lunar gravitation.

Alternatively, advective driving by the Mediterranean tide is readily calculated by the flux method<sup>7</sup> according to the relationship:

$$E^{a} = \frac{1}{2} \rho g T H \cos \Phi_{T,H} \tag{5}$$

where T and H are volume transport and elevation, respective at the Adriatic-Mediterranean boundary; and  $\Phi_{T,H}$ , is the p difference between the two. Using the section between H and Durazzo, for which H is precisely known, as a boundary; and H is precisely known, as a boundary equation (2) has led to  $T = 1.6 \times 10^{11}$  cm<sup>3</sup> s<sup>-1</sup> and

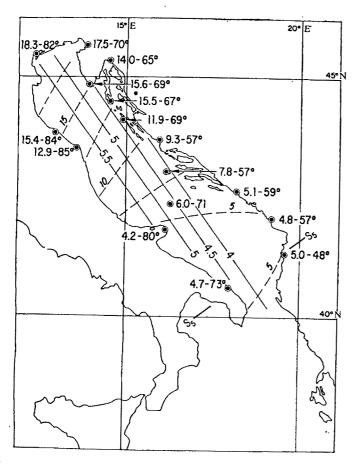

Fig. 3 Cotidal and corange map of the Adriatic for the diurnal constituent K1.

 $-98^{\circ}$ , resulting in  $E^a = -10^{14}$  erg s<sup>-1</sup>. Thus, on the average, M2 energy is advected from the Adriatic to the Mediterranean. This fact not only confirms, but indirectly requires that gravitational energy be supplied to M2 tidal motions of the Adriatic.

It should be pointed out that T and  $\Phi_{T,H}$  and, therefore, Ea, are dependent on consideration of effects from the island cluttered north-eastern shore, and on selected cotidal and corange patterns. I have, therefore, taken careful account of island areas and optimised cotidal and corange maps. Those which I selected, based on Defant's data3 (Fig. 1), do not differ significantly from those of Polli<sup>10</sup> which include more recent observations,

Estimates of tidal patterns show that displacement of the amphidrome toward the south-west reduces the energy flow to the Mediterranean. The sign changes for a 15 km displacement. Incompatibilities with the observations become noticeable, however, with a displacement of 7.5 km. Similar difficulties occur for north-eastward displacements of the order of 5 km. The energy transfer from the Mediterranean to the Adriatic thus falls between  $-0.4 \times 10^{14}$  and  $-1.4 \times 10^{14}$  erg s<sup>-1</sup>.

When the tide in a channel of constant cross-section can be represented by the sum of incident and reflected Kelvin waves with all the dissipation occurring in the reflection area, then amphidromic systems are formed with centres to the left of the axis in the northern hemisphere (the observer facing the head)5. This is valid in more general cases where dissipation also occurs along the channel. In such a case, however, the mathematical expression must differ.

In the Adriatic the evidence is for an amphidromic system very slightly displaced to the right rather than to the left (Fig. 1). This is even more evident if the north-eastern boundary is represented by a line displaced offshore from the main coastline in order to account for significant island area lost by the Adriatic Sea. Thus, here again, tidal energy loss from the Adriatic to the Mediterranean is implied.

Because conservative error bars have been accepted for E. without providing for a possibility of advective energy flow toward the Adriatic, and because independent estimates of  $E^{z}$ , which are not sensitive to small changes in cotidal and corange maps, support the same conclusion, there must be a gain of direct semidiurnal gravitational energy.

Because of the uncertainty on both  $E^a$  and  $E^g$ , frictional dissipation within the Adriatic is not well established. It may fall anywhere between zero and 2.05  $\times$  10<sup>14</sup> erg s<sup>-1</sup>.

Tidal patterns for the main diurnal constituent, K1, are proposed on Fig. 3. Hour-by-hour variation of the gravitational slope can be derived from the diurnal potential:

$$W^{D} = \rho g G^{D} \sin 2\theta \cos Z \tag{6}$$

Treatment of the K1 tide along the same lines as the M2 tide shows that direct gravitational driving,  $E^{s} = -0.3 \times 10^{14}$ erg s<sup>-1</sup>,  $\pm 50\%$ , is negative but negligible compared with the energy influx through the Mediterranean boundary,  $E^a$  $4 \times 10^{14}$  erg s<sup>-1</sup> ( $\pm 20\%$ ). Dissipation for K1 falls between 2.85 and  $4.75 \times 10^{14}$  erg s<sup>-1</sup>. Thus, it is appreciably higher than for M2, in spite of the greater amplitude and higher frequency of the

Two factors peculiar to the Adriatic play an important role in its tidal behaviour: first, the closeness of its natural resonance to tidal frequencies, and second, the phase relationship between advective and gravitational driving. The interplay between these two factors allows semidiurnal tidal currents to flow downslope with respect to equipotential surfaces most of the time, and over most of the Adriatic, permitting the tide to gain appreciable energy in spite of the small size of the gravitational forces.

The closeness of the Adriatic to resonance is dramatically illustrated by the vulnerability of Venice to flooding<sup>10,11</sup>. The Adriatic's response to storms commonly results in oscillations -seiches-with near tidal periods which, combining with the tide, create catastrophically high waters—aqua alta. The near diurnal seich, with a period of about 22 h (ref. 10) is by far the most devastating. A near semidiurnal seiche is also observed, with a period around 11 h. Most of its energy escapes, however, into the Mediterranean in much the same manner that direct gravitational energy flux at semidiurnal frequency also leaks away. Thus, the highly damped near semidiurnal seiche has less disastrous effects.

Independent verification of the importance of direct gravitational driving of the Adriatic could be made by two approaches: mathematical modelling—analytical<sup>12</sup> or digital—and experimental investigation. Sufficiently precise positioning of the amphidrome would provide a useful, though mainly qualitative, answer. There are, however, difficulties resulting from the vanishing of the signal at the point of interest13. Alternatively, precise estimates of energy exchanges between the Mediterranean and Adriatic could be obtained by adequate current measurements through the Straits of Otranto.

### Transition to CP conservation and zero Cabibbo angle in strong magnetic fields

Most current theories of particle symmetries assume that violations of these symmetries come about through a spontaneous breaking mechanism which produces non zero expectation values for certain scalar (elementary or composite) fields. As is well known (refs 1-7 and Lebedev Institute Reprint No. 101) these expectation values may make a phase transition to a zero value for certain critical temperatures and possibly also for certain critical external magnetic field strengths  $H_c$ ,  $H_{e_1}, H_{e_2}, \ldots$  Here we point out that it is conceivable that the charge asymmetry (associated with CP violation) in  $K_L \rightarrow \pi^{\pm} +$  $l^{\pm}+\bar{\nu}(\nu)$  decays may disappear for fields of  $\sim 8\times 10^{10}$ gauss if CP violation is milli-weak in character, and that the Cabibbo angle may be reduced to zero—leading to suppression of certain hyperon decays—in fields of the order of 10<sup>16</sup> gauss. These estimates are so strongly model-dependent that it may be worthwhile in any case, to make a systematic phenomenological search for effects on particle asymmetries of strong magnetic fields of 10<sup>8</sup> gauss upwards.

The notion of critical fields (above which spontaneously broken symmetries are restored) is well known from the Ginzburg-Landau theory of superconductivity which is also the prototype of spontaneous symmetry-breaking mechanisms used in particle physics. An order of magnitude estimate of the critical field  $H_c$  in this theory is provided by considering the free energy:

$$F = F_n + \alpha(T)|\varphi|^2 + \frac{\lambda(T)}{2}|\varphi|^4 + \dots$$
 (1)

where n denotes normal.

For temperature  $T < T_c$ , F has a minimum when

$$|\langle \phi \rangle|^2 = -\alpha/\lambda \tag{2}$$

The 'thermodynamic' critical field close to  $T_c$  is then given by 8:

$$\frac{H_{c}^{2}(T)}{8\pi} = F_{n} - F_{s}$$

$$= \frac{1}{2} \frac{\alpha^{2}}{\lambda}$$

$$= \frac{1}{2} \lambda |\langle \varphi \rangle|^{4}$$
(3)

where s denotes superconducting.

Now in superconductivity theory the (Cooper-pair) field  $\varphi$  is itself charged and the magnetic field interacts directly with it. For K<sup>0</sup> fields (which we wish to investigate here) this is not the case. In an SU(3)-symmetric theory, however, the magnetic field does interact in higher order loop graphs. To see the qualitative emergence of a formula like equation (3), we later consider (for T = 0) an O(3)-symmetric gauge model, where the electromagnetic field is part of a gauge-triplet. Even though we are not dealing with a thermodynamic system, a critical field  $H_c$  seems to exist in a one-loop approximation above which the

expectation value of the neutral field  $\langle \phi_3 \rangle$  vanishes—the relationship between  $H_c$  and  $\langle \varphi_3 \rangle$  having the general form of equation (3). Here we shall use this formula for order of magnitude estimates. Clearly  $H_c$  will be small for those situations where  $\langle \varphi \rangle$  and  $\lambda$  are small.

Now for strong interaction symmetries like SU(2) or SU(3), values of  $\langle \varphi \rangle$  are typically ~ BeV •(or somewhat less), with  $\lambda \simeq 1$ . But for weak interaction symmetries—and these provide the more spectacular physical situations—with universal gauge coupling of order unity  $(g^2 \approx 4\pi/137, g \approx 1/3), \langle \phi \rangle$  values are typically tens or hundreds of BeV in magnitude, except for 'off-diagonal' situations. By way of illustration we consider the  $\langle \varphi \rangle$  associated with real rotations of the n-A system (Cabibbo angle) and ⟨φ⟩ associated with complex rotations which signal CP violation in a milli-weak manner.

To estimate the magnitude of  $H_c$  for these cases, assuming that it exists we consider the ideas of Lee<sup>9</sup>, Pais and Primack<sup>10</sup> or Mohapatra and Pati (ref. 11 and University of Maryland Technical Report No. 74-085). In their milli-weak theory, the latter authors write the mass matrix for the n, A quark system in the form:

$$f(\overline{\mathbf{n}}, \overline{\Lambda})_{\mathbf{L}} U_{\mathbf{L}} \begin{bmatrix} m_{\mathbf{n}} & 0 \\ 0 & m_{\Lambda} \end{bmatrix} V_{\mathbf{R}}^{-1} \begin{bmatrix} \mathbf{n} \\ \Lambda \end{bmatrix}_{\mathbf{R}}$$
(4)

where  $U_L$  and  $V_R$  are matrices of the type:

$$\begin{vmatrix} \cos \theta_{L,R} & -\sin \theta_{L,R} \exp(i\delta_{L,R}) \\ \sin \theta_{L,R} \exp(i\delta_{L,R}) & \cos \theta_{L,R} \end{vmatrix}$$
 (5)

with  $\theta$  and  $\delta$  real. The real part of the off-diagonal elements of the expectation-value matrix

$$U_{L} \begin{vmatrix} m_{n} & 0 \\ 0 & m_{A} \end{vmatrix} V_{R}^{-1}$$

(assuming for simplicity  $\theta_L = \theta_R$ ) is given by:

$$\frac{1}{2}(m_{\Lambda}^{2}-m_{N})\sin 2\theta_{c}\cos(\epsilon/2) \tag{6}$$

where  $\delta_L = \epsilon/2$ ,  $\delta_R = -\epsilon/2$ . Now from CP violation,  $\epsilon$  in this model can be as small as  $2 \times 10^{-3}$ . With  $m_{\Lambda} - m_{N} \simeq 175$  MeV,  $\theta_c \sim 15^\circ$  and assuming f in equation (4) to be typically  $\simeq 1$ , we obtain:

$$\text{Re}\langle \phi \rangle |_{\text{off-diagonal}} \simeq 45 \text{ MeV}$$
 (7)

Using equation (3) and making the ad hoc assumption that the numerical constant  $(\lambda)$  appearing there is of order unity, we obtain

$$H_c \simeq 3 \times 10^{16} \text{ gauss}$$
 (8)

(using the conversion  $\langle \varphi \rangle$  (MeV) = 0.3H (kgauss) cm).

If fields of this magnitude are applied, the real part of the 'off-diagonal' expectation value may vanish and, with it, the Cabibbo angle, suppressing certain hyperon and strange-particle

Also, the imaginary part of the off-diagonal matrix element of the mass matrix is

$$(f/2)(m_{\Lambda}+m_{\rm N})\sin 2\theta_{\rm c}\sin \epsilon$$

This expectation value may make a transition to a zero value for fields  $H_{\rm c} \simeq 10^{14}$  gauss—and with it the (milli-weak) •CP asymmetry—for a heavy quark model  $(m_{\Lambda} \sim 5 \text{ BeV})$ ; for a light quark model  $(m_{\Lambda} \sim 300 \text{ MeV})$ , on the other hand,  $H_c$  may reduce to 8  $\times$  10<sup>10</sup> gauss.

(A preliminary and perhaps unrealistic model for spontaneo superweak CP breaking seems to give a value of arc  $3 \times 10^6$  gauss for the critical field strength. This is likely a very gross—though morale-building—underestimate the experimental point of view.)

Since in these estimates we have assumed, for simplicity, that all model-dependent constants like f and  $\lambda$  are  $\sim$  unity and, further, since equation (3) itself is a very crude estimate, it is clear that  $H_c$  may change by orders of magnitude, and also not one but a hierarchy of critical fields may be discovered when a detailed investigation is carried through. This situation is not unfamiliar in superconductivity theory, where, depending on the ratio of the parameters  $\lambda$  and g (the gauge coupling), superconductors are divided into Type I and Type II, with Type II displaying a variety of critical fields<sup>12</sup>  $H_c$ ,  $H_{c_1}$ ,  $H_{c_2}$ ,  $H_{c_3}$  and a corresponding variety of physical (vorticity) characteristics (For V<sub>3</sub>Ga, for example, there are three widely differing critical fields,  $H_{c_1}$  (T=0)  $\simeq$  200 gauss,  $H_c$  (T=0)  $\sim$  6,000 gauss, and  $H_{c_2}$  ( $T\simeq 0$ ) which is as large as 300,000 gauss.)

Detailed models, in which we shall investigate the analogues of fields  $H_{c_1}$ ,  $H_{c_2}$ , ... for particle physics, will be considered elsewhere.

Fields of strength  $\sim 10^5$  gauss are possibly technically feasible for use in conjunction with K-beam experiments. Clearly, in order to test the ideas expressed here, stronger fields will be needed. There is no doubt, however, that if the basic ideas of spontaneous symmetry breaking are correct and if we believe in the validity of extrapolating from the one-loop calculation presented later, then there would exist critical fields for which the broken symmetries are likely to be restored. The future task of the theory is to explore such situations where the field strength required is not excessively intense and within reach of the forseeable technology. Since it is commonly assumed that the mean magnetic fields in pulsars are  $\simeq 10^{12} \simeq 10^{14}$  gauss, it would seem—for what it is worth—that CP-violating phenomena do not take place in pulsars, though the Cabibbo angle is still non-zero.

To illustrate the effect of a uniform magnetic field on symmetry breaking, we give a simple model calculation. A Lagrangian which exhibits local O(3) symmetry is given by:

$$\mathscr{L} = \frac{1}{4} F_{\mu\nu}{}^2 + \frac{1}{2} (\nabla_{\!\mu} \phi)^2 + \frac{\mu^2}{2} \phi^2 - \frac{\lambda}{4} (\phi^2)^2$$

where the scalar and vector fields,  $\phi$  and  $A_\mu,$  are triplets with respect to the O(3) symmetry and the covariant derivatives which appear are

$$\nabla_{\mu} \phi = \partial_{\mu} \phi + e \mathbf{A}_{\mu} \times \phi$$

$$\mathbf{F}_{\mu\nu} = \partial_{\mu} \mathbf{A}_{\nu} - \partial_{\nu} \mathbf{A}_{\mu} + 2e \mathbf{A}_{\mu} \times \mathbf{A}_{\nu}$$

The parameters  $\mu^2$  and  $\lambda$  are both positive: this implies a symmetry breakdown,  $O(3) \rightarrow O(2)$ , in the tree approximation. The vacuum expectation value of  $\phi$  is non-vanishing, and indeed, may be used to define a direction in iso-space

$$\langle \phi^i \rangle = \sqrt{(\mu^2/\lambda)} \delta^{13}$$
.

The corresponding component of the gauge potential,  $A_{\mu}^{3}$ , does not acquire a mass and so may be identified with the electromagnetic potential. In the tree approximation the presence of an external background electromagnetic field,  $\langle A_{\mu}^{3} \rangle \neq 0$ , has no influence on the expected value of the neutral component  $\langle \phi^{3} \rangle$  of the matter triplet.

When quantum corrections are taken into account this is no longer true. Already, the one-loop corrections to the effective action, given formally by:

$$\Gamma_{(1)}(\varphi,A) = (\hbar/2i) \operatorname{lnDet} G_{(0)}(\varphi,A)$$

(where  $G_{(0)}$  denotes the set of classical propagation function for small disturbances on a given background) imply a coupling between  $\varphi^3$  and  $A_{\mu}{}^3$  even when the charged components  $\varphi^{1,2}$  and  $A_{\mu}{}^{1,2}$  are set equal to zero in the modified ground state,

In the uniform magnetic background, where all fields vanish

except for

$$\varphi^3(x) = \psi$$
,  $A_1^3(x) = \frac{1}{2}Hx_2$ ,  $A_2^3(x) = -\frac{1}{2}Hx_1$ 

with  $\psi$  and H constant, the one-loop contribution to the effective potential,  $V_{(1)}(\psi,H)$ , is determined approximately by the differential formula

$$2\frac{\partial V_{(1)}}{\partial \psi^2} = \frac{\lambda h}{8\pi} \int_0^\infty \frac{\mathrm{d}s}{s} \left[ \left\{ \frac{eH}{\sinh(seH)} \exp\left[ -s(\lambda \psi^2 - \mu^2) \right] - \frac{\exp\left[ -s(\lambda M^2 - \mu^2) \right]}{s} \left( 1 - s\lambda(\psi^2 - M^2) \right) \right\} + \frac{3}{2\pi s} \left\{ \exp\left[ -s(3\lambda \psi^2 - \mu^2) \right] - \exp\left[ -s(3\lambda M^2 - \mu^2) \right] \times \left( 1 - 3s\lambda(\psi^2 - M^2) \right) \right\} \right]$$

(This expression is renormalised at H=0,  $\psi=M$ , that is,  $\partial V_{(1)}/\partial \psi^2$  and  $\partial^2 V_{(1)}/\partial (\psi^2)^2$  both vanish at this point.) The formula is approximate because we have not included the contributions due to intermediate vectors. The term with the H-dependent factor here is the contribution to  $V_{(1)}$  of the intermediate charge pair  $\phi^{1,2}$ , whereas the H-independent factor is due to the neutral  $\phi^3$ .

To determine the critical field, we should set  $\psi=0$  and require that  $2\partial V_{(1)}/\partial \psi^2|_{\psi=0}$  should compensate the tree contribution  $2\partial V_{(0)}/\partial \psi^2|_{\psi=0}=-\mu^2$ . Unfortunately, the neutral particle contribution to  $\partial V^{(1)}/\partial \psi^2$  is complex if  $\psi^2<\mu^2/3\lambda$ . This means that our approximation is inadequate. The source of this complexity is easily traced.

In restricting ourselves to one-loop effects we are not allowing the magnetic field to act on the neutral intermediate particles. Hence when  $\psi=0$  these appear to carry imaginary mass,  $i\mu$ . The very object of the computation  $\partial V/\partial \psi^2=0$ , is however, the setting to zero of the neutral particle mass. Clearly, we should be setting up a self-consistent (Dyson) equation: which means bringing in the contributions of higher loops. (For a similar pathology in a calculation of critical temperature see the paper of Dolan and Jackiw<sup>5</sup>.) Short of this, we can obtain an order of magnitude idea of the critical field by setting both  $\mu$  and  $\psi$  to zero specifically in the above expression for  $\partial V_{(1)}/\partial \psi^2$ . That is, we solve the restricted problem

$$0 = -\mu^{2} + \frac{\lambda h}{8\pi} \int_{0}^{\infty} \frac{\mathrm{d}s}{s} \left[ \left\{ \frac{eH_{c}}{\sinh(seH_{c})} - \frac{\exp(-s\lambda M^{2})}{s} \left(1 + s\lambda M^{2}\right) \right\} + \frac{3}{2\pi s} \left\{ 1 - \exp(-3s\lambda M^{2}) \left(1 + 3s\lambda M^{2}\right) \right\} \right]$$

or

$$\frac{\mu^2}{M^2} = \frac{\lambda^2 \hbar}{8\pi} \int_0^\infty \frac{\mathrm{d}u}{u} \left[ \frac{eH_c/\lambda M^2}{\sinh(ueH_c/\lambda M^2)} - \exp(-u) \left( \frac{1}{u} + 1 \right) + \frac{3}{2\pi} \left\{ \frac{1}{u} - \exp(-3u) \left( \frac{1}{u} + 3 \right) \right\} \right]$$
$$= \frac{\lambda^2 \hbar}{8\pi} \left[ a + b \frac{eH_c}{\lambda M^2} \right],$$

where

$$a = 1 + \frac{9}{2\pi}$$
 and  $b = \int_0^\infty \frac{d\nu}{\nu} \frac{d}{d\nu} \left( \frac{\nu}{\sinh \nu} \right)$  
$$\approx 2.5$$

On choosing the reference mass equal to  $\mu$  we obtain

$$H_{c} = \frac{1}{b} \left( \frac{8\pi}{\lambda^{2} h} - a \right) \frac{\lambda \mu^{2}}{e}$$

$$= \frac{1}{b} \left( \frac{8\pi}{\lambda^{2} h} - a \right) \frac{\lambda^{2} \langle \phi \rangle^{2}}{e}.$$

Since b is negative, we must have  $\lambda^2 H > 8\pi/a$ .

This estimate of  $H_c$  should not be taken as anything more than a rough indication. The form of this expression for  $H_c$ is basically similar to equation (3), apart from the numerical factor multiplying  $\langle \phi \rangle^2$ . It is factors of this type which in a realistic calculation may drastically alter the order of magnitude estimates given earlier. Also, for a situation involving a number of non-zero  $\langle \varphi \rangle$ s, one may conjecture that  $H_c$  would be an expression involving a sum of terms like  $\langle \Sigma f_i \phi_i \rangle^2$  with sequences of opposing signs among the coefficients  $f_i$ . This, in turn, may lead to the desired diminution of the absolute magnitudes of the critical field strengths.

It is perhaps worth remarking that the calculation presented above for the critical field does not constitute a general proof that such fields always exist. This problem clearly needs further study.

We thank Professor D. J. Bradley for pointing out that fields of 10<sup>8</sup> gauss in a small volume ~ 10<sup>-8</sup> cm<sup>3</sup> lasting more than 10<sup>-9</sup> s may conceivably be produced by laser compression techniques (though improvements in laser technology could permit the extension of both volume and duration) and to Dr Delbourgo for the remark that laser compression would also be accompanied by a high temperature which may help to produce the critical magnetic field at the same time. There is the further possibility that the electromagnetic energy pumping by the laser beam may by itself achieve the same purposes as are described in this communication. Such laser beams would have to have enormous powers of  $\sim 10^{18} \, \mathrm{W \, cm^{-2}}$ .

### Heavy metal particle characterisation

THE aerial fallout of heavy metals downwind of the Avonmouth industrial complex has been well documented. Analyses of vegetation<sup>1</sup> and moss bags<sup>2</sup> show decreasing levels of lead, cadmium and zinc with increasing distance from the complex.

The precise nature of the heavy metal fallout, however, has been neglected although the chemical and physical state of a metal determine to a large extent its mobility in the soil and hence its availability to plants and animals.

We have, therefore, trapped air particulates and examined them by scanning electron microscopy, together with an energy dispersive Kevex X-ray analyser attached to a similar microscope. Thus it was possible to select particles down to approximately 1 µm diameter.

Air particulates were trapped on strips of adhesive aluminium tape mounted on aluminium backing plates, freely suspended at about shoulder height in the vicinity of the industrial complex, in comparable positions to those previously used1. After several weeks, 1-cm circles were cut from the tapes and mounted on electron microscope stubs. These were then vacuum coated with a thin layer of aluminium to prevent 'charging' under the microscope beam.

Debris trapped on the tapes ranged from small flies to spherical particles of less than 1 µm diameter. In particular, a large number of spherical particles (< 1 µm-10 µm) were observed under the light microscope. Because of their perfect symmetry, they were thought to be metallic droplets condensed from the vapour in furnace chimneys and flues (E. R. Buckle, and K. C. Pointon, unpublished). X-ray spectra of these particles, however, showed the majority of them to be constituted predominantly of silicon with associate sodium, potassium, calcium, iron, vanadium and titanium in varying amounts. A smaller number of particles had relatively large levels of iron. Similar spherical balls were observed on leaf samples from vineyards belonging to Long Ashton Research Station. Two apparently identical balls 3 µm diameter and about 15 µm apart on a leaf were analysed. The first gave the normal silicon type spectrum while the second showed only the Ka and KB iron peak with no other metals being identified (Fig. 1a and b).

The spectra of less regular particles were examined. Most were of the general silicon type (Fig. 1a) but a few rather more crystalline samples gave strong sulphur and calcium peaks (Fig. 1c). Others gave high sodium, chlorine or calcium peaks while one particle seemed to consist solely of sulphur. Of the three elements of most direct interest, that is, cadmium, lead and zinc, particles containing the latter were the most abundant (0.5-10 µm in diameter). These particles also contained silicon, calcium, potassium, sodium and sulphur (Fig. 1d). Other particles, however, were found to consist solely of zinc and sulphur (Fig. 1e). The Kevex energy dispersive detector does not detect oxygen which may or may not be present in these particles.

Lead occurred much less frequently than zinc, but was generally in particles in the 50-100 µm range. It was found associated with small amounts of zinc and cadmium (Fig. 1f). Cadmium was found only in isolated cases and always associated with lead.

Analyses of the tapes by acid digestion and atomic absorption spectrophotometry gave zinc/lead/cadmium ratios similar to those found in vegetation1 or moss bags2. The larger size of the lead-containing particles accounts for the much greater number of zinc particles, since the absolute amounts of the two metals is in the approximate ratio of 2 of zinc to 1 of lead.

Only a small number of the total number of particles trapped have been examined so far; hence conclusions must be tentative. Also the particles examined may not be truly representative of all fallout particles from the complex.

But these results seem to suggest the presence of zinc in • two forms: (1) in the presence of silicon, presumably as a form of silicate, and (2) in the presence of sulphur, either as sulphide or sulphate. As the Kevex detector will not respond to elements. below atomic number 11 we cannot at this stage distinguis between a sulphide and sulphate.

As lead was found in the presence of varying amoun' zinc and cadmium but not with silicon or sulphur, it m present as some form of oxide. Cadmium has been foun

rarely and always in the presence of lead and at much lower levels.

Unfortunately, since our method is only qualitative, the relative ratios of the elements in different particles cannot be determined. Using ESCA techniques it may be possible to determine the oxidation state of the elements such as zinc, lead and sulphur within the particles. This would then offer a more meaningful indication of the exact chemical composition of the fallout. This work is now in progress.

# Residence time of sphere or air bubble in sheared non-Newtonian fluids

During experiments to measure the residence time of air bubbles in a stirred beaker, we observed that for polyacrylamide solutions the bubbles rose more slowly as rotational speed was increased (Fig. 1). This result contradicted our expectation that 'shear thinning' of a non-Newtonian fluid would result in a more rapid rise of the bubbles. The multiple-rod impeller used in these initial experiments was similar in design to that used by Steel and Maxon¹ for aeration of a novobiocin-producing actinomycete. Single air bubbles of known volume were generated by a Chromatronix 4-way valve; bubble size could be changed by changing the size or length of the splitting loop on the valve, and the volume of the bubble was checked by measuring its length in a capillary tube of known cross-sectional area. The rise of air bubbles was traced by high speed film.

This unexpected phenomenon was further investigated in a modified Couette viscosimeter device. The bob, 3.85 cm in diameter, was driven by a variable-speed motor while the cup, 11.20 cm in diameter, was stationary. The height of solution in

Table 1 Residence time as a function of radial distance for falling

the annular space was 21 cm. Because there was distortion of 4% and 12% on the bubble's minor and major axes as the multiple-rod impeller swept past the bubbles, rigid aluminium spheres were also used to eliminate the possibility that deformation of the bubble was a cause of the observed effect. Residence time per unit height was found by observing the time of rise or fall for six to ten repeated runs through a fixed distance of 10 cm. The relative residence time,  $\theta_{\rm r}$ , is the ratio of the residence time in a sheared solution to that in a stagnant solution. Two pseudoplastic polymer solutions were investigated: 0.6% aqueous polyacrylamide (Polyhall 295) and 1.0% aqueous polyethylene oxide (Polyox WSR-301).

When air bubbles were released at the same radial position, the relative residence time increased with increasing shear rate and eventually reached an asymptotic value for both Polyhall 295 and Polyox solutions (Figs 2 and 3). Control tests with glycerol, a Newtonian liquid, showed that  $\theta_r$  was independent of the shear rate, as it should be. These observations confirmed what had been found for the multiple-rod stirrer. On the other hand, for falling rigid spheres in the Couette device a maximum in  $\theta_r$  was noted. For small spheres at sufficiently high speeds of the bob a shear-thinning effect did occur, but at lower speeds and for larger spheres there was again an abnormally high residence time.

It is difficult to account for this behaviour. Secondary flows can occur in the annulus of a Couette device (Taylor instability), especially when the inner rather than the outer cylinder is

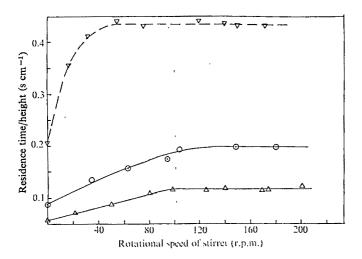

Fig.1 Residence time per unit height for air bubbles in Polyhall 295 solutions stirred by multiple-rod stirrers. The concentration of Polyhall solutions were:  $\triangle$ , 0.2%;  $\odot$ , 0.3%;  $\nabla$ , 0.5%. Air bubble diameter was 5.12 $\pm$ 0.02 mm, and the temperature of the solution was 22.5 $\pm$ 0.5° C. Bubbles were released at the mid point between the shaft and the wall.

rotated<sup>2</sup>. No such secondary flow was expected or was observed at the shearing rates used here, however, an end effect at the bottom was observed in the Polyhall 295 solution, but the torus-shaped circulation never extended above 6 cm from the bottom. The end effect did not influence the results because the timed distance for the fall of the spheres was always above this level. The anomalous shear 'thickening' effect may result from the asymmetrical flow field around a rising bubble or falling sphere; the normal stress distribution may be such as to create a net opposing elastic force. As the particle diameter increases, deviation from the ideal flow field becomes more prominent and the normal stress effect is more noticeable.

A further observation which confirms the increase in apparent transverse viscosity with increasing rate of shear is summarised

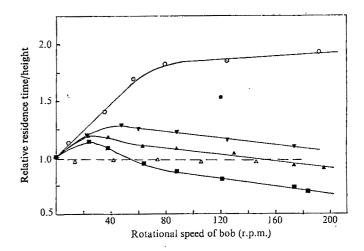

Fig. 2 Relative residence time per unit height in 0.6% Polyhall solution. ⊕, Rising air bubble in 0.6% Polyhall; △, in glycerol (0.452 N s<sup>-1</sup> m<sup>-2</sup> (452 cpoise at 22.5° C). Both at 22.5±0.2° C. Air bubble diameter was 5.13±0.02 mm. Aluminium spheres with diameters: ■, 1.59 mm; ▲,3.17 mm; ▼,4.76 mm, were released at the same radial distance from centre (r = 3.3 cm) at 25.2±0.2° C. Dashed line, Newtonian behaviour.

in Table 1. For a given size of sphere and angular velocity of the bob, the residence time increased as the radial distance between the point of release of the sphere and the bob decreased. The highest shearing rate is next to the rotating bob and, therefore, the residence time should have decreased in the vicinity of the bob if the polymer had a shear thinning property when the sphere was travelling transverse to the shear field. In qualitative terms, the chains of polymer molecules can be visualised as more uniformly aligned near the rotating bob than distant from it. Thus, a falling sphere penetrates the random molecular array at some distance from the bob faster than it penetrates the oriented or 'structured' molecules close to the rotating bob.

Highgate and Whorlow<sup>3</sup> found only slightly anomalous behaviour in a sphere falling through a sheared solution of 10% polyisobutylene in tetralin, another non-Newtonian system. They observed a decrease in 'transverse viscosity' as the shear

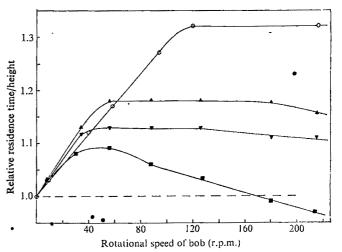

Fig. 3 Relative residence time per unit height in 1.0% Polyox WSR-301 solution.  $\odot$ , Rising air bubble with diameter  $5.13\pm0.02$  mm at  $24.7\pm0.2^{\circ}$  C. Aluminium spheres with diameters:  $\blacksquare$  1.59 mm;  $\blacksquare$ , 2.50 mm;  $\blacksquare$ , 3.17 mm, were released at the saradial distance from the centre (r=3.3 cm) at  $24.5\pm0.2^{\circ}$  Dashed line, Newtonian behaviour.

rate was increased, but the thinning effect was not as large as would be predicted from conventional measurements assuming that viscosity is an isotropic property. Perhaps still other systems and geometries need to be tested to ensure that the effect is not an artefact and to explore its dependence on the molecular properties that give rise to non-Newtonian behaviour.

We thank Dr James F. Stevenson for stimulating discussion.

### Polymeric film precursors in the homogeneous crystallisation of some metal oxides

WE have already reported1,2 the occurrence of two-dimensional polymeric structures prior to precipitation in the system ZrOCl<sub>2</sub> (aqueous solution) -> ZrO<sub>2</sub> (monoclinic). Here we show that similar thin polymeric films are precursors in the precipitation of αFeOOH, βFeOOH, and V<sub>2</sub>O<sub>5</sub>.H<sub>2</sub>O, and that the morphology

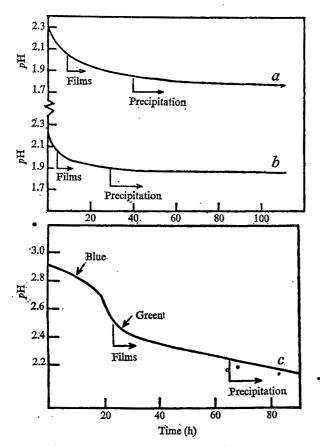

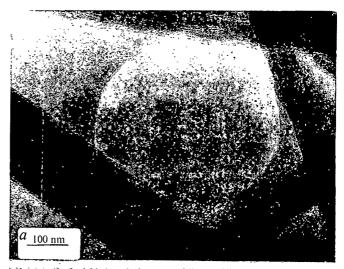

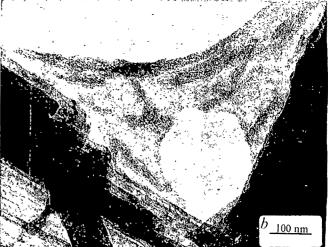

Fig. 1 Dependence of pH on time for the hydrothermal precipitation of a, a FeOOH, b, B FeOOH, c, V<sub>2</sub>O<sub>5</sub>.H<sub>2</sub>O hydrolysis at 313 K.

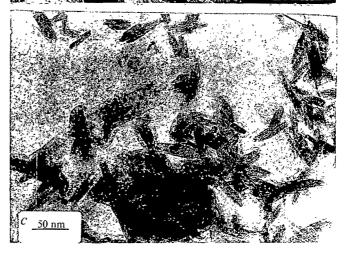

Fig. 2 a, Thin film suspended between asbestos fibres, sample taken at an early stage of film formation from FeCl<sub>3</sub>, the solution being optically clear. b, Film from FeCl<sub>3</sub> just before precipitation. The pod-like βFeOOH crystals are forming on the film the area of which is diminished as the crystals grow. c, Final precipitated product from FeCl<sub>3</sub> solution—βFeOOH.

and nature of these precipitates arises from the manner of condensation of these films to form a crystalline precipitate.

High resolution electron microscope examinations have been carried out on the aqueous systems FeCl<sub>3</sub>→βFeOOH Fe(NO<sub>3</sub>)<sub>3</sub> →αFeOOH, and VOSO<sub>4</sub>→V<sub>2</sub>O<sub>5</sub>.H<sub>2</sub>O. Also the morphology of the oxide precipitates from a range of metal oxides has been surveyed. In all cases the concentration of the solution was 0.01 M and the solution was allowed to stand at, or above, room temperature until precipitation occurred. Samples of the hydrolysis solutions were removed at intervals for electron microscopy and pH measurements. To obtain background-free micrographs and to detect film formation the aqueous samples were sprayed on to a mesh of asbestos fibres supported on an electron microscope specimen grid<sup>1</sup>.

Initially in the Fe(NO<sub>3</sub>)<sub>3</sub>, FeCl<sub>3</sub>, and VOSO<sub>4</sub> systems there was a marked fall in pH, although at this stage the samples gave no detectable deposit on the asbestos mesh. As the drop in pH diminished, examination by electron microscopy of the samples revealed thin films suspended between the asbestos fibres. The bulk solution remained optically clear during this entire period. We may conclude that the hydrolysis process was largely complete when such films had been formed in solution, since the majority of the theoretically possible fall in pH had taken place. The process of crystallisation had not begun, however, since these films showed no regular structure, nor gave rise to diffraction.

In later samples the film was observed to thicken, in some cases unevenly with regions exhibiting periodic lattice striations. This sequence of events is the same as was observed in the  $ZrOCl_2 \rightarrow ZrO_2$  system.

Figure 1 shows the pH/time dependence of the various solutions with the formation of films and precipitates indicated. Figure 2a and b show the films from the FeCl<sub>3</sub> solution with podlike structures developing in the film whilst Fig. 2c shows the

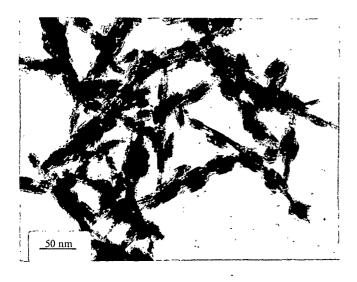

Fig. 3 The final precipitate from a FeCl<sub>3</sub>/Fe(NO<sub>3</sub>)<sub>8</sub> mixture with a Cl<sup>-</sup>/NO<sub>3</sub><sup>-</sup> ratio of 0.2. The crystals had the structure of  $\alpha$ FeOOH but are of similar morphology to  $\beta$ FeOOH, as in Fig. 2c.

final precipitated product— $\beta$ FeOOH. The VOSO<sub>4</sub> and Fe(NO<sub>3</sub>)<sub>3</sub> systems showed even film thickening and ultimately lath-shaped crystals of V<sub>2</sub>O<sub>5</sub>. H<sub>2</sub>O and  $\alpha$ FeOOH were precipitated. Similar lath-shaped crystals were observed as the final precipitates for the systems: SnCl<sub>2</sub>, SnCl<sub>4</sub> and AlCl<sub>3</sub>. NbCl<sub>5</sub> and TiCl<sub>4</sub> gave an irregular crystal and small cubic crystal respectively but in both cases hydrolysis and precipitation occurred immediately the salt was dissolved in water. To investigate the effect of the anion, mixtures of Cl<sup>-</sup> and NO<sub>3</sub><sup>-</sup> in the Fe<sup>3+</sup> solutions were hydrolysed, and these gave precipitates of the crystal structure of  $\alpha$ FeOOH for anion ratios 0–50% Cl<sup>-</sup>/NO<sub>3</sub><sup>-</sup> but the precipitate

had the pod-like shape of βFeOOH (Fig. 3). Greater Cl<sup>-</sup> proportions gave pure βFeOOH crystals and no mixtures of crystal products were observed. During crystal formation there was very little drop in pH. The similarity in appearance between the thin films of polymeric species produced in both the Fe(NO<sub>3</sub>)<sub>3</sub> and the FeCl<sub>3</sub> systems indicate that the final crystalline product is determined by the manner in which the anionic counter ion affects the film thickening process.

In these solutions both the Cl<sup>-</sup> and  $NO_3$ <sup>-</sup> are present in 0.03 M compared to an OH<sup>-</sup> concentration of  $10^{-11}$  M initially. The Cl<sup>-</sup> is a stronger complexing agent than  $NO_3$ <sup>-</sup> (ref. 4) but present in a much greater concentration than OH<sup>-</sup>, therefore, it is reasonable that the thin film would be stabilised as a two-dimensional entity by the presence of Cl<sup>-</sup> ions, in both of the axial positions of the octahedral Fe<sup>3+</sup> ions, to a greater extent than when  $NO_3$ <sup>-</sup> is a counterion.

The tendency for multilayer formation in the NO<sub>3</sub><sup>-</sup> system is, therefore, much greater, accounting for the more general thickening of the films, whilst in the Cl<sup>-</sup> system the film is more likely to crystallise by a rolling up or self condensation mechanism. The nature of the anion and its concentration, is therefore critical to these systems and a strong ligand will suppress or even stop the hydrolysis process.

These results lead to more general conclusions about precipitation mechanisms in metal oxide systems. The first stage is the hydrolysis of the metal ion which then polymerises by way of hydroxide bridges<sup>4</sup> into a two-dimensional film, with a release of hydrogen ions. The crystal formation and precipitation follows this stage with crystal growth being controlled by the anion present, which determines the manner in which the films assume a three-dimensional structure. This growth stage represents the elimination of water from hydroxide bridges to give an oxide structure. These stages may be generally represented as:

$$p[(MH_2O)_x]^{n+} \frac{\text{rapid}}{pH \text{ drop}} [M(OH)_y(H_2O)_{x-y}]_p^{p(n-y)+} + pyH^+$$
Thin film
$$Dehydration$$

$$pMO_{n/2} + (p/2)(2x-n)H_2O + pnH^+$$

where x is the coordination number of the metal ion  $M^{n+}$ , y has values  $0 \rightarrow x$ , and p is the number of molecules involved.

The OH<sup>-</sup> may be replaced by another anion which will be eliminated during the oxide lattice formation, or only partial oxide formation may occur giving rise to oxide hydroxide compounds. The pure oxide can normally be obtained by dehydration.

The pH of the solution drops to approximately 2 at the onset of film formation which would correspond to one hydrogen ion per Fe³+. Since four equatorial OH groups would, themselves, be shared between four Fe³+ ions this agrees with a monomolecular film formation in solution. The final pH of the solution depends upon the acid retention by the final oxide product. These oxides and oxide hydroxides all have a significant ion exchange capacity, and in acid solution there will be surface groups according to the equilibrium:

• 
$$M-O_2H+X^-+H_2O = MOH+H_3O^++X^-$$

It is only after prolonged washing that the anion-free precipitate is obtained. For  $\beta$ FeOOH the ion exchange capacity is 0.52 mM g<sup>-1</sup> at pH 1.35 indicating approximately one exchange able site for twenty iron atoms. This would only be possible fo very porous solid, and the regular nature of the pore struchas been reported by Gallacher<sup>5</sup>.

This uniform porosity could be obtained by the rolling up of the thin polymeric films. It is clear that crystallisation does not occur by single atom or molecule addition in any of these systems. The nature of the anion's 'complexing' ability to the metal ion relative to that of water (or OH) will determine whether a layer superimposition occurs, as in a FeOOH, or a rolling-up condensation takes place, as in βFeOOH and ZrO<sub>2</sub>, giving rise to a regular porosity.

### New early Miocene vertebrate locality near Lake Rudolf, Kenya

For the past five years, Plio-Pleistocene sediments cropping out near the north-eastern shore of Lake Rudolf have been under investigation. The lacustrine and fluviatile sediments, which extend about 30 km east of the present margin of Lake Rudolf, have yielded a wealth of Plio-Pleistocene palaeontological and archaeological specimens. Provisional accounts of the geology<sup>1,2</sup>, chronostratigraphy<sup>3,4</sup>, archaeology<sup>5,6</sup>, hominids<sup>7-11</sup>, and vertebrate fossils12 have already been published.

During the summer of 1973, outcrops of Miocene sediments were discovered to the east of the Plio-Pleistocene Lake Rudolf Basin. The Miocene sediments are capped, and in many places covered, by younger igneous rocks that crop out over large portions of the region between Lakes Rudolf and Stephanie. The Plio-Pleistocene sediments are banked against the igneous rocks. Exposure of the Miocene sedimentary sequence seems on present evidence to be limited to a discontinuous belt surrounding the Suregai-Assille basalt plateau. Vertebrate fossils from this sequence were originally discovered during field investigation of the plateau basalts. Several vertebrate sites have been subsequently found on the flank of the plateau around 36° 36'E and 4° 16'N (Fig. 1).

In that region the sediments and associated volcanic rocks are folded into a series of small anticlines and synclines that trend in a NNW-SSE direction. The thickness of the sedimentary sequence is variable but at the vertebrate-bearing localities is about 50 m. There, the sediments lie on top of a deeply weathered and eroded basalt and are in turn capped by a later basalt flow. Potassium-argon age determination of the later basalt has given a date of 17.3  $\pm$  1.4 Myr (ref. 13).

The lower portion of the sedimentary sequence (Fig. 2) comprises a homogeneous and structureless red-brown clay, probably of lacustrine origin. Regression of the lake and its replacement by fluviatile and flood plain environments accounted for the subsequent superposition of a coarse silt sequence intercalated with sandstones, clays and fine silts. The most prolific vertebrate-bearing site occurred in a silt bed rich in root casts, algal structures and burrows. The bed is of limited lateral extent, seems to have accumulated in a shallow or

intermittent aquatic environment, and may best be interpreted as an interdistributary or behind-shore lagoonal facies. The upper part of the sequence was dominated by the influx of fine pyroclastic material now preserved as light coloured, reworked and crossbedded tuffs.

The fossils occur in small pockets within the coarse silt unit over a region of at least 2-3 square miles. Most of the specimens which weather out comprise rhinocerotid or proboscidean postcranial elements. The provisional faunal list is: Platybelodon kisumuensis, Prodeinotherium hobleyi, Megalohyrax championi, Dicerorhinus sp., Listriodon sp. Creodonta gen. and sp. indeterminate, Crocodylidae gen. and sp. indeterminate, Chelonia gen. and sp. indeterminate.

The presence of medium to small mammals is indicated by enamel and bone fragments which clearly do not belong to the taxa given in the faunal list. As yet, only a small part of the potentially fossiliferous sequence has received even cursory attention. All four identifiable taxa are typical of the early Miocene elsewhere in East Africa and an early Miocene age is confirmed by the radiometric date.

The fauna is not confined to the middle portion of the sequence, for Prodeinotherium hobleyi teeth have been collected subsequently from immediately above the basal basalt near the waterhole of Buluk (R. J. G. Savage, personal communication). Prodeinotherium teeth have also been found subsequently farther south near the village of Loyengalani where they were associated with a skull and mandible of Platybelodon kisumuensis (R. E. Leakey, personal communication). The strati-

# **Evolutionary Biology** Volume 7

edited by Theodosius Dobzhansky, Max K. Hecht, and William C. Steere

Based on the premise that evolution represents a unifying principle in the life sciences, this brilliant and widely-acclaimed series offers critical reviews, commentaries, and original papers by leading experts from a variety of biological disciplines. Volume 7 covers such vital topics as the paleobiology of the Precambrian, biochemical parameters of fungal phylogenetics, potential and actual gene flow in plants, and politics and evolutionary process. Volumes 1-6 were formerly published by Appleton-Century-Crofts.

### **Fossil and Living Dinoflagellates**

William A. S. Sarjeant

December 1974, x+182 pp., £5.00/\$13.00.

0.12.619150.6

The result is a work which, for the first time, provides a comprehensive review of available information on fossil dinoflagellates, and which discusses all aspects of the biology of living dinoflagellates likely to be of direct or indirect relevance to the understanding of fossil forms. It will be enthusiastically received by universities and colleges and in particular by commercial companies especially within the oil industry. Individual palynologists, biologists and geoloists as well as organisations engaged in marine research or geological surveys will also find this book to be of great value.

Proceedings of the Serono Foundation Symposium No. 3

### **Platelet Aggregation and Drugs**

edited by Luciano Caprino and Ennio C. Rossi

December 1974, xii+298 pp., £5.80/\$15.25. 0.12.158950.1

Platelets may play a major role in occlusive vascular disease, and for this reason the control of platelet function by means of inhibitors of platelet aggregation may substantially decrease the morbidity and mortality associated with these conditions. In this book there are chapters by leading investigators on the physiology and chemistry of platelet aggregation, the pharmacology of platelet aggregation inhibition and data on newly discovered inhibitors, the newer methodologic approaches to the study of platelet function, and the relationship of platelet aggregation to clinical states such as arteriosclerosis, hypertension and diabetes mellitus.

### **Human Intestinal Flora**

B. S. Drasar and M. J. Hill

December 1974, xii+264 pp., £6.50/\$16.75.

0.12.221750.0

The first section of the book provides a discussion of the remarkable progress made in the last fifteen years in our knowledge of intestinal flora in health end disease. In the second section the enormous subject of biochemical activities is tackled, and the final section brings the flora and their metabolism together in the examination of some selected disease states. This unique work in a fast-growing field will be of great value to gastroenterologists, biochemists and bacteriologists, and may also be of much use to pharmacologists and toxicologists.

### **Foundations of Quantum Dynamics**

S. M. Blinder

December 1974, x+226 pp., £6.50/\$17.25.

0.12.106050.0

In this monograph, Professor Blinder examines the mathematical formalism of nonrelativistic quantum dynamics. He describes the structure and foundations of this formalism in detail, emphasizing fundamental principles rather than concrete applications, but still slanting his approach towards application in the areas of molecular physics and quantum chemistry. The work should prove extremely useful as an intermediate text to span the gap between elementary wave mechanics and more advanced techniques. It will appeal to postgraduate students and advanced under-graduates in physics and chemistry, and to research workers involved with chemistry, molecular physics, spectroscopy and molecular structure.

### **Tissue Culture and Plant Science 1974**

Proceedings of the Third International Congress of Plant Tissue and Cell Culture held at the University of Leicester, Leicester, England, 21st-26th July, 1974

edited by H. E. Street

December 1974, xii+502 pp., £7.50/\$19.75.

0.12.673350.3

In this volume, reviews by nineteen international experts cover the full range of this recent work, each review introducing a particular field of study in which plant tissue and cell culture techniques have proved of key importance. They indicate the most active areas of current research and also the barriers to immediate progress, whether these lie with the need for better experimental systems or for advances in the techniques of culture.

### Aberrations of the Symmetrical Optical System

W. T. Welford

December 1974, x+240 pp., £7.60/\$20.00.

0.12.742050.9

This book provides a systematic development of geometrical optics and the optical aberration theory needed for optical design. The author provides only that material which is useful to designers with access to computers. Methods designed for outmoded computational techniques and those simply not well adapted for practical design purposes have been ignored, and the author has emphasised finite methods. This is one of the first books on aberration theory which is aimed mainly at working optical designers, and while intended primarily as a reference work, it contains some material which has previously only been published in research journals.

### The Psychology of Animal Learning

N. J. Mackintosh

December 1974, xiv+730 pp., £8.00/\$18.50.

0.12.464650.6

This book provides a comprehensive and detailed treatment of the procedures, results and interpretation of psychological studies of learning in animals, covering the original and the most up-to-date experiments and theories. There are chapters on all the major topics in the field and over 2,000 references are given.

Contents:

Introduction. Classical conditioning: basic operations. Classical conditioning: theoretical analysis. Instrumental learning: basic operations. Analysis of appetitive instrumental learning. Instrumental learning: avoidance and punishment. Contrast effects. Extinction. Generalization. Discrimination. References and author index. Subject index.

### **Natural History Photography**

edited by D. M. Turner Ettlinger

December 1974, xxxviii+396 pp., (9" ×7", 64 plates) £8.80/\$23.25. 0.12.703950.3

Natural History Photography discusses photographic techniques for a wide range of subjects, from big game to insects, caves and plants, and will be of the greatest interest to all photographers, whether professional or amateur, as well as to biologists and naturalists who wish to use photography as a means of recording their subjects.

Many of the techniques described in this book have not received much attention in previous literature and so will be of particular interest; these include very high speed-flash, stereo-photography, the use of play-back tape and cave photography.

London Mathematical Society Monographs No. 4 Series Editors: P. M. Cohn and G. E. H. Reuter

### Sieve Methods

H. Halberstam and H. E. Richert

December 1974, xiv+364 pp., £9.80/\$26.00.

0.12.318250.6

This, the first book to be devoted to sieve methods, breaks new ground by describing clearly and in detail an area which has tended to be up to now the preserve of a handful of experts.

Contents:

Introduction. The sieve of Eratosthenes: formulation of the general sieve problem. The combinatorial sieve. The simplest Selberg upper bound method. The Selberg upper bound method (continued): O-results. The Selberg upper bound method: explicit estimates. An extension of Selberg's upper bound method. Selberg's sieve method (continued): a first lower bound. The linear sieve. A weighted sieve: the linear case. Weighted sieves: the general case. Chen's theorem. Bibliography. References.

### The Cell In Medical Science

edited by Felix Beck and John B. Lloyd

December 1974, xviii+598 pp., £11.30/\$29.25.

0.12.084202.5

Contents:

Cellular Genetics and Development: Biochemical genetics. General mammalian cytogenetics. An introduction to human cytogenetics. Sex chromatin. The kinetics of cell production. Cell differentiation. Cell growth and morphogenesis. Ageing.

growth and morphogenesis. Ageing.

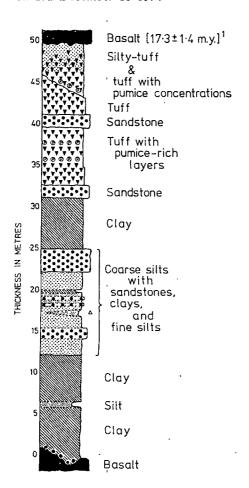

Fig. 2 Stratigraphical section at new early Miocene locality. △, Position of main vertebrate localities.

graphical relationship between the latter region and the Suregai-Assille plateau is not yet clear.

A currently more prolific early Miocene fauna has been recorded from sites of more limited lateral extent on the western side of Lake Rudolf<sup>14,15</sup>. The areal extent of the new localities on the eastern side of the lake awaits determination but is likely to prove larger than any East African site known to yield early Miocene vertebrate fossils. The new localities extend the northern limit of sub-Saharan Miocene faunas from the East African Rift System and provide complementary potential to the East Rudolf Plio-Pleistocene sediments for providing evidence of hominid origins and early evolution.

Field work was supported by grants from the Natural Environment Research Council, the National Science Foundation and the National Geographic Society. The Museum Trustees of Kenya made the fossil specimens available for study.

### Discrimination in the assimilation of *n*-alkanes in fish

VERY large quantities of hydrocarbons have been and continue to be introduced into the seas and oceans by the various activities of man<sup>1,2</sup> but estimates of this input and comparisons with biogenically-derived material or seepage from fossil hydrocarbon deposits are difficult to make. An assessment of the general effects of non-biogenic hydrocarbons on the marine ecosystem is equally difficult.

In the analyses<sup>3</sup> we have carried out on flesh and livers from wild codling caught round the coast of the British Isles the n-alkane patterns observed fell into two general types (Fig. 1). The flesh patterns had a relatively smooth profile with a minimum around hexadecane (C16), a maximum at C26-C28 and no marked odd carbon atom predominance. The liver patterns, however, showed a marked odd carbon atom predominance, a maximum at C29-C31 and, as in the flesh, a minimum in the C16 region. These profiles bear little or no resemblance to the various alkane patterns of crude oils or indeed to most hydrocarbon products. Superficially, this suggests that the alkanes were not derived from the non-biogenic hydrocarbon input to the marine environment, but our laboratory-based studies with cod (Gadus morhua) suggest that this is not necessarily the case.

Cod liver oil capsules (containing 49 mg liver oil and 1 mg topped Kuwait crude oil) disguised in the normal squid diet were fed to codling (weight approximately 500 g) at a concentration of 1 mg crude oil d<sup>-1</sup> for 175 d. The same diet without the crude oil was fed concurrently to a control group. During the subsequent 109 d period the capsules were withdrawn from the diet. The n-alkanes content and pattern in the livers after 6 months feeding with oil showed remarkable changes (Fig. 2) in that the profile of the livers of the crude oil-fed fish lost the odd carbon atom alkane predominance and assumed a profile similar to that of the flesh (Fig. 1). The relative changes in the amount of n-alkanes are given in Table 1.

Figure 3 shows a discriminatory uptake of alkanes by the liver. Thus, the alkanes around C16 do not seem to be retained to any great extent, but as the chain length increases to about C26 the relative amount retained rises to a maximum. It is not possible to state from the results of this experiment whether these differences in the retention of the n-alkanes were due to a discriminatory absorption mechanism by the liver and/or the digestive system, and/or a preferential metabolism and/or excretion of the

Table 1 Relative changes in the amount of *n*-alkanes

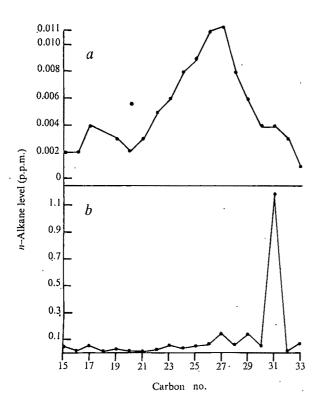

Fig. 1 Distribution of *n*-alkanes in wild codling flesh (a) and liver (b).

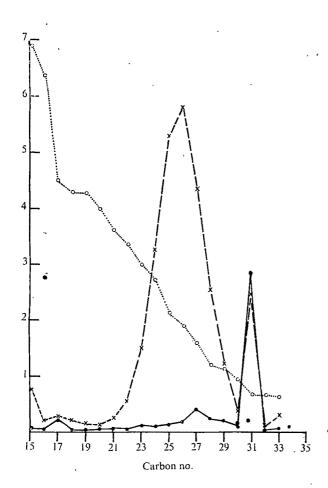

Fig. 2 Distribution of *n*-alkanes. ×, livers from codling fed crude oil for 6 months; ●, control livers (both in p.p.m.) and, ○, the crude oil used in the experiment (in µg alkanes per 100 mg crude oil). The liver results are from a mean of three fish.

shorter chain hydrocarbons. After the 6-month period following cessation of crude oil feeding, the alkanes in the liver had fallen considerably (Table 1) but the residual *n*-alkane fraction retained essentially the same oil-induced profile.

Additional experiments carried out by feeding cod with single doses of 2 µCi 1-14C hexadecane (disguised in the normal squid diet) showed that only 0.4% of the activity was recovered from the liver. Analysis of the active material by thin layer chromatography showed that it was entirely unchanged hexadecane. This seems to rule out a high metabolic conversion of hexadecane in the liver and lends some support to the presence of a mechanism in cod which discriminates between the uptake of individual *n*-alkanes in the chain length range C15-C33. This has obvious implications in considering the assimilation of hydrocarbons whether of recent biogenic or fossil fuel origin and particularly so if conclusions are drawn for the alkanes as a whole on the basis of experiments with a specific compound.

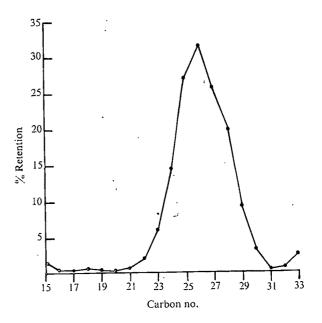

Fig. 3 Percentage retention of *n*-alkanes by the codling liver after 6 months feeding with oil as a function of carbon number.

In the cod, the liver is probably the centre of lipid metabolism and may well exercise some function of control in the deposition of alkanes in the tissues even though there is such a striking difference between the profiles of liver and flesh in normal fish. The apparent discrimination indicated by the liver analyses in the presence of a specific alkane array in the diet demonstrates clearly that, in this species, it is unlikely that a simple comparison of tissue analyses with those of the extraneous hydrocarbon source will suffice to identify the source of the tissue alkanes.

# Possible model reactions for the nitrate reductases

NITRATE is the major source of nitrogen for most green plants and fungi and may also be used by certain microorganisms as a terminal electron acceptor in place of oxygen under anaerobic conditions. The enzymes responsible for the first step in nitrate assimilation and for nitrate respiration are the nitrate reductases, both these processes involving the conversion of nitrate to nitrite. The nitrate reductases require molybdenum both for their formation and activity<sup>1,2</sup>. Chemical tests have indicated that during the enzymatic reduction of nitrate to nitrite, the oxidation state change undergone by the molybdenum present in the enzyme from Neurospora crassa involves Mo(V) and Mo(VI)3 and ESR spectroscopic studies have strongly suggested that the nitrate is directly bound to the Mo(V) centre of the enzyme from Micrococcus denitrificans before reduction'. Therefore we have investigated whether simple molybdenum(V) complexes are able to reduce nitrate to nitrite. This has been attempted previously and either no reduction of nitrate was detected3.5 or reduction occurred to yield nitric oxide as the major product. Similarly, molybdenum-catalysed reductions of nitrate have produced at the most only traces of nitrite<sup>7-9</sup>.

We report here that oxo-molybdenum(V) complexes such as [MoOCl₃L₂], [MoOCl₄L]⁻ (where L=Ph₃PO or (Me₂N)₃PO) or [MoOCl₅]²⁻ in dichloromethane solution at room temperature, will rapidly and quantitatively convert nitrate to nitrogen(IV) oxide and slowly and quantitatively reduce nitrogen(IV) oxide to nitrogen(III), probably as NO⁺. The mechanism of the reaction between an excess (≥6:1) of Et₄NNO₃ and [MoOCl₃(OPPh₃)₂] under the above conditions has been investigated using stopped-flow kinetic techniques. The results obtained are consistent with the following mechanism:

CI 
$$Ph_3PO$$
  $Ph_3PO$   $Ph_3PO$ 

The nitrogen(IV) oxide has been removed from a 1:1 reaction mixture under reduced pressure, collected and indentified by ultraviolet and infrared spectroscopy. The complex  $[MoO_2Cl_2(OPPh_3)_2]$  has been obtained from solutions containing nitrate and molybdenum(V)  $\leq$  2:1; for the higher nitrate ratios used in the kinetic studies, the redox reaction appears to be followed by nitrate substitution at the molybdenum(VI) centre.

The labilisation of the ligand trans to an oxo group is a

well known effect<sup>10</sup> and for [MoOCl<sub>3</sub>(OPPh<sub>3</sub>)<sub>2</sub>] this results in the formation of the five-coordinate intermediate b which possesses a site available for unidentate coordination of a nitrate group to produce c. A preference for the coordination of nitrate as a bidentate ligand has been noted <sup>1</sup> and d is apparently formed by chelation which involves the displacement of a chloride ion. The geometry of d is ideal for a rapid intramolecular electron transfer from the molybdenum(V) centre to the nitrato group (Fig. 1). The typical electronic ground state for octahedral oxomolybdenum(V) complexes seems (ref. 12 and C. D. Garner, P. Lambert, and F. E. Mabbs¹, unpublished) to be  $4d_{-y}$ ).

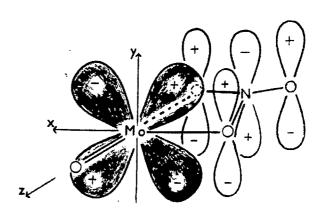

Fig. 1 Coordination of nitrate group to oxo-molybdenum (V) centre.

Nitrato complexes which contain transition metal ions in high oxidation states are powerful oxidants11 and ab initio molecular orbital calculations (I. H. Hillier, private communication) suggest that this is a result of the considerable lowering in the energy of the  $\pi^*$  orbital of the nitrate group on coordination. A rapid electron transfer from the molybdenum(V) centre to the nitrato group requires13.14 that the metal's  $4d_{xy}$  orbital overlaps to some extent with the  $\pi^*$  orbital of the nitrato group. Such overlap is only possible when the nitrato group has one and only one oxygen atom coordinated cis to the oxo group. Following the redox reaction, the electron transfer  $\pi^* \rightarrow \sigma^*$  within the nitrato group and the (slight) atomic rearrangements necessary would be expected to proceed rapidly to produce e, involving the expected10 cis- MoVIO2 unit and nitrogen(IV) oxide. As the latter has no known tendency to form complexes it is presumably readily displaced by the free triphenylphosphine oxide. At initial molybdenum(V) and nitrate concentrations of around  $1.5 \times 10^{-4}$  and  $2.5 \times 10^{-3}$ mol 1<sup>-1</sup>, respectively, this reaction sequence is completed in < 15 s at 25° C. The addition of water to the reaction mixture at this stage results in the disproportionation of the nitrogen(IV) oxide into nitrate and nitrite<sup>s 9</sup> amount of the latter being measured colorimetrically15.

The results suggest some criteria which may be important concerning the nature of the molybdenum(V) centre in the nitrate reductases. Coordination of nitrate to the metal centre could be important in lowering the activation energy for electron transfer to this group. A non-aqueous environment would favour this coordination<sup>11</sup> and therefore we suggest that the molybdenum centre of the nitrate reductases is in a hydrophobic region of the protein (which probably plays an important role in introducing the substrate to the coordination sphere of the metal). An enzymatic redox reaction between molybdenum(V) and nitrate producing molybdenum(VI) and nitrogen(IV) oxide has two main attractions: not only would the reduced species be readily displaced from the metal centre but also, once

in contact with water out of the vicinity of the metal centre, it would yield nitrite and nitrate ions, thus giving the appearance that the enzyme is actually converting nitrate to nitrite directly. The detection of nitrogen(IV) oxide in the natural systems will be difficult. ESR spectroscopy could be used, although the signal obtained from this free radical in solution can be broad and ill-defined16. The presence of an oxo group on the molybdenum(V) centre would be expected on chemical grounds10 and this group would probably dominate the reaction pathway in two respects. First, in aiding initial substrate binding trans to the oxo group<sup>17</sup> and second in controlling the electronic structure at the metal. Facile electron transfer from an oxomolybdenum(V) centre to a nitrate group will only occur if the latter is able to coordinate by way of one oxygen atom at a site cis to the oxo group with the plane of the NO<sub>3</sub> moiety containing the Mo=O axis (Fig. 1). Therefore, we suggest that, after the initial binding of the nitrate group, the enzymes must ensure that either suitable chelation or ligand rearrangement of this substrate is possible to enable one (and only one) of the oxygen atoms to be located cis to the oxo group. As there is strong evidence in favour of a molybdenum cofactor common to all the molybdenum enzymes<sup>18</sup> we suggest that the hydrophobic nature of the metal site and the facility for substrate binding cis to an oxo-molybdenum group may be important to the function of all the enzymes of this class.

We thank the SRC for financial support, Dr G. Tomalin, for the use of apparatus and Drs E. J. Hewitt and B. Notton for valuable discussions.

### Lack of effect of Avena sativa on cigarette smoking

AFTER his conclusion that an alcoholic extract of Avena sativa (the common oat) reduced craving for and consumption of cigarettes, Anand<sup>1</sup> recommended further investigation of its significance and role. We attempted the former by repeating his study in a situation less likely to prejudice participants than a chest ward and the latter by using a study design which would have cast light on the role of the treatment in altering smoking if such an effect had been evident.

The botanical state of his starting material was variously described as "selected just before harvest" and presumably yellow, and "ripe and green"2,3. Thus contents of the putative active ingredient could differ. We therefore studied both a green plant with full sized ears and a ripe plant dug up one week before the main harvesting. Ethanolic extracts of the plant including its roots were made exactly as described by Anand<sup>1</sup>. In preliminary blind studies the extract was nearly always distinguished from dummy despite the resources of a pharmaceutical laboratory. Therefore, two differently tasting liquids though approximating the musty quality of the oat infusion were prepared with an identical alcohol content. All three were coloured deep red. Subjects knew two dummies were included in varying order so they could not conclude from a change in taste that a period of test material had begun.

Employees of The Wellcome Foundation, Crewe, volunteered in response to a notice requesting help from smokers who would not object if their smoking habits altered while testing the effect of a new drug on smoking. No direct appeal was made to those anxious to stop smoking. At the end of the study a reward of 50p was offered. Smokers bought their own cigarettes.

Subjects had diary sheets and recorded their daily cigarette consumption by joining up any two dots randomly from an array of dots for each cigarette, thereby hindering a too ready comparison of their daily consumption. They also recorded the doses of extract taken each day, a subjective enjoyment rating of the day's cigarettes (better, same, less, none), any unwanted symptoms or effects as, for example, those brought on by a cold and their opinion as to whether they had received dummy or oat extract. They knew no treatment would last for less than one week and that the first would be a dummy to provide a run-in period. Diary pages were collected from the subjects separately each week and the next week's liquid issued in exchange for the used bottle. Forty-three subjects participated in the first study and eighteen of them continued into the second

Treatments were of 1 ml of appropriate ethanolic liquid diluted with 4 ml of water for palatability and taken four times daily during waking hours. They were presented as shown in

Study 1	Extrac	t immature oa	ts (EIO) v dun	nmy (D)			
week	Group 1	Group 2	Group 3	Group 4			
1	D1	D2	D2	D1			
2	D2	D1	D1	$\mathbf{D2}$			
3–6	EIO	EIO	D2	<b>D</b> 1			
7-10	D1	D2	EIO	EIO			
11–12	No treatment						
No. of	_		_				
subjects	7	14	7	15			

Volunteers had to decide whether they had taken oats or dummy infusion. Statistical analysis suggested that their decisions were guesses rather than detections of the oat preparation. Any persistent effects would have been observed in the period following the oats administration. The volunteers expected to learn at the end of the tenth week in which period

they took the test liquid. Actually all were misinformed and only correctly informed at the end of the twelfth week. If any real effect had operated by psychological rather than pharmacological means it might have diminished in volunteers of groups 3 and 4 during weeks 11 and 12.

Subjects' cigarette consumptions at a rate different from that of groups 1 and 2 during weeks 7 and 8, were compared for each week and period of the trial, allowing for different order of administration of preparations, by means of analysis of variance. The mean daily cigarette consumptions for each period in study 1 (43 subjects) were: run in (weeks 1 and 2) 23.5; EIO (weeks 3-6 or 7-10) 24.4; dummy (weeks 7-10 or 3-6) 24.0; run out (weeks 11 and 12) 25.4 (36 subjects). Individual subjects' mean daily consumption varied between 12 and 42 per day in the run in period, individual extreme consumptions being 6 and 54. Twenty-three subjects' mean daily consumptions were higher in the EIO period than the dummy period; fifteen consumed less in the EIO period and five did not change. The two largest individual changes in daily consumption between periods on EIO and dummy were respectively a rise from 21 to 27 (average 21 on run in) and a fall from 32 to 25 (26 on run in).

The study finished just before a Christmas holiday when unusual social factors affect smoking habits. The study of the mature oats was therefore postponed. As the volunteers were no longer naïve (nor could any others from the same community be expected to be) dummies were not given during the run in periods. Instead, one-half took immature oats infusion over weeks 2 to 4 while the other took mature oats and in weeks 5 to 7 each group took the alternative. No significant differences between EIO and EMO were evident. Mean daily cigarette consumptions in study 2 (18 subjects) were run in 25.6, EIO 24.7 (14 subjects) and EMO 24.9. Four subjects stopped smoking after completing the second study because the 'budget' raised the cost of cigarettes. Regretfully we conclude that the views of our compatriot, Dr Samuel Johnson, on oats would not have been modified by our study, though by its lucky timing his views on excise might have been.

### Marijuana metabolites measured by a radioimmune technique

THE recent surge of interest in the pharmacology of cannabinoids has created a need for a rapid assay for  $\Delta^9$ -tetrahydrocannabinol  $(\Delta^{0}$ -THC) and its metabolites in body fluids. A sensitive immune technique has proved elusive, and quantitation requires a multistep chromatographic and mass spectroscopic analysis<sup>1</sup>. Gas liquid chromatography with electron capture detection has also been used<sup>2,3</sup>. We describe here a simple rapid radioimmune assay for  $\Delta^9$ -THC utilising goat antiserum obtained as previously described4.

A standard antibody-binding curve was obtained as follows: 4.5 ng (5,000 c.p.m.) of <sup>3</sup>H-Δ<sup>8</sup>-THC (specific activity 465 mCimMol  $^{-1}, more than 98\,\%$  pure, New England Nuclear Corp.) was incubated for 2 h at 4° C with increasing dilutions of antiserum (0.3 ml). The latter were made up with phosphatebuffered saline (PBS), 0.1 M in phosphate, pH 7.0 in 0.1% human  $\gamma$  globulin. After this initial incubation, 1 ml of a cold

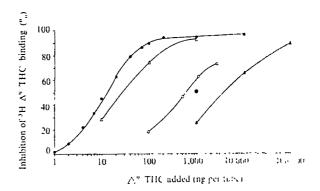

Fig. 1 Inhibition of <sup>3</sup>H-Δ<sup>9</sup>-THC binding to antibody increasing amounts of unlabelled THC metabolites. •, Δ°-THC; Δ, 11-hydroxy-Δ°-THC; Ο, 11-nor-9-carboxy-Δ°-THC; Δ, cannabidiol.

dextran charcoal suspension (0.25% dextran-2.5% activated charcoal in PBS), was added and incubation continued for 15 min. The tubes were then centrifuged at 3,000 r.p.m. for 15 min at 4° C and the supernatant (1 ml) was counted in a Nuclear Chicago liquid scintillation spectrometer (70% tritium counting efficiency) with Aquasol (New England Nuclear Corp.), as the scintillation fluid. Binding of <sup>3</sup>H-Δ<sup>8</sup>-THC by normal goat serum under the foregoing conditions was slightly above background. A maximum of 50% of marker was bound by a 1,60 early antiserum dilution. The latter serum dilution was used in the inhibition experiments described below.

To ascertain the specificity of the antiserum, various amounts of cold Δ9-THC, 11-hydroxy-Δ9-THC, 11-nor-9carboxy-Δ°-THC and cannabidiol were added to a 1/60 dilution of antiserum 30 min before addition of 4.5 ng <sup>3</sup>H-Δ<sup>6</sup>-THC. The sensitivity of the inhibition assay was 1.2 ng per tube at a 95% confidence limit. A sample inhibition experiment at 50% binding is plotted in Fig. 1 and percentage cross reactivities are tabulated in Table 1.

Table 1 Cross reactions of canna	binoids with THC antiserum
A <sup>p</sup> -THC 11-Hydroxy-THC 11-Nor-9-carboxy-THC Cannabidiol	% Cross reaction 100 47 2.6 0.5

\*At 50% inhibition

The association constant for the antiserum was determined graphically from a Scatchard plot. In the range of dilutions tested, crude antiserum bound THC at  $K_a = 4.0 \times 10^8$  M indicating a potential sensitivity of 300 pg per tube.

After a preliminary adsorption with charcoal5, samples of male plasma treated with known quantities of Δ9-THC (50-700 ng ml-1) were measured. Samples of 1 ml were shaken with heptane ethanol (100:1.5), the extracts were dried and the residue was dissolved in 0.5 ml of 50% ethanol. This solution (50 μl) was used in inhibition assays. Ideally the assays should have shown 5, 10, 20, 50 and 70 µg per tube, respectively. Their deviation from these points on the standard curve (Fig. 2) was small and within the limits of experimental error.

Plasma samples were obtained from chronic users of marijuana who were part of a controlled marijuana research project and had used no other drug for at least 10 d previously. Blood was drawn 15 min after they had smoked a marijuana cigarette (0.9 g) containing 2.1 % (18.9 mg)  $\Delta^{o}$ -THC. Plasma was separated by centrifugation and stored frozen at - 10° C. These samples (1-3 ml) were extracted with heptane-ethanol. Aliquots (0.25 ml) of reconstituted extract were used in the radioimmune assay system already described.

In each of six plasma samples  $\Delta^9$ -THC was detected and quantitated 30 min before and 15 min after THC use. Preintoxication levels were 60-100 ng ml<sup>-1</sup>. Postintoxication levels

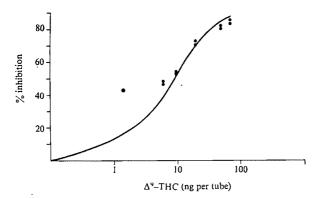

Fig. 2 Percentage inhibition of  ${}^3H-\Delta^8$ -THC-azoTHC binding by (—) various amounts of cold  $\Delta^9$ -THC added from a stock reagent vial, and (:) various amounts of cold  $\Delta^9$ -THC extracted from serum samples after treatment with  $\Delta^{0}$ -THC. Tests were done in duplicate.

were 200-250 ng ml<sup>-1</sup>. This represents 0.032% of total THC in the standardised cigarette. A significant portion of the remainder was presumed to have been exhaled. The amount of THC distributed in other body compartments is an important consideration but not of concern here.

Immunisation with Δ9-THC protein conjugates and testing of antibodies with plasma samples have been hampered by the relative insolubility and nonspecific binding of THC to serum protein. This binding can result in very high blanks and thus interfere with inhibition and assay interpretation. This was overcome in our early studies involving fluorescence by minimal fluorescence perturbation with nonspecific THC-protein binding and in recent experiments involving radioimmune methods through manipulation of the charcoal suspension.

Our antiserum was characterised by a low cross reactivity with closely related THC metabolites and other cannabinoids, the only exception being 11-hydroxy-Δ9-THC, now considered an insignificant contributor (paper presented by M. Wall at International Congress of Pharmaceutical Sciences, Sweden, 1973). The relative insolubility of 11-nor-9-carboxy- $\Delta^{0}$ -THC in the extraction solvent (heptane-ethanol) and its low cross reactivity with  $\Delta^9$ -THC makes its contribution negligible.

Although the sensitivity of our method is limited to 25-50 ng ml $^{-1}$  (4.5 ng of  $^{3}$ H- $\Delta^{8}$ -THC is required to provide 2,000 c.p.m. per sample tube), it can be used to estimate cannabinoids in chronic marijuana users. We are developing markers with much higher specific activities (100-200 Ci mmol<sup>-1</sup>) to enhance sensitivity into the pg ml<sup>-1</sup> range, for clearance studies and investigation of occasional abusers.

For body fluid determinations to be made several hours or more after exposure to marijuana, it would seem desirable to detect 11-nor-9-carboxy-THC6. Therefore we are preparing antibodies which are directed separately to the latter metabolite\*. Thus body fluid and tissue contents of each metabolite should more easily be correlated with psychoactive effects than was previously possible.

This work was supported in part by a grant from the National Institute of Mental Health Center for Studies of Narcotics and Drug Abuse.

\* Note added in proof: We now have a simple radioimmune assay specifically towards this important metabolite.

### Cortical potentials evoked by finger displacement in man

THE neuropsychophysiology underlying the sense and change of limb position in animals and man is a centre of enquiry by many disciplines ranging from medicine and physiology to psychology and sociology1. Consistent changes in the electrocorticogram (ECoG) following change of position have, however, not yet been reported in man, although recordings of unit activity during neurosurgical operations have demonstrated neuronal activity in cortex<sup>2</sup> and subcortical structures3-5. Limited data from scalp recordings after passive movement have also been reported<sup>6,7</sup>.

Electrical changes, time-locked to movement of the index finger, have now been recorded from twelve subjects using cortical and scalp electrodes. The cortical recordings have been obtained from chronically implanted subdural gold wire electrodes in seven subjects selected for treatment by multifocal leukocoagulation8,9. Simultaneous cortical and scalp recordings were taken from these patients. Scalp recordings have been obtained from five normal subjects. The position of the cortical electrodes was determined by X-ray photography and by the reversal across the central fissure of the early negative component of the somatosensoryevoked responses after contralateral median nerve stimulation10-12. Precise localisation of the electrodes was not always possible and they have been grouped in three areas: (1) postcentral, immediately posterior, and (2) precentral, immediately anterior, to the central sulcus; and (3) prefrontal, close to the tip of the frontal lobe. All electrodes were in the right hemisphere about 5 cm lateral to the saggital plane. The scalp electrodes were placed 2 cm above the nasion to monitor eye movements, at the vertex, and over the preand postcentral cortical areas of both hemispheres.

Displacement of the left or right index finger by about 45° around the metacarpophalangeal joint was by a mechanical arrangement which permitted unobstructed return of the finger to the resting position. The displacement was monitored using a movement transducer. The differentiated and grossly amplified output of this transducer was used to trigger the PDP-12 computer used for multichannel data collection of the electrical brain activity for 1 s before and 1 s after the displacement. The electromyogram (EMG) from the arm flexors and extensors were also recorded. Time constant and upper frequency response of the electroencephalogram were 1.2 s and 700 Hz, respectively.

In all subjects, cortical and scalp recordings showed consistent responses after displacement. Figure 1 shows the responses recorded from three cortical and one scalp electrode to contralateral and ipsilateral displacement. To contralateral displacement the pre- and postcentral cortical areas showed an initial positivity with a delay of 34±6 ms to peak and  $42\pm4$  ms, respectively. The amplitudes ranged from 5 to 25 µV across subjects and were usually larger in postcentral areas. This positivity was followed by a negative wave with a peak latency of  $68 \pm 15$  ms for precentral and 97±20 ms for postcentral areas, its amplitude ranging from 30 to 50  $\mu$ V across subjects. The response continued for 400 ms with a number of positive and negative components. These late components, although consistent for an individual, were variable across subjects. In the prefrontal

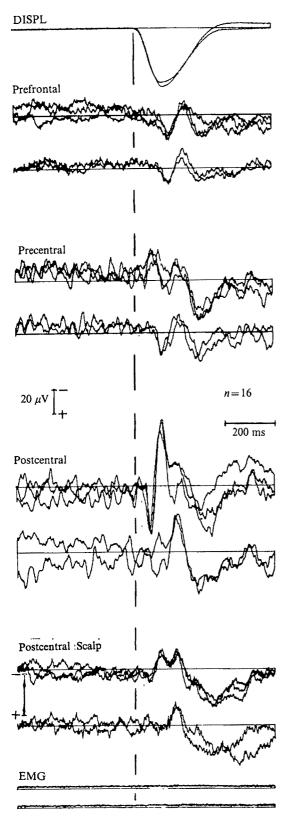

Fig. 1 Superimposed average cortical and scalp responses following externally paced left (upper trace of every pair) and right (lower trace) index finger displacement (DISPL). Interrupted vertical line shows the trigger point. Both cortical and scalp recordings from the right hemisphere with electrodes at prefrontal, precentral and postcentral cortices. The electromyogram (EMG) of the arm flexors does not change after displacement. Note the consistency in waveform for the same area under similar stimulus condition, the differences in waveform for different areas simultaneously registered and the different response of the same area, except prefrontal, to contralateral and ipsilateral displacement. Cortical electrodes referred to average of 60 electrodes in frontal lobe. Scalp electrodes referred to commoned electrodes on each mastoid process.

areas the responses to contralateral displacement started later than 100 ms and were similar to those evoked by ipsilateral movement. After ipsilateral finger movement, the pre- and postcentral areas gave different responses from those after contralateral displacement. The ipsilateral responses started with a positive deflection with a latency of 60 ms or more. Comparisons within subjects, of the total response to contralateral displacement from prefrontal, precentral and postcentral areas, showed different waveforms. Cross-correlations of responses recorded from electrodes within any one of these areas were high (about 0.85) but cross-correlations between responses from different areas were low (about 0.25).

Flexion or extension of the limb did not change the configuration or the spatial distribution of the displacementevoked potentials. This and the absence of EMG activity

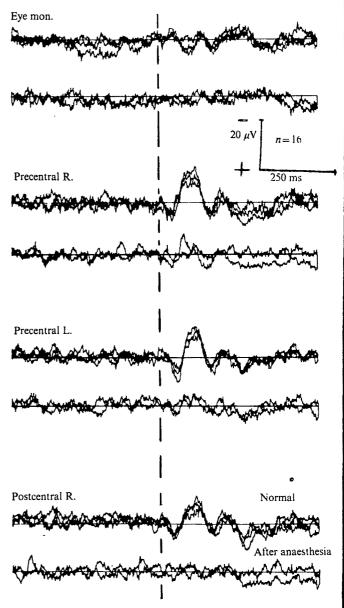

Fig. 2 Superimposed average, scalp-recorded, responses following externally paced left index finger displacement. Interrupted vertical line shows the trigger point. Eye mon., activity at an electrode 2 cm above the nasion for monitoring eye movements. Electrodes corresponding to precentral and postcentral cortical areas of the left or right hemisphere are marked L or R Upper trace of every pair, normal activity of the indicated location before, during and after displacement. Lower traces, activity of the same locations to similar displacement 45-55 min after anaesthesia of the hand with anoxia (AN). Note the loss of the responses after anaesthesia.

during the displacement indicate that muscle afferents contribute very little, if at all, to this response. To test this hypothesis anaesthesia of the joint has been imposed through ischaemic anoxia in normal volunteers, as previously described13. For 10 min the blood circulation in arm and hand was stopped by applying pressure with the cuff of a manometer just above the elbow joint. A second manometer encircled the wrist and was inflated and the pressure above the elbow relieved, thus permitting free blood circulation for the arm muscles. Scalp responses evoked between 45 and 55 min after anoxia are compared with the pre-anoxic responses in Fig. 2. The response is greatly reduced although the muscles of the arm and their sense organs are in normal conditions. We conclude that muscle afferents do not contribute to the displacement-evoked responses which most probably reflect activation of joint afferents. Activation of these afferents evokes different electrical changes in prefrontal, precentral and postcentral cortical areas. This differential representation in the cortical level of the input activated by displacement, as well as the timing of the various components of the response, offer an objective index in understanding the brain mechanisms of position sense in normal man and in patients.

### Visualisation of micropore structure in human dental enamel

Dental enamel has an internal void volume of 0.2-5%1-3. The direct observation of pores in enamel, however, has been hindered by inadequate specimen preparation techniques. The harsh chemical treatment necessary to partially demineralise enamel prior to embedding and sectioning, and the chatter and shattering effects which result from cutting hard tissues. create artefactual spaces in enamel which make it virtually impossible to identify and define any natural spaces present. Attempts to cut enamel which has not been demineralised produce even greater shatter and destruction of the natural structure.

Transmission electron micrograph of longitudinal section of ion beam thinned human dental enamel showing the long lath structure of apatite crystals with electron lucent channels or pores between them. Ion beam thinning may remove organic material faster than the mineral phase but because it is a mild process in which the incoming ions knock out individual surface atoms it does not result in any detectable gross morphological artefactual damage as produced by other ultra sectioning techniques. Human teeth extracted from young healthy adults 20 to 30 years of age were obtained from the Royal Dental Hospital of Melbourne and fixed in 10% v/v isotonic buffered formal saline for 24 h at room temperature. After washing in water and air drying, the teeth were embedded in Servic polyester resin (obtained from R. F. Service, 272 Brunswick Street, Fitzroy, Melbourne) and cured for 24 h (×180,000).

We have observed with the electron microscope a micropore structure in human dental enamel using an improved technique in which specimens are prepared by alumina jet dimpling followed by ion beam thinning4. This technique enables the preselection of a defined area for preferential thinning, making it suitable for electron transmission.

Longitudinal serial sections (300 µm thick) of resin-embedded teeth were prepared by the method of Malcolm<sup>5</sup>. After lapping by hand to approximately 100 µm thickness and after polishing both sides, the sections were mounted on glass slides using an alcohol-soluble medium, such as canada balsam. Using a light microscope, areas of enamel were selected in each specimen (a) in the vicinity of the dentino-enamel junction in the cusp region and (b) midway between the surface and the dentino-enamel junction in the central region between cusp tip and the cervix. These areas were then enclosed by cementing a slotted grid or ring to the specimen with a rapid-setting alcohol-insoluble cement. The grid or ring also provides support for the specimen. A dimple (diameter < 1 mm) was made on the area selected by accurate positioning under a jet of fine alumina directed from a fine silicon carbide nozzle. Rate of dimpling was controlled by the nitrogen gas pressure operating the jet; the use of different size jets, combined with varying

specimen-jet distances, enabled determination of the area thinned. A specimen thickness of approximately 30 µm in the dimpled area was found suitable for ion beam thinning; this was measured optically or using a dial gauge. After dimpling, the disk was separated from the glass base by immersion in alcohol and then trimmed with a sharp knife. The disk, mounted in a stainless steel holder, was tilted to approximately 15° to the plasma beam in an ion beam thinning unit. Perforation of the dimpled area (monitored microscopically) was the criteria determining suitability for electron microscopy. The exact identification in the electron microscope (JEM 200 kV) of specific features noted optically was achieved by careful photographic comparison before and after thinning. Electron diffraction was used to determine the precise orientation of enamel crystals in any one field. The transmission electron microscope observations showed that human dental enamel prepared as above had no detectable gross morphological artefactual damage found with other ultra-sectioning techniques.

In longitudinal section, enamel crystals appeared to be long lath or ribbon-like structures extending across the field without interruption, except at prism boundaries. These crystals (approximately 30-90 nm wide) appeared to be of indeterminate length with none of the cross fractures usually observed in electron micrographs of enamel crystals. The most striking feature in all areas of the enamel examined, however, was the presence of electron-lucent channels running between, and parallel to, the crystals (Figs 1 and 2). These channels or pores (1-10 nm wide; average width about 5 nm), like the crystals, appeared to be of indeterminate length in longitudinal sections; they may run for long distances through the enamel rods and

Fig. 2 Transmission electron micrograph of transverse section of ion beam thinned human dental enamel showing flattened hexagonal apatite crystals with irregularly shaped holes separating the individual crytsals. ( $\times$ 80,000)

only terminate at a rod boundary or free surface. They were best observed in slightly out of focus micrographs because of enhanced contrast due to Fresnel fringes. But the width measurements were made from in-focus micrographs. In cross section, these channels appeared as irregular shaped holes of similar diameter to that measured for the longitudinally sectioned channels. It was impossible to tell from the electron micrographs whether the channels had a material structure of their own or were merely spaces created by the packing arrangements of the crystals. The electron micrographs gave the impression that these channels were empty spaces, however, they may have contained soft material, for example organic matter, preferentially removed by the ion beam thinning.

An approximate estimate of the relative percentage volume of these pores was made by examining over 200 electron micrographs of numerous fields. The pore area and total area were calculated using a ruled grid on a transparent overlay and then multiplied by average pore diameter and crystal thickness, respectively, obtained from electron micrographs. Determination of the percentage pore volume relative to total enamel volume for a section of enamel one crystal thick gives a range from 1 to 5%, using the widest range of pore diameters.

Although this calculation is approximate, the close agreement with established figures1 is strong evidence that the pores observed here do represent the spaces in enamel, detected by indirect means.

Experimentation<sup>6-8</sup> has shown that human teeth are permeable to ions and some molecules which can pass from the pulp to the enamel surface or vice versa. The presence in the enamel of a system of pores or channels (average diameter 5 nm), which would permit the passage of ions and small molecules, would explain the permeability of this material. It must also have considerable significance for its physicochemical behaviour, particularly with regard to dissolution, remineralisation and carious destruction. These aspects are being investigated currently by a detailed quantitative analysis of the distribution and size range of these micropores in both normal and pathological enamel from cusp tip to cervix and from surface to dentino-enamel junction.

### Oral contraceptive for men

We have induced reversible infertility, with little effect on libido, in five healthy young men by giving them tablets containing methyltestosterone and ethynyloestradiol. There were no undesirable side effects and we feel that this treatment may offer a practical approach to male oral contraception.

The acceptability of oral contraceptives for women has led many people to investigate the possibility of producing similar products for use by men<sup>1</sup>. The major mechanism of action of synthetic steroid hormones in oral contraceptives is inhibition of ovulation, due to suppression of the mid-cycle surge of gonadotrophins released by the pituitary<sup>2</sup>. Oral contraceptives inhibit spermatogenesis by a similar mechanism, but so far there has been concomitant loss of libido and potency<sup>3</sup>. Clinical results<sup>4-6</sup>, however, have shown that this can be avoided if supplementary androgens are given in combination with an anti-gonadotrophic steroid such as danazol4, norgestrienone5, or ethylnorgestrienone6. But clinical testing of such combinations on a large scale cannot begin without extensive toxicological testing with animals<sup>7</sup>. We have therefore reconsidered existing oral hormone products which have been approved for sale in many countries. One group of these products<sup>8</sup> contains combinations of an androgen (usually methyltestosterone: 17α-methyl-17β-hydroxy-4-androsten-3one) with an oestrogen (usually ethynyloestradiol: 17aethynyl-1,3,5(10)-estratriene-3,17 $\beta$ -diol). They are sold for treatment of, for example, osteoporosis in men and the symptoms of 'male menopause'.

Initial studies were conducted on two men with osteoporosis who had been receiving products of this type for several months. Both proved to be aspermic, but reported no undesirable side effects, apart from a transitory nausea during the first few days. Concentrations of bilirubin, aspartate aminotransferase, alanine aminotransferase, lactate dehydrogenase, alkaline phosphatase and albumin in these men were within normal limits. With this background, we decided to test an oral androgen-oestrogen product as a contraceptive in healthy male volunteers.

The concentration of testosterone in the plasma of healthy men averages 4-12 ng ml<sup>-1</sup>, with a daily production of 5-10 mg9. Methyltestosterone has a longer biological halflife than testosterone, but a 10 mg tablet is necessary to maintain concentrations of 4-15 ng ml<sup>-1</sup> in the plasma for up to 8 h (ref. 10). We therefore used tablets containing 10 mg methyltestosterone plus 20 µg ethynyloestradiol. This combination was taken twice daily at 0800h and 1800h with meals. A recent study<sup>11</sup> suggested that this dose of oestrogen is sufficient to suppress pituitary secretion of follicle-stimulating hormone (FSH) in normal adult men. To evaluate possible side effects we compared the active hormone preparation with a placebo in the same patients. As supplies of matching placebo tablets were unavailable, the active tablets were crushed and repacked in gelatin capsules. Identical placebo capsules were packed with the same quantity of lactose. Five healthy male subjects (23-38 yr old) received daily placebo capsules for 3 weeks before taking the hormone product, but were unaware of this. The wives of the subjects all used combined-type oral contraceptives and continued to do so until advised to the contrary.

Blood and semen were collected at the start of the study and after 3, 6, 12, 18 and 24 weeks. Routine biochemical analysis of blood plasma indicated no hepatotoxicity. All semen specimens were normal at the beginning and end of the period when placebo was given, but sperm numbers and motility had decreased significantly by week 12 (that is day 63 of hormone treatment). At this time, four of the subjects were aspermic and remained so for the duration of treatment. The other subject produced an aspermic semen specimen during week 18. Semen specimens were collected at approximately monthly intervals after treatment was stopped. There was no increase in sperm in any of the men for about 15 weeks after the cessation of hormone treatment, but all then began to show a gradual restoration. Normal sperm numbers and motility were found after 35-40 weeks without treatment.

We conclude that the androgen oestrogen combination inhibited spermatogenesis, but that the effect was reversible when treatment stopped. Two subjects reported decreased libido during the initial 8 weeks (which included the placebo

period), but normal libido for the remainder of the study. Another man reported increased libido during the second half of the treatment period, while he and another subject experienced a reduction in libido after treatment was stopped.

Three subjects reported occasional mild nausea, sometimes while they were taking the placebo. No nausea was reported after week 18. There were no changes in skin, hair, breasts or micturation. When the wives of the volunteers stopped taking their oral contraceptives between weeks 18 and 34, no pregnancies occurred, as would have been expected with aspermic men.

Thus we believe that hormone preparations already being marketed for other purposes could be used as oral contraceptives for men. We recommend that these preparations be investigated further to establish the most suitable doses and administration regimen. It seems possible that similar effectiveness could be obtained with discontinuous treatment.

### LSD as an agonist of dopamine receptors in the striatum

THE mechanism of the hallucinogenic action of (+)lysergic acid diethylamide (LSD) is still obscure. Its molecular structure (containing both an indole and a phenylethylamine moiety) suggests the possibility of an interaction with brain monoamines. The earliest hypothesis postulated an antagonistic action of LSD at 5-hydroxytryptamine (5-HT) receptors in the brain1,2. More recent data rather tend to support the view that the hallucinogen mimics at least some of the effects of endogenous cerebral 5-HT3-5 Inhibition of the release of 5-HT is another suggested mechanism of action<sup>6</sup>. An interaction of LSD with dopaminergic transmission has so far not been demonstrated, although the marked attenuation of LSD-induced symptoms by chlorpromazine and other antipsychotic drugs7-8 may suggest this. Using a modification of the rotational model proposed by Ungerstedt10 we found that LSD acted as a potent agonist at dopamine receptors in the striatum.

A unilateral lesion of the nigro-striatal dopamine system of rats lowers the dopamine content in the striatum on that side. The resulting imbalance between the dopaminergic activities in the right and left striatum leads to postural and locomotor asymmetry both spontaneously and, even more markedly, in response to certain agents. Thus, drugs which enhance the release of dopamine from nerve terminals in the striatum of the intact side, for example, amphetamine, induce a rotation towards the side with the

lesion (ipsilateral circling) possibly by removing an inhibitory influence of the striatum upon the motor activity of the side of the body contralateral to the lesion. Conversely, agents like apomorphine, which stimulate dopamine receptors directly, induce rotation towards the intact side (contralateral circling), probably due to exaggerated responsiveness of the denervated striatum to these agents<sup>10</sup>.

Unilateral lesions of the nigro-striatal dopamine system were produced in male SPF rats of the stock Füllinsdorf albino by the injection into the right medial forebrain bundle (MFB) of either 3.5 µg 6-hydroxydopamine (6-OHdopamine) in 4  $\mu$ l Ringer's solution containing 0.02% ascorbic acid, or 10 µg 5,6-dihydroxytryptamine (5,6-HT) in 10  $\mu$ l of same. Using these two neurotoxic agents we obtained two groups of animals similarly depleted of telediencephalic dopamine on the side of the injection but differing in the levels of the other monoamine transmitters: 6-OH-dopamine lowered dopamine and noradrenaline levels (L.P., M.P., and W.H., in preparation), but did not alter the 5-HT content; the injection of 5,6-HT depleted dopamine and 5-HT but did not affect noradrenaline 11,12. For the measurement of drug-induced behaviour, rats were gently placed in a plexiglas box (35×20×15 cm) immediately following the intraperitoneal (i.p.) injection of the compounds. Handling alone induces in most lesioned animals a 'paradoxical' contralateral rotation10, however, which never lasts more than 3 min. The circlings during the first 5 min were therefore not recorded. The intensity of the rotational behaviour was expressed as the total number of full turns counted during 2 min at intervals of 5 min. Beginning on the 10th postoperative day, all rats were tested for their rotational responses to (+)-methamphetamine and apomorphine before LSD was given. A drug-free interval of one week was allowed between tests. As expected, the responses to (+)-methamphetamine (1-5 mg kg<sup>-1</sup> i.p.) and apomorphine (0.05-3 mg kg<sup>-1</sup> i.p.) were ipsilateral and contralateral circling, respectively. Animals treated with 6-OH-dopamine and with 5,6-HT did not differ in their responses. Ten shamoperated rats (local injection of solvent into the MFB) did not rotate in response to apomorphine and amphetamine.

LSD (tartrate) (100  $\mu$ g kg<sup>-1</sup> i.p., but not 50  $\mu$ g kg<sup>-1</sup> i.p.) induced contralateral turning, which began after 5 min and reached a peak after 15 min (Fig. 1). Doses higher than 100  $\mu$ g kg<sup>-1</sup> did not increase further the number of turns per minute but the peak of rotational behaviour was pro-

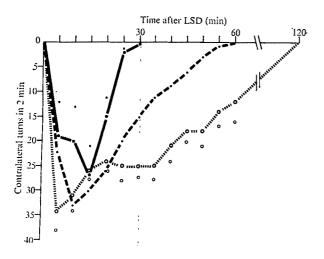

Fig. 1 Contralateral rotation (towards the unoperated side) induced by three doses of LSD injected i.p. in rats with lesions of the right medial forebrain bundle produced by the local injection of 5,6-dihydroxytryptamine. The intensity of the rotational behaviour is indicated by the number of turns in 2 min (means of ten animals per dose) s.e.m. Indicated by small points or circles. LSD doses: \_\_\_\_\_\_, 100  $\mu$ g kg<sup>-1</sup>; \_\_\_\_\_\_ 200  $\mu$ g kg<sup>-1</sup>; \_\_\_\_\_\_ 1,500  $\mu$ g kg<sup>-1</sup>.

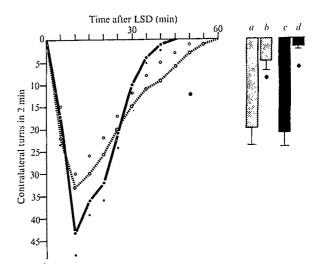

Fig. 2 Comparison of the rotational response elicited by LSD (200 μg kg<sup>-1</sup> i.p.) in rats with lesions of the right medial forebrain bundle produced by 6-hydroxydopamine (n=10) and by 5,6-dihydroxytryptamine (n=10). The right-hand side shows the effect of haloperidol (1 mg kg<sup>-1</sup>) injected 1/min after LSD. a and c, Turning activity in the two group of rats, 25 min after LSD alone; b and d, turning activity under the effect of haloperidol. Means ± s.e.m. (n=10). T difference between LSD alone and LSD+haloperidol statistically significant (P<0.01, Student's t test, two-tails Solid line and bars, 6-hydroxydopamine; dotted line stippled bars 5,6-hydroxytryptamine.

longed in a dose dependent way. The time-course o tion after LSD (100 µg kg) paralleled the temporal c of the levels of LSD in the brain13. Repeated inject LSD (200 µg kg<sup>-1</sup> i.p.) on 5 consecutive days, a s reported to induce tolerance to the hallucinogen in behaviour studies14, did not reduce the rotational re There was no significant difference between rats with 6-OH-dopamine and those lesioned with 5 the intensity and duration of contralateral circli ponse to LSD (200 µg kg<sup>-1</sup>) (Fig. 2). In both animals the injection of haloperidol (1 mg kg-1 i after the administration of LSD (200 µg kg<sup>-1</sup>) s reduced the circling behaviour (Fig. 2). Pretre before LSD, with  $\alpha$ -methyl-L-tyrosine ( $\alpha$ -MT) (' i.p.), an inhibitor of the synthesis of catecho not alter the rotational response in spite ( marked sedation. (+)-2-Bromo-lysergic acid bitartrate (BOL-148), up to 20 mg kg<sup>-1</sup> i.p., induce circling in either group of lesioned an the doses used had no detectable effect in rats.

Thus, in rats with the nigro-striatal do lesioned unilaterally by injection into the different neurotoxic agents (6-OH-dopamir LSD induced circling towards the intact side apomorphine. It seems reasonable to cor is a potent agonist at central dopamine rece depletion of noradrenaline and 5-HT in reduction of dopamine and the inhibition synthesis by a-MT had no influence on therefore, the mechanism involved in the to LSD seems to be purely dopaminergi-Haloperidol, a dopamine receptor antal effect of LSD as well as that of ap L-dopa). Further support for a dopamin action of LSD is provided firstly by its turnover of dopamine in the rat bi personal communication), secondly b weaker than that of DA, to activate cyclase in a homogenate of rat stria personal communication), and finall

cyclic adenosine 3',5'-monophosphate in rat cerebrum after its i.p. administration15. BOL-148, an analogue of LSD believed to have very weak, if any, hallucinogenic properties<sup>61</sup>, did not induce circling behaviour. In preliminary experiments, methysergide, another non-hallucinogenic lysergic acid derivative, and N,N-dimethyltryptamine, an idolealkylamine hallucinogen, were also inactive as dopamine receptor agonists. On the other hand, such an action has recently been described for some ergot alkaloids and derivates (ergocornine, 2-bromo- $\alpha$ -ergocryptine, metrine)17,18

The activation of striatal dopamine receptors is obviously not the only important central effect of LSD, since its overall behavioural effects differ considerably from those of agents believed to be fairly pure agonists of dopamine receptors. The possible importance of the dopaminergic component of the action of LSD for its hallucinogenic effect has yet to be demonstrated. It will be interesting to see whether LSD also activates dopamine receptors in brain regions other than the striatum, for example, in the limbic subsortical and cortical18,18 structures, in the hypothalamus, in the medullary chemical trigger zone, and in the retina<sup>22,23</sup>.

We thank Dr A. Kaiser of the Chemical Research Department for 6-OH-dopamine and 5,6-HT.

### LSD as an agonist and antagonist at central dopamine receptors

THE mechanisms involved in the psychotomimetic actions of D-lysergic acid diethylamide (D-LSD) and other hallucinogenic agents have not been defined. Neurophysiological and behavioural studies indicate that p-LSD may interact with serotonin and catecholamine receptors in the central nervous system. Thus, this drug seems to stimulate certain central serotonergic pathways<sup>1,2</sup>, while inhibiting the activation of other pathways by serotonin3,4.

D-LSD has also been reported to block the action of noradrenaline on central neurones<sup>5</sup> and to produce stereotypy in rats<sup>6</sup>, a condition which is associated with dopaminergic hyperactivity. Moreover, several recent reports have indicated that a number of ergot derivatives are capable of exerting dopamine-like actions on central neurones in the rat8-10. Recent investigations from this laboratory suggest that adenyl cyclase systems may be involved in the central actions of D-LSD (ref. 11 and K.v H., S.R., and D.F., unpublished). Thus, D-LSD is capable of stimulating adenyl cyclase activity, as well as antagonising the stimulation of this enzyme by serotonin, in cell-free preparations from the rat colliculus. Here we report evidence that D-LSD may act both as an agonist and an antagonist at dopamine receptors in the brain.

The methods employed for the preparation of brain subcellular fractions and measurement of adenyl cyclase activity have been described in detail elsewhere12,13. Brains were obtained from young, adult male rats of an inbred Sprague-Dawley strain. These rats were approximately 6 weeks old and weighed about 225 g. Particulate fractions were prepared from cerebral cortex or corpus striatum.

In relatively low concentration (10 µM), D-LSD, completely blocked the stimulation of cerebral adenyl cyclase activity by a combination of 10  $\mu M$  noradrenaline and 10  $\mu M$  dopamine (Table 1). At these concentrations, the catecholamines produced additive effects on enzyme activity12. Another serotonin antagonist, 2-bromo-D-lysergic acid diethylamide (BOL) also inhibited this response to the catecholamines. Comparable results were obtained when these serotonin antagonists at 100 µM concentrations were tested against equimolar amounts of either noradrenaline or dopamine. D-LSD also inhibited

Table 1 Influence of lysergic acid derivatives on activation of adenyl cyclase by catecholamines in particulate preparations from cerebral cortex of adult rats

The particulate preparations were crude mitochondrial fractions obtained by centrifuging the 1,000g supernatant fluids from cerebral homogenates at 10,000g for 20 min. Adenyl cyclase activity was determined from the conversion of <sup>14</sup>C-ATP to cyclic AMP by a procedure<sup>12</sup> which was based on the method of Krishna et al.<sup>14</sup>. The incubation medium (0.1 ml) contained the following components in the final concentrations indicated: 3.6 mM (0.5 μCi) 8-14C-ATP, 5.0 mM MgCl<sub>2</sub>, 1.0 mM cyclic AMP, 40 mM Tris-HCl (pH 7.3 at 37° C), 10 mM phosphoenolpyruvate, 4  $\mu$ g pyruvate kinase, 15 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (added with pyruvate kinase), 20 mM caffeine, 0.1 mg bovine serum albumin, 0.2 mM EGTA, 5  $\mu$ g phosphatidylserine and 50-100 µg brain protein. Protein was measured by the method of Lowry et al. 15. L-Noradrenaline (10 µM) and dopamine (10 µM) were added together as the hydrochlorides, D-LSD and L-LSD as the free amines and BOL as the bitartrate. Incubation was conducted in air for 5 min. Values for cyclic AMP formed are averages ±s.e. for triplicate samples in a representative experiment. Where indicated, basal values shown were obtained in the presence of the lysergic acid

derivative. \*P < 0.001 for the difference between this value and the value obtained with only the catecholamines added. .

The particulate preparations were obtained by centrifuging the homogenates at 10,000g for 20 min. See Table 1 for other explanations.

\*P<0.001 for the difference between this value and the value obtained with only 10 μM dopamine or 10 µM D-LSD added.  $\dagger P < 0.01$ .

the adenyl cyclase response to noradrenaline or dopamine in particulate preparations from the rat hippocampus, which resembles cerebral cortex in the responses of adenyl cyclase to the catecholamines<sup>13</sup>. Palmer and Burks<sup>16</sup> earlier reported that D-LSD and BOL block the noradrenaline-induced increase in cyclic AMP levels in slices of rat brain.

By itself, D-LSD tended to increase adenyl cyclase activity in the cerebral and hippocampal preparations. This effect was quite small however, (about 15%) and was not always significant. A survey of various brain regions of the rat revealed that cellfree fractions from the corpus striatum contained adenyl cyclase which was reproducibly activated by low concentrations of D-LSD. Significant stimulation could be obtained with concentrations of D-LSD as low as 0.1 µM. Adenyl cyclase activity in comparable fractions from other regions of rat brain (cerebellum, hypothalamus and brainstem) was completely refractory to the stimulatory action of this drug.

Adenyl cyclase activity in particulate preparations from striatal tissue of the adult rat was increased about 30% by  $10\;\mu\text{M}$  D-LSD (Table 2). This was about one-half the activation produced by an equimolar concentration of dopamine. The sensitivity of adenyl cyclase to dopamine in cell-free fractions from rat corpus striatum has been demonstrated earlier<sup>13,17,18</sup>. This region of rat brain is unusually rich in dopaminergic neurones19. The response to 10 µM dopamine in our investigations was completely blocked by the addition of 10 μM D-LSD. In addition, the responses of adenyl cyclase to either 10 μM dopamine or 10 μM D-LSD were almost completely blocked by equimolar concentrations of the antipsychotic dopamine-blocking agents, haloperidol and chlorpromazine. The serotonin antagonists, BOL, 1-methyl-D-lysergic acid diethylamide (MLD) and cyproheptadine were also capable, however, of inhibiting these responses (Table 2, experiment 2). The β-adrenergic blocking agent, propranolol, which markedly inhibits the response of adenyl cyclase to noradrenaline in rat brain cell-free preparations<sup>12</sup>, did not block the stimulation of striatal adenyl cyclase by dopamine or D-LSD. None of these blocking agents by itself, with the exception of p-LSD, increased adenyl cyclase activity in the striatal preparations.

Our findings, combined with earlier observations from this laboratory11, indicate that D-LSD is capable of blocking the interaction of noradrenaline, dopamine and serotonin with their respective receptors in various regions of rat brain. This drug also seems to activate central serotonin and dopamine receptors for adenyl cyclase. Interaction of D-LSD with dopamine receptors was blocked by dopamine-blocking agents (for example, haloperidol) or serotonin antagonists (for example, cyproheptadine), but not by the noradrenaline antagonist, propranolol. These investigations suggest that the hallucinogenic actions of D-LSD may be due to complex agonist and antagonist actions of this drug at central receptors for the several neurotransmitter monoamines.

### The activity of membrane bound enzymes in muscular dystrophic chicks

Tissues from patients with Duchenne muscular dystr/ (DMD) as well as animals with similar inherited2 or mentally produced3 disorders have been shown to

Table 1 Adenyl cyclase in dystrophic chick muscle sarcolemma (pmol cyclic AMP per mg protein per 5 min)									
Activity		embryos			lays			reeks	_

Muscle sarcolemma was prepared from the pectoralis of pooled muscular dystrophic chicks and age-matched white leghorn (No. 26 from Arbor Acres) control chicks by the method of Severson et al. 15. Adenyl cyclase was assayed by measuring the conversion of  $\alpha$ -32P-ATP into 3',5'-cyclic-AMP16. Membrane protein (100-150 µg per assay tube) were incubated for 5 min at 37° C at pH 8.3. Protein was determined by the method of Lowry et al. 12 using bovine serum albumin as standard. Each estimate represents the mean  $\pm$  s.d. of three determinations. Statistical significance of the differences between means was determined using Student's t test.

significant changes in the amount and composition of their membrane lipids. Most pronounced are the increases in cholesterol and sphingomyelin and the decrease in phosphatidyl choline levels. Functional anomalies observed in this disease, such as the impairment in sarcoplasmic reticulum calcium uptake<sup>4</sup> or the changes in the ATPase activity of the sarcolemma<sup>5</sup>, can be related to the lipid disorder.

Both the anomaly in lipid composition and related functional impairments have been observed in tissues other than muscle. For example, erythrocytes from patients with DMD were shown to differ from controls in their lipid composition<sup>1</sup>, in their surface properties as characterised by scanning electron microscope<sup>6</sup> and in membrane ATPase activity<sup>7</sup>. Similarly, in mice with muscular dystrophy the erythrocyte acetylcholine esterase activity was found to be half that of normal controls8. Such observations led to the hypothesis that the genetic basis of Duchenne muscular dystrophy is a defect in lipid metabolism<sup>1,2,9</sup> which may involve the plasma membrane<sup>4,10,11</sup>. Lipids are instrumental not only in the control of membrane selectivity and diffusion across the membrane12 but also in the determination of the activity of membrane bound enzymes and their modulation by hormones and other agents<sup>13,14</sup>. One would therefore expect that if muscular dystrophy is due to a lipid related plasma membrane disorder the activity of membrane associated enzymes and their susceptibility to stimulation should be affected. Involvement of multiple organs would support the hypothesis that the membrane defect is linked to the genetic cause of the disease.

In this study we have investigated adenyl cyclase and ATPase activity associated with the plasma membrane of muscle, liver and erythrocytes from dystrophic chicks and the appropriate controls, under conditions of enzyme stimulation and interference with membrane cholesterol. The adenyl cyclase activity of the muscle sarcolemma from dystrophic chicks differed significantly from that of age-matched normal chicks in several

respects (Table 1). Whereas in the normal chick the specific activity of the enzyme did not vary considerably with age, in the dystrophic it increased progressively to reach, at six weeks, twice the control level. The enhanced GTP (10<sup>-5</sup> M) stimulation of the enzyme in the dystrophic membrane (Table 1) suggests that the differences are due to the expression of enzyme activity rather than to the amount of enzyme present.

Enzyme activity is determined by the microenvironment which controls the conformation of the enzyme, its coupling to the stimulus-receptor site and the substrate accessibility. It has been shown recently that this microenvironment can be affected by amphotericin B, which interacts with cholesterol<sup>14</sup>. Addition of amphotericin B to the sarcolemma depressed the basal enzyme activity of the normal muscle more than that of the dystrophic one. Also, the ratio of the GTP-stimulated to the basal enzyme activity increased after amphotericin B treatment in the normal membrane but not in the dystrophic one (Table 2).

Significant differences were also observed in the adenyl cyclase of liver plasma membrane. As in the muscle of 6-week-old chicks, the basal enzyme activity was elevated in the dystrophic chicks. The percentage stimulation by 10<sup>-5</sup> M glucagon increased after amphotericin B treatment in dystrophic liver but decreased substantially in the normal liver membrane (Table 2). This reiterated the role of the lipid environment in the mediation of the hormone stimulation. Differences between liver and muscle membrane may be due either to tissue specificity or to the mode of action of the different stimulating agents.

In red blood cell membrane, the basal adenyl cyclase activity was lower in dystrophic chicks and showed substantially less stimulation by adrenaline. Digitonin treatment, which extracts membrane cholesterol, reduced the enzyme activity in the normal membrane and totally abolished it in the dystrophic membrane (Table 2).

Muscle sarcolemma was prepared by the method of Severson et al.<sup>15</sup>. Liver plasma membrane was prepared following the procedure of Neville <sup>18</sup> up to step 11 (partially purified membranes). Chick erythrocyte membranes were prepared by using a modification of the procedure of Oye and Sutherland<sup>19</sup>. Adenyl cyclase activity in muscle was assayed as described in Table 1. Liver plasma membrane protein (50–100 μg per assay tube) was incubated for 5 min at 37° C at pH 7.6. Erythrocyte membrane protein (3Q0–350 μg per assay tube) was used under the same conditions. Muscle adenyl cyclase was stimulated with 10-5 M GTP, liver with 10-5 M glucagon and erythrocyte membrane with 10-5 M adrenaline. Muscle and liver plasma membranes were treated with amphotericin B (Squibb intravenous preparation) to yield a concentration of 0.1 mM. Erythrocyte membrane was treated with 1 mg ml-1 digitonin as described by Pohl et al.<sup>13</sup>. Results represent the mean ± s.d.m. of three determinations, Statistical significance of the differences between means was determined using Student's t test. s.d. of the ratios, R, was computed according to σ<sub>R</sub>=[(σ²<sub>τ1</sub>/τ²<sub>2</sub>)+(σ²<sub>τ2</sub>×τ²<sub>1</sub>/τ²<sub>2</sub>)]<sup>1/2</sup>, where R=τ<sub>1</sub>/τ₂ and where values of σ are the respective s.d.

Plasma membrane of muscle and liver and their treatment with amphotericin B, were as described in Table 2. ATPase activity was assayed by incubating 100 µg protein per assay tube for 20 min at 37° C in 40 mM imidazole, 10 mM Tris-HCl, 2 mM Mg (pH 7.4) in the presence of 100 mM NaCl and 10 mM KCl to which either 0.1 mM ouabain or 0.2 mM calcium were added. The ATP concentration was 1 mM. Inorganic phosphate was determined colorimetrically using the ammonium molybdate reaction<sup>20</sup>. The results represent the mean ± s.d. of three determinations. Statistical significance of the differences between means was determined using Student's t test.

The Na+-K+-Mg<sup>2+</sup>-ATPase activity of the dystrophic chick muscle sarcolemma was reduced relative to control and was less stimulated by calcium, as previously observed<sup>5</sup>. Of particular interest were the substantial differences observed in the ATPase activity of the liver plasma membranes. As in muscle, the basal level was lower in dystrophic chicks. Ouabain moderately inhibited the ATPase activity of the normal membrane and slightly enhanced that of the dystrophic one. This difference became more prominent after amphotericin B treatment, when ouabain stimulation was clearly observed in the dystrophic membrane. ATPase stimulation by ouabain has also been observed in erythrocyte membrane from DMD patients<sup>7</sup>. Calcium (10<sup>-4</sup> M) had a similar effect to that of ouabain.

Although it is difficult at present to fit the various differences between the membrane of normal and diseased chicks into a single comprehensive molecular model, the findings support the hypothesis of a generalised membrane defect as an underlying genetic disorder in muscular dystrophy, making it a possible eukaryote membrane mutant. The effects of amphotericin B and digitonin are consistent with the possibility that the basis of this defect is a disorder in lipid metabolism and/or lipid assembly into the plasma membrane.

We thank Ms L. A. Bourret for technical assistance. This work was supported by a grant from the Muscular Dystrophy Associations of America, Inc.

### Voltage clamp studies of glutamate synapse

THERE is considerable evidence that L-glutamate is the excitatory transmitter both at the insect and crustacean neuromuscular junction<sup>1,2</sup>, and also in the vertebrate central nervous system<sup>3</sup>. Here we report the use of the voltage clamp technique to compare the reversal potentials of the conductance increase produced by the excitatory transmitter and the application of L-glutamate at the insect neuromuscular junction. We also investigated the ionic basis of the L-glutamate conductance increase using voltage clamping. These experiments could be carried out accurately because changes in resistance of the electrically excitable membrane caused by changes in membrane potential or by different ionic media do not affect the amplitude of the excitatory junctional currents or glutamate currents.

We studied the extensor tibiae muscle of the metathoracic leg of the locust Schistocerca gregaria. The muscle fibres were clamped using a two microelectrode method, with a potential recording electrode connected to a current passing electrode through a high input impedance amplifier and a feedback amplifier. The smallest muscle fibres which have a length of 1.5 mm and a diameter of 100 µm could be clamped with only 2% error using this technique.

In normal saline (NaCl 170.0, KCl 10.0, CaCl<sub>2</sub> 2.0, HEPES buffer 10.0 mM 1<sup>-1</sup>; pH 6.8), resting potentials of 55-60 mV were recorded. The neurally-evoked responses were reduced in amplitude by the addition of 40 mM Mg to the saline. Stimulation of the excitatory axon to the muscle with a suction electrode produced a transient depolarisation in the unclamped fibre, the excitatory junctional potential (e.j.p.). In the clamped fibre, nerve stimulation produced an inward current, the excitatory junctional current (e.j.c.). An e.j.p. and e.j.c. are shown in Fig. 1. The e.j.c.s had a maximum amplitude of  $1 \times 10^{-6}$  A and an average rise time of 3.9 ms, a much shorter time course than the e.j.p. L-glutamate was applied to the muscle iontophoretically, using high resistance electrodes which obviated the use of braking currents. Iontophoresis of L-glutamate on to the junctional region of the muscle produced a transient inward current of maximum amplitude  $1\times10^{-7}$  A. The rise time of the glutamate currents varied between 20-100 ms, depending on the distance of the iontophoretic electrode from the junction.

Reversal potentials were determined by clamping the e.j.c. and glutamate current at different membrane potentials. The currents were reduced in amplitude as the membrane was depolarised. Actual reversal of the sign of the currents was difficult to achieve because of muscle contraction. Consequently, most reversal potentials were obtained by extrapolation. A linear relationship was obtained for the e.p.c.s and the glutamate currents between 0 mV and 60 mV. The reversal potential of the e.j.c. was  $+3.4 \pm 5.2$  mV (mean  $\pm$  s.d., eight experiments in eight muscles), and the reversal potential of the glutamate current was  $+2.7 \pm 2.4$  mV (mean  $\pm$ s.d., eight experiments in eight muscles). Sometimes a slow outward current was observed following the inward glutamate current when the membrane was depolarised. This is probably due to stimulation of extrajunctional glutamate receptors causing an increase in permeability to Cl (ref. 4).

Takeuchi and Onodera<sup>5</sup> have recently obtained a close agreement between the reversal potentials of the e.p.c. and the glutamate current at the crustacean neuromuscular junction. In insects, reversal values of between -10 mV and -25 mV have been obtained for the glutamate potential and the miniature excitatory postsynaptic potentials at the locust neuromuscular junction<sup>8</sup>. Moreover, reversal values of +6 mV for the excitatory junctional potential and +7 mV for the glutamate potential have also been obtained by reversal of sign at the locust neuromuscular junction (S. G. Cull-Candy and P.N.R.U., unpublished).

Perfusion with Na-free (choline Cl substituted) saline caused a 90-95% reduction in the amplitude of the junctional glutamate current. The reversal potential in the Na-free saline varied between -10 and -15 mV. Changes in the K concentration of the saline between 0 mM and 20 mM did not alter the reversal potential of the glutamate current. A reduction in the external K from 10 to 0 mM doubled the amplitude of the current, however, the opposite of that expected if K contributed to the current. The reversal potential of the junctional current was also unchanged in Cl free saline. Increasing Ca from 2 to 50 mM in normal saline reduced the amplitude of the glutamate current by about 90%, but the small glutamate current which can be recorded in Na-free saline increased in amplitude by up to six times when Ca was increased from 2 to 50 mM.

As the reversal potentials for the e.p.c. and the glutamate current were close to zero, it seemed likely that they were the resultants of a simultaneously occurring inward Na and outward K or Cl currents, as the equilibrium potentials for Na,

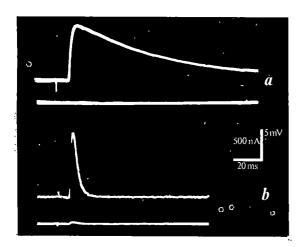

Fig. 1 a, e.j.p. Recorded intracellularly from an extensor tibiae muscle fibre of the locust. b, Upper record, (e.j.c.) recorded from the same muscle fibre with the membrane potential held at the resting level using voltage clamping; lower record, clamped membrane potential. Only a small deviation of 0.1-0.2 mV is seen after nerve stimulation.

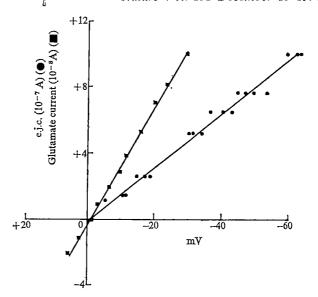

Fig. 2 Relationship between the membrane potential and the amplitude of the e.j.c. (●) and glutamate current (■).

K and Cl in locust muscle have been theoretically calculated as +43 mV, -61 and -50 mV, respectively. The e.p.c.s and acetylcholine currents at the vertebrate neuromuscular junction have reversal potentials between -10 mV and -20 mV, and are generated by simultaneous inward Na currents and outward K currents.

The results of our study, however, suggest that the glutamate current consists only of an inward current carried by Na, with Ca perhaps making a small contribution. K and Cl do not seem to carry any outward current, as alteration of external K and Cl does not change the reversal potential. The absence of any outward current is difficult to explain if the theoretically calculated  $E_{\rm Na}$  for locust muscle is correct. Perhaps the intracellular or extracellular concentrations of Na at the synaptic region are different from the non-synaptic regions, so that  $E_{\rm Na}$  at the synaptic region is close to 0 mV. It is also surprising that a large change in the concentration of external Na only causes a small shift in the reversal potential. This may be due to Ca, which has a very positive equilibrium potential, carrying a greater proportion of the current as external Na is lowered.

Another explanation of the results is that both Na and K do participate in the glutamate current, but the sodium and potassium conductance ratio,  $\Delta g_{\rm Na}/\Delta g_{\rm K}$  varies as the ionic media is altered so that the reversal potential remains at or near zero. Thus as external Na is reduced,  $\Delta g_{\rm Na}/\Delta g_{\rm K}$  and  $\Delta g_{\rm Ka}$  increases, while as external K is reduced,  $\Delta g_{\rm Na}/\Delta g_{\rm K}$  decreases. At the vertebrate muscle end-'plate,  $\Delta g_{\rm Na}/\Delta g_{\rm K}$  stayed constant with most changes in the ionic media, but did decrease markedly when the external K was increased above 10 mM (ref. 9).

We thank Dr S. G. Cull-Candy for useful advice and discussion, and Dr M. D. Burns for assistance with the voltage clamp circuit. This work was supported by a grant from the Science Research Council.

# Synapse formation between clonal muscle

cells and rat spinal cord explants

Although functional neuromuscular junctions have been reported between cultured muscle and spinal cord explants<sup>1-8</sup> or dissociated spinal cord cells<sup>4</sup>, further studies have been hampered because primary cultures represent a mixture of cell types of unknown function. Harris *et al.*<sup>5</sup> tackled this problem by coculturing a neuronal cell line (C1300) from a mouse sympathetic ganglion cell<sup>8,7</sup> with a rat skeletal muscle cell line (L6)<sup>8</sup>. They found regions of high acetylcholine (ACh) sensitivity at points of contact between nerve and muscle, indicating interaction between nerve and muscle<sup>5,9</sup>. So far no functional synapses have been observed in this system. We now report that the L6 muscle cell line can form functional synapses with a competent nerve.

The L6 cell line culture and intracellular recording techniques for monitoring the membrane potential were as reported previously<sup>5,9,10</sup>. Electrophysiology was done at room temperature (20°–24° C) in the following saline (NaCl, 142.6 mM; KCl, 5.6 mM; CaCl<sub>2</sub>, 10 mM; HEPES (N-2 hydroxyethylpiperazine-N'-2-ethansulphonic acid)-NaOH, 5 mM, pH 7.4). In some experiments electrode noise was minimised to 100  $\mu$ V peak-to-peak by using a rather low resistance pipette (50 M $\Omega$ ) and a low pass filter (time constant 0.5 or 1 ms).

Fig. 1 A microscope picture showing a few nerves making contact with an L6 myotube. The bar at the right corresponds to  $50~\mu m$ .

Spinal cords were dissected from 10–20-d-old rat foetuses. Connective tissue was removed and the cord was cut into pieces, about  $0.1 \text{ mm}^3$ , with a pair of needles. Several pieces were placed on a monolayer of myotubes with 0.1–0.5 ml of culture medium and incubated for 1–3 h to allow the explant to stick to the underlying cells. Then modified Eagle's medium<sup>11</sup> supplemented with 10% foetal calf serum was added. During the next few days processes grew out of the explant and several rapidly dividing cells began to be seen, probably fibroblasts and myoblasts. To reduce their proliferation d-arabinofuranosylcytosine  $(5\times10^{-5} \text{ M})$  was added after 3–5 d (ref. 4). After 5–7 d the cultures were returned to the original medium.

At various stages of coincubation the myotubes were penetrated with microelectrodes to record miniature end-plate potentials (m.e.p.p.s.). Figure 1 shows a typical nerve muscle pair in which the muscle is contacted by a few nerves. The m.e.p.p.s. were first observed after 7 d, usually a few per minute. After 2 weeks many myotubes produced m.e.p.p.s. 6-60 per min (Fig. 2 shows sample traces).

The cholinergic nature of these m.e.p.p.s. was demonstrated by applying d-tubocurarine  $(0.3-10\times10^{-7} \text{ M})$ . The half blocking dose was about  $4\times10^{-7} \text{ M}$ ; larger than that found for rat neuromuscular junction  $(3\times10^{-8} \text{ M})$  but similar to that found

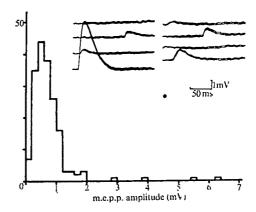

Fig. 2 Amplitude histogram of m.e.p.p.s. Sample recordings of m.e.p.p.s.

for denervated rat muscle<sup>12</sup> and for the potential changes evoked by iontophoretic application of ACh in the L6 cell line<sup>13</sup>.  $\alpha$ -Neurotoxin isolated from an Indian cobra, *Naja naja*, also blocked m.e.p.p.s. at a concentration of  $4 \times 10^{-7}$  g ml<sup>-1</sup>; this is similar to the concentration required to block the response of L6 myotubes to iontophoretically applied ACh<sup>14</sup>.

To determine whether these synapses contain functional acetylcholinesterase the effect of an acetylcholinesterase inhibitor was examined. Edrophonium chloride (Tensilon, Hoffman La Roche<sup>15,16</sup>) at 3.8 to 100 µM did not increase the amplitude, the time-to-peak or the half-decline time of m.e.p.p.s. recorded in cultures after 15–31 d of coincubation. This result agrees with observations on similar systems. Koenig<sup>17</sup> has reported histochemical evidence, however, for the presence of acetylcholinesterase in this system.

The m.e.p.p. amplitude and time course varied over a large range. For example, in the fibre shown in Fig. 2, the amplitudes varied from 0.2 mV to 6.3 mV, the time-to-peak from 6 to 26 ms and the half-decline time from 8.5 to 31 ms. The amplitude histogram which was obtained in the presence of tetrodotoxin  $(6 \times 10^{-6} \text{M})$  to block end-plate potentials (e.p.p.s.), is skewed (in Fig. 2 the coefficient of skewness is 4.6). A similar skewed distribution was found in neuromuscular junctions formed in vitro<sup>4</sup> and regenerating neuromuscular junctions<sup>18,19</sup>.

The mean m.e.p.p. amplitude was also variable from cell to cell. There was a roughly linear correlation between the steady input resistance of the L6 myotube and the mean amplitude of the m.e.p.p.s. recorded in that myotube (in

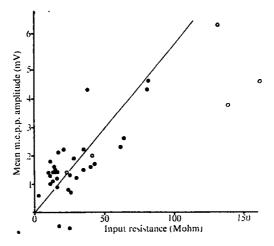

Fig. 3 Correlation between the steady state input resistance and the mean m.e.p.p. amplitude. The m.e.p.p. amplitude is corrected for the resting potential by multiplying by a factor 64/(V-5) (where V is the absolute value of the resting potential in mV). The standard resting potential is taken as -69 mV and the equilibrium potential for the m.e.p.p. was assumed to be -5 mV (ref. 13). Open circles were obtained in preparations treated with La (about 0.1 mM). The straight line is drawn by eye.

Fig. 3 the correlation coefficient is 0.83). The slope of the regression line for L6 myotubes is 0.05 mV for 1 M $\Omega$  of input resistance (Fig. 3). This is 3.7% of that found for the frog (1.33 mV per  $M\Omega$ )<sup>15</sup>. The maximum current during the m.e.p.p.s could be estimated from the maximum rate of rise of the m.e.p.p.s. and the input capacitance of the postsynaptic cells ignoring the current flowing through the resistive component 20. The maximum rate of rise of the average sized m.e.p.p. in the cell shown in Fig. 2 was 0.19 V s<sup>-1</sup> while the input capacitance obtained by analysing the time course of the membrane potential after applying a small amount of hyperpolarising current, was 1.6 nF. The maximum current was then  $0.3 \times 10^{-9}$  A. Assuming an equilibrium potential for the m.e.p.p.s. of -5 mV, the conductance change during average sized m.e.p.p. was calculated to be  $7.6 \times 10^{-9}$  mho (3.5 to  $10.0 \times 10^{-9}$  mho in six cells). This is 5% of the conductance increase measured in frog neuromuscular junction (1.5×10<sup>-7</sup> mho)<sup>21</sup>. This small conductance increase during m.e.p.p.s. could be explained, for example, by a small amount of ACh in one packet or by a low ACh receptor density in the subsynaptic membrane. Patrick et al.14 found 100 receptors per µm2 in non-innervated L6 myotubes, 0.3 to 1.4% of that found at adult end-plates in mammalian striated muscle22-24.

When a nerve bundle in contact with a myotube was stimulated with a suction electrode (tip diameter about 5  $\mu$ m, filled with saline), an e.p.p. was evoked (Fig. 4a). The nerve was stimulated about 50  $\mu$ m from the nerve-muscle contact. There was a relatively long latency (7 ms) between the nerve stimulation and the onset of the e.p.p. Although the e.p.p.s. sometimes failed (seven failures out of 22 consecutive stimulations), no discrete steps of e.p.p. amplitude were seen.

Addition of KCl (20 mM final concentration) did not change the m.e.p.p. frequency although it depolarised the muscle (Fig. 4b). This was the case even in nerve muscle pairs where e.p.p.s. could be evoked by nerve stimulation.

High tonicity causes a large increase in the m.e.p.p. frequency at adult synapses<sup>25</sup> but the addition of sucrose (400 mM) did not increase the m.e.p.p., frequency in this system. A similar

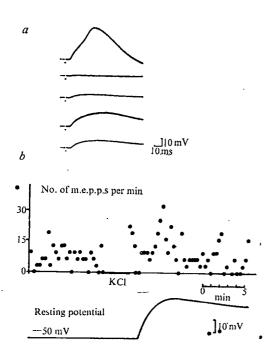

Fig. 4 a, e.p.p.s evoked by stimulating the nerve bundle. Stimulus intensity was kept constant. The top record has a small regenerative potential superimposed on the e.p.p. b, The effect of KCl on m.e.p.p. frequency. A small amount of KCl (1 M) was added to the bath during the time indicated by a bar to a final concentration of 20 mM. The lower trace is the membrane potential of the muscle cell showing the time course of depolarisation.

insensitivity to high KCl and high tonicity was found in newly formed Xenopus neuromuscular junctions in vitro<sup>3</sup>. In several cases lanthanum (about 0.1 mM) increased the m.e.p.p. frequency for a few minutes and then the m.e.p.p.s. disappeared. In most cases, however, lanthanum ions suppressed the m.e.p.p.s without any apparent stimulation. In adult frog neuromuscular junctions lanthanum ions increase the m.e.p.p. frequency for hours before the m.e.p.p.s. finally disappear<sup>28</sup>.

The electrophysiological properties of the synapses formed between the L6 cell line and spinal cord explants are similar to those reported in chick primary cultures<sup>1, 2, 4</sup>.

Thus a clonal muscle cell line adapted to continuous cell culture can make a synapse with a suitable nerve. Previous failures to detect functional synapses between L6 myotubes and the neuroblastoma cell line must have been due to the incompetence of the nerve. The availability of many independently derived nerve, glia and muscle cell lines<sup>27,28</sup> will make possible an investigation of the requirements of synapse formation.

# Rapid reversal of internal Na<sup>+</sup> and K<sup>+</sup> contents of synaptosomes by ouabain

THERE is evidence that a number of drugs which have profound effects on the central nervous system (CNS) may do so by altering membrane bound (Na++K+)-dependent ATPase and/or Na+ pump activities. For example, ouabain which is an inhibitor of neuronal (Na++K+) dependent ATPase¹ and Na+ pump activity², can impair short term memory in small doses³ and produce convulsions when larger doses are administered intraventricularly⁴.

It is generally considered that the synaptic region of the neurone is especially sensitive to the actions of drugs. In the case of drugs which modify  $(Na^++K^+)$ -dependent ATPase activity, it is interesting that this enzyme is found in abundance in synaptosomal preparations. Moreover, synaptic terminals in the CNS, which are generally 1 µm or less in diameter, would have very small internal volumes so that alterations in Na+ pump activity might be expected to cause relatively rapid changes in the concentrations of Na+ and K+ inside the terminals. In contrast, the squid giant axon, with its much larger internal volume, and therefore larger reservoir of K+, seems to be fairly resistant to Na+ pump inhibition insofar as it maintains its resting potential even after the Na+ pump has been inhibited by ouabain or metabolic inhibitors for over an hour<sup>2,7</sup>.

We have found that ouabain reversed the normal  $Na^+$  and  $K^+$  contents of synaptosomes within 1 min of exposure to the drug, indicating that presynaptic terminals might be particularly sensitive to drugs which influence  $Na^+$  pump activity.

Synaptosomes were prepared from the brains of 2 male Wistar rats (200–250 g) and isolated on sucrose density gradients as described previously<sup>8</sup>, before being finally resuspended with 0.5 ml of ice-cold 0.32 M sucrose. The synaptosomes were then incubated in media containing NaCl, KCl, CaCl<sub>2</sub>, MgCl<sub>2</sub> and Tris-HCl and the effects of 1 mM ouabain on the Na<sup>+</sup> and K<sup>+</sup> contents determined as described in Fig. 1.

Figure 1a shows that 1 mM ouabain caused a significant reduction in synaptosomal  $K^+$  content (paired t test) at 30 s with a maximal effect by 1 min. Synaptosomes gained Na<sup>+</sup> during incubation (Fig. 1b) but ouabain increased further the Na<sup>+</sup> content after 1 min (paired t test) with a maximal effect achieved after 3 min. At time zero, the  $K^+/Na^+$  ratio was 1.51 for the control synaptosomes (Fig. 1c) which compares favourably with the value of 1.78 found previously for synaptosomes immediately after isolation on a discontinuous sucrose density gradient<sup>12</sup>. During incubation for 1 min, this ratio decreased somewhat to 0.93 for the controls but ouabain completely reversed the  $K^+/Na^+$  ratio to 0.39 by 1 min.

These results clearly indicate that ouabain can very quickly reverse the Na<sup>+</sup> and K<sup>+</sup> contents of synaptosomes. If, as much evidence suggests, synaptosomes are functionally intact presynaptic nerve terminals<sup>13-15</sup>, and if one can extrapolate from these *in vitro* experiments to the *in vivo* situation, it would seem that alterations of synaptic Na<sup>+</sup> pump activity might very quickly change the internal Na<sup>+</sup> and K<sup>+</sup> contents of synaptic terminals, possibly because of the very small internal volumes of the terminals. This rapid change in Na<sup>+</sup> and K<sup>+</sup> content could in turn affect the resting membrane potential<sup>7</sup>, the generation of action potentials<sup>7</sup>, the release and reuptake of neurotransmitters<sup>6,16</sup> and even protein synthesis<sup>17,18</sup> in the presynaptic terminal. Thus, one might expect synaptic transmission to be particularly susceptible to alterations in neuronal Na<sup>+</sup> pump activity.

This work was supported by a grant from the Medical Research Council of Canada.

J. T. ARCHIBALD THOMAS D. WHITE

Department of Pharmacology, Dalhousie University, Halifax, Nova Scotia, Canada

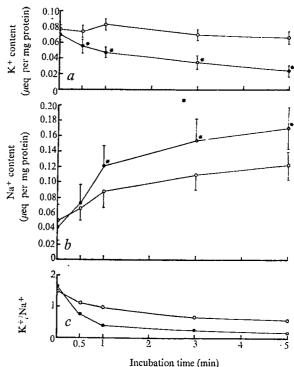

Fig. 1 Time course for the effect of ouabain on the Na<sup>+</sup> and K<sup>+</sup> contents of synaptosomes. Incubation medium (2 ml) containing 120 mM NaCl, 3 mM KCl, 3 mM MgCl<sub>2</sub>, 2 mM CaCl<sub>2</sub>, 20 mM Tris-HCl(pH 7.4) and sometimes 1 mM outbain were prewarmed to 37° C under air in a 10 ml conical flask in a shaking incubator. To avoid any effects of ouabain on glucose uptake which might indirectly influence synaptosomal Na<sup>+</sup> pump activity, glucose was omitted from the incubation medium. At zero time, 0.10 ml of synaptosomal suspension was added and the incubation continued; the reaction was stopped by removing and filtering 0.5 ml of medium on a Millipore filter (0.45  $\mu$ m pore size and 2.5 cm diameter) and washing with 10 ml, ice-cold medium containing 260 mM sucrose, 3 mM MgCl<sub>2</sub>, 2 mM CaCl<sub>2</sub> and 20 mM Tris-HCl (pH 7.4). This washing procedure, which took approximately 20 s, did not seem to rupture the synaptosomes. A 1.5 cm diameter disk containing the synaptosomes was cut out from the filter and Na<sup>+</sup> and K<sup>+</sup> were eluted overnight with 0.6 ml of 15 med l<sup>-1</sup> lithium diluent solution (Instrumentation Laboratory, Inc., lithium nitrate standard). This hypotonic treatment releases the Na<sup>+</sup> and K<sup>+</sup> contained in osmotically sensitive compartments of the synaptosomes. The Na<sup>+</sup> and K<sup>+</sup> contents of the diluent were determined with an IL model 143 flame photometer and the values corrected for the Na+ and K+ eluted from the filter itself by subtracting the amount of Na+ and K+ released into diluent from filters which had been treated as above except that no synaptosomes were present in the incubation medium. Na<sup>+</sup> contamination due to trapping of incubation medium in the extracellular space of the synaptosomes on the filters was determined in the following manner. Synaptosomes were incubated as before but 0.01 ml of 35S-sulphate (1 mCi ml<sup>-1</sup>) as an extracellular marker<sup>8</sup> was added immediately before filtering and washing. The radioactivity in the filter was determined by scintillation counting and compared with the radioactivity-present originally in 0.01 ml of the <sup>35</sup>S-sulphate solution to give the percentage contamination of the filter and synaptosomes by incubation medium. This estimate was performed for various concentrations of synaptosomal protein including a blank which contained no synaptosomes. The latter value was subtracted from the values obtained with synaptosomes present to give the amount of contamination in the extracellular space and these values were used to calculate the percentage contamination by incubation medium. The extrasynaptosomal Na<sup>+</sup> contamination from the incubation medium was calculated and subtracted from the total Na<sup>+</sup> content of the synaptosomes on the filter to give the actual Na<sup>+</sup> content of the synaptosomes. Contamination by extracellular  $K^+$  was not corrected because of the small amounts of  $K^+$  present in the original incubation media. The final ion K<sup>+</sup> present in the original incubation media. The final for contents were expressed as µeq ion per mg synaptosomal protein. Protein was determined by the Hartree<sup>10</sup> modification of the method of Lowry et al.<sup>11</sup>, <sup>35</sup>S-sulphate was supplied by New England Nuclear Corp., Ltd., Montreal and ouabain by the Sigma Chemical Co., St Louis. a, K<sup>+</sup> content; b, Na<sup>+</sup> content; c, ratio of K<sup>+</sup>: Na<sup>+</sup>; O, control; •, 1 mM ouabain. Each point represents the mean ±s.e. of 12 determinations (six experiments).

\*Ouabain treatment is significantly different from the control Ouabain treatment is significantly different from the control (P < 0.05, paired r test).

### Coordinate and differential in vitro syntheses of two RNA polymerase subunits

THE B subunit of Escherichia coli RNA polymerase—one of three subunit types  $(\alpha, \beta, \beta')$  in the enzyme core structure—is specified by a genetic locus, rif (ref. 1). Specialised transducing phages which carry the rif region have been isolated<sup>2,3</sup>. If DNA is extracted from these phages, it can be used to direct the synthesis of the B subunit in vitro in a coupled transcription/ translation system<sup>4,5</sup>. It has been suggested that other RNA polymerase structural genes may also be in this region of the chromosome<sup>6</sup>. Recent genetic evidence shows that the  $\beta$  and  $\beta'$ subunits are produced from a single transcriptional unit in vivo7. DNA extracted from three independently isolated rif transducing phages however, failed to direct the synthesis of any detectable \( \beta' \) molecules in vitro in the coupled systems previously described<sup>4.5</sup> (Fig. 1a). Here I describe a coupled system which synthesises  $\beta$  and  $\beta'$  in vitro with equal efficiency from rif transducing phage DNA.

The new method involves the use of modifications in the preparation of bacterial extracts (S30s) similar to those developed by Wilcox et al. who used them to maximise the synthesis of arabinose isomerase in vitro using λh<sub>80</sub>dara template DNA<sup>8</sup>. The data presented in Fig. 1 provide strong evidence that both  $\beta$  and  $\beta'$  subunits can be synthesised in the modified system, using  $\phi 80d_7 rif^7$  DNA as a template. Two newly-synthesised proteins migrate upon electrophoresis in sodium dodecylsulphate polyacrylamide gels to positions coincident with those of marker bands for  $\beta$  and  $\beta'$ . These proteins are specifically precipitated by serum prepared against highly purified E. coli RNA polymerase (Fig. 1). Thus these proteins are antigenically related to purified RNA polymerase, and have apparently identical molecular weights to those of the  $\beta$  and  $\beta'$  subunits.

If the proteins made in vitro are indeed RNA polymerase subunits, then DNA-containing mutations which alter polymerase structural gene expression in vivo should also affect the synthesis of the proteins in vitro. We have previously described a class of mutations (rif° mutations) which are candidates for  $\beta$  structural gene mutations. The rif° mutations

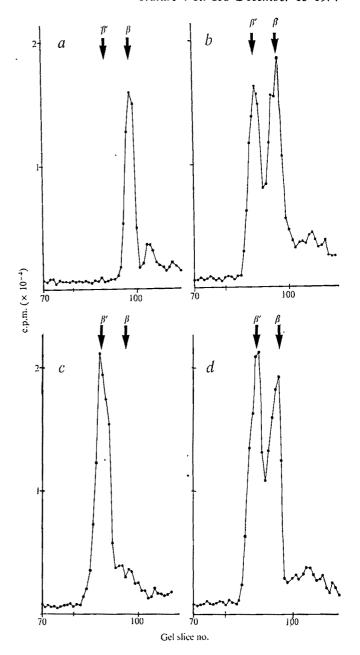

Fig. 1 Cell free protein synthesising systems containing type 1 or type 2 S30s were run as previously described with the addition of 15 mg ml<sup>-1</sup> of polyethylene glycol and 0.2  $\mu$ mol disphosphopyridine nucleotide. 0.1 ml systems contained 0.3 mCi of <sup>3</sup>H-L-leucine, specific activity 60 Ci mmol<sup>-1</sup>, 10  $\mu$ g of template DNA, and either 2 nmol E. coli transfer RNA from a non-suppressing (su<sup>-</sup>) strain or 2 nmol of tRNA enriched for the suppressor SuIII tRNA<sup>10</sup>. After incubation, the systems were diluted to 0.4 ml with buffer incubation, the systems were diluted to 0.4 ml with buffer having the same salt composition as the cell free system<sup>4</sup>, mixed thoroughly, and centrifuged at 4° C at 40,000g for 15 min. The supernatant was decanted into a tube containing 20  $\mu$ I of antiserum prepared against highly purified RNA polymerase. This serum is highly specific for the participapolymerase. This serum is nightly specific for the participation of RNA polymerase and its subunits (S.A., unpublished). After 12 h at 4° C the precipitate was collected by centrifugation at 40,000g for 30 min. The pellet was resuspended in 50  $\mu$ l of sample buffer<sup>4</sup>, and was run on sodium dodecylsulphate polyacrylamide gels as previously described<sup>4</sup>, except that 2 mm thick slab gels<sup>14</sup> were substituted for the tubular that 2 mm thick stab gels" were substituted for the fibrilar ones. The gels were stained, sliced, and counted for radio-activity as previously described. The arrows show the position of the stained marker bands for β and β'. a, Type 1 S30, Φ80d<sub>7</sub>rif' DNA; b, type 2 S30, Φ80d<sub>7</sub>rif' DNA; c, type 2 S30, Φ80d<sub>7</sub>rif'-B115 DNA; d, type 2 S30 plus suIII enriched tRNA, Φ80d<sub>7</sub>rif'-B115 DNA.

Table 1 The synthesis of arabinose isomerase and  $\beta$  galactosidase in vitro using type 1 and type 2 S30 cell extracts

	Arabinose acti		β-galactosidase* activity		
DNA template λh <sub>80</sub> dara λh <sub>80</sub> d lac	Type 1 S30 < 0.04 < 0.04	Type 2 S30 3.2 < 0.04	Type 1 S30 <0.01 12		

Type 1 S30 cell extracts were prepared as described<sup>11</sup> by lysis in an Aminec French Pressure Cell at 5,000 pounds per square inch pressure. Cell extracts prepared by alumina grinding, were also used and had identical properties to type 1 S30s. Type 2 S30s were prepared as described but with French Cell pressures further reduced, so that 30% of the bacteria remain unbroken (600–1,000 pounds per square inch). Both types of S30 were active for protein synthesis as shown by their ability to promote  $\beta$ -galactosidase synthesis from  $\lambda h_{80}d$  lac template DNA (Table 1). The protein synthesis mixtures<sup>8</sup> were incubated for 80 min at 35.5° C with µg ml<sup>-1</sup> of template DNA. Arabinose isomerase activity was dependent on *de novo* synthesis of the regulatory product directed by the ara C gene<sup>8</sup>. The C gene product can also be made using type 1 S30's (ref. 13).

\*Arabinose isomerase assays<sup>8</sup> and β-galactosidase assays<sup>9</sup> are expressed as μmol of substrate converted h<sup>-1</sup> ml<sup>-1</sup> of *in vitro* system; 1 ml assay mixtures contained 0.1 ml of the in vitro system.

eliminate the expression of the rifampicin sensitivity phenotype, which is known to be associated with the β structural gene<sup>1</sup>. I have transfered a rifo mutation of the chain terminating class,  $rif^{\circ}$ -B115  $_{amber}$ , from the host chromosome to the  $\phi 80d_{7}rif^{\circ}$ transducing phage by recombination (Austin, in preparation). DNA extracted from the recombinant phage, φ80d<sub>2</sub>rif°-B112, produces no  $\beta$  peak *in vitro* but still directs  $\beta'$  synthesis (Fig. 1c). If purified E. coli transfer RNA, enriched for mutant suIII tRNA is added to the system<sup>10</sup> the synthesis of the β protein is restored (Fig. 1d). Thus rif o-B115 is a suppressible nonsense mutation which eliminates the expression of the β gene. As it has no apparent effect on  $\beta'$ , a gene distal to the  $\beta$  gene in the same operon7, rif°-B115 is probably a β structural gene mutation.

The difference in results obtained with the in vitro system by changing the type of \$30 used is notable. The use of the modified (Type 2) S30 is, within the limits of detection of my assays, an absolute requirement for the synthesis of  $\beta'$  from φ80d<sub>7</sub>rif<sup>\*</sup> DNA, and of arabinose isomerase from φ80dara DNA (Fig. 1, Table 1). The original, however, (Type 1), S30s (ref. 11) suffice for the synthesis of  $\beta$  subunit from  $\phi 80d_2 rsf^{\tau}$ (Fig. 1). A second product of the ara operon, ribulokinase, can also be made efficiently using type 1 S30s (ref. 12). Thus the in vitro system can show a striking discrimination between two products which at least in vivo, are the products of a single messenger RNA. Both the rif and ara operon show this effect. This suggests that the effect may have some general relevance to the production of proteins from polycistronic messengers. I am now investigating whether the discrimination occurs at the level of transcription or translation. The present system should provide an assay for attempts to purify a discriminating agent from S30 extracts.

I thank E. Bikoff for a generous gift of suIII enriched tRNA. This investigation was funded by a National Science Foundation grant to J. Beckwith.

### Alteration of melanocytes by DNA in White Plymouth Rock chickens

SINCE 1944 when it was first demonstrated that the pneumococcal transforming principle was DNA1, several investigators have reported evidence suggesting genetic alteration of warmblooded animal cells by DNA-mediated transformations<sup>2-7</sup>. Attempts to transform the plumage coloration characters in White Plymouth Rock embryos have been unsuccessful<sup>8</sup>. The genetically lethal melanocytes in the White Plymouth Rock chicken do not appear abundantly or thrive for long in the feather germ. They degenerate before they can deposit a significant number of melanin granules in the feather-forming cells. Using nucleoprotein from the Harco chicken, a standard cross between the Barred Plymouth Rock hen and the Rhode Island Red rooster, I have extended the life span of the melanocytes in White Plymouth Rock embryos.

Nucleoprotein was extracted from about 1 g (wet weight) of feather anlage, from 10-d-old Harco chicken embryos. The tissue was suspended in a solution of 0.25 M sucrose (pH 7.4) and 1 mM EDTA at a 1:9 (w/v) ratio of tissue to sucrose. The mixture was homogenised in a tissue grinder with an inhibitor of DNase (NaF, 0.044 M). Nucleoprotein was extracted with 2 M sodium chloride as described by Zamenhof10, except that the mixture was left at 4° C for only 2 h to avoid damage to DNA. The nucleoprotein was suspended in 4 ml of normal saline and divided into two parts: one part was left untreated and to the second part, crystalline pancreatic DNase (0.1 mg ml<sup>-2</sup>) and MgCl.6H<sub>2</sub>O (5 mM) were added. The preparations were incubated at 25° C for 1.5 h and then 0.04 ml was injected into small extra-embryonic veins of 5-d-old

Fig. 1 Light micrograph of melanin granules in the feather anlage from the head of a 14-d-old White Plymouth Rock embryo, which was injected with DNA on the day 5 of incubation  $(\times 100)$ .

White Plymouth Rock embryos. By this time the melanoblasts have migrated from the neural crest into the skin<sup>11</sup>.

Twelve of the nineteen embryos injected with nucleoprotein survived beyond day 14 of incubation. Starting from this time and continuing until birth, nine of these embryos were examined at 2-d-intervals. The host embryo's melanocytes would have degenerated by this time if left undisturbed. The remaining three embryos were allowed to hatch. Patches of pigmented feathers were found on five of the embryos and on the juvenile down of one newborn chick (Fig. 1). Their coats were otherwise white.

The active component in the transforming material seems to be DNA because no DNase-treated preparation induced pigmented feathers. Thus treatment of White Plymouth Rock embryos with DNA carrying a marker for full-lifed melanocytes resulted in the development of pigmented feathers in six out of twelve cases.

I thank Barbara M. O'Donnell for suggestions and discussion, J. Gray for technical assistance and J. Sanes for his support.

### In vitro maturation of precursors of 5S ribosomal RNA from Bacillus subtilis

THE ribosomal RNA (rRNA) molecules both of prokaryotes and of eukaryotes are not the immediate products of DNA transcription. Rather, precursors of the mature RNA species undergo a series of nucleotide modifications and/or cleavage events 1,2. Only limited information is available concerning the mechanics of and rationale for post-transcriptional tailoring of RNA because of the large sizes of the precursor molecules and consequent difficulty in evaluating their nucleotide sequences.

By virtue of its small size (about 120 nucleotides), 5S rRNA is convenient for study but its maturation is not always as complex as that affecting the high molecular weight rRNA molecules (16S and 23S rRNA, in prokaryotes). In Escherichia coli, for example, the precursor of 5S rRNA (p5) is converted to the mature molecule (m5) by an exonuclease<sup>3,4</sup> rather than a specific endonuclease, which probably is responsible for maturation of 16S and 23S rRNA. In Bacillus subtilis, however, metabolism of 5S rRNA apparently mimics that of the larger rRNA molecules. In the absence of protein synthesis (presence of chloramphenicol) B. subtilis accumulates two precursors of 5S rRNA, designated p5<sub>A</sub> (180 nucleotides) and p5<sub>B</sub> (150 nucleotides). Both are converted independently to m5 rRNA, which in this organism is composed of 118 nucleotides. We here report that maturation of p5A and p5B is effected in vitro by a partially purified, specific cleavage enzyme, which we denote as RNase M5.

Incubation of purified 32P-labelled p5A and p5B with partially purified RNase M5 from B. subtilis yields several products. Figure 1 displays polyacrylamide gel electrophoretograms of the

purified substrates (Fig. 1a and b) and the products of the cleavage reaction (Fig. 1c and d). The  $p5_A$  molecule yields three products, one coincident with added 3H-labelled m5 rRNA in electrophoretic mobility, a second about forty nucleotides in length (designated F1) and a third composed of 22 nucleotides (designated F2). Two-dimensional electrophoretic analysis (data not shown) of T1 and pancreatic RNase digests of the 5S material generated during the reaction shows that it possesses the same 5' (p-U-U-U-G-) and 3' (-A-A-G- $C_{OH}$ ) termini as 5S rRNA obtained from ribosomes; the molecules are identical. The products of p5<sub>B</sub> cleavage include one component identical in size and structure to the added 3H-m5 rRNA and a second fragment having the same electrophoretic mobility and, as it proved, the same detailed structure as F2. Also derived from p5<sub>B</sub> is a component which is heterogeneous in size (about 8-15 nucleotides) which we have not characterised in detail.

Evaluation of the T1 RNase digestion products of the fragments released during the reaction defines their origin in the precursors (Fig. 2). Of particular note is that F1 contains -U-U-U-U-U-G<sub>OH</sub> (Fig. 2a), the 3' terminus of F1 and of p5<sub>A</sub> (M. Rosenberg, unpublished), whereas F2 yields p-U-G-(Fig. 2b), the 5' terminus of both precursors. F1 therefore must

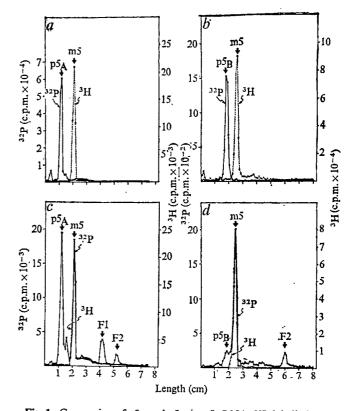

Fig. 1 Conversion of p5<sub>A</sub> and p5<sub>B</sub> to m5 rRNA. <sup>32</sup>P-labelled p5<sub>A</sub> or p5<sub>B</sub> prepared as described previously were incubated at 37° C for 15 min in the presence or absence of Sup 2 RNase M5 from B. subtilis 168 in 0.01 M Tris-HCl, pH 7.5, 0.05 M NH<sub>2</sub>Cl, 0.005 M MgCl<sub>2</sub>. Reaction was halted by addition of sodium dodecyl sulphate to 1% and ethylene diamine tetraacetic acid to 0.01 M, then 3H-labelled m5 rRNA was added as a size marker 0.01 M, then <sup>3</sup>H-labelled m5 rRNA was added as a size marker and products were resolved by electrophoresis through 8% polyacrylamide gels<sup>5</sup>. Materials migrating in gels between the m5 and F1 regions are products of nonspecific degradation. a, <sup>32</sup>P-p5<sub>A</sub> plus <sup>3</sup>H-m5 rRNA (no enzyme); b, <sup>32</sup>P-p5<sub>B</sub> plus <sup>3</sup>H-m5 rRNA (no enzyme); c, <sup>32</sup>P-p5<sub>B</sub> incubated with Sup 2 RNase M5 preparation; d, <sup>32</sup>P-p5<sub>B</sub> incubated with Sup 2 RNase M5 preparation. Sup 2 was prepared as follows: 2 gm of B. subtilis 168 cell paste was resuspended in 4 ml buffer SB (0.05 M Tris-HCl, pH 7.5, 0.06 M NH<sub>4</sub>Cl, 0.01 M MgCl<sub>2</sub>, 0.0001 M EDTA-Na<sub>2</sub>, 0.0001 M dithiothreitol, 5% glycerol) containing 10 μg ml<sup>-1</sup> DNase. Cells were disrupted with a French press, and the lysate was diluted twofold with buffer SB and cleared by centrifugation at 20,000 r.p.m. (Sorvall SS-34 rotor) for 20 min. The supernatant is Sup 0. Ribosomes were pelleted from Sup 0 by centrifugation at 40,000 r.p.m. somes were pelleted from Sup 0 by centrifugation at 40,000 r.p.m. (Spinco 40 rotor) for 2 h, resuspended in SB, adjusted to contain 0.2 M NH<sub>4</sub>Cl, and again pelleted. The supernatant is Sup 2.

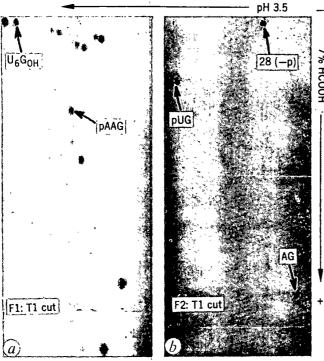

Fig. 2 Two-dimensional electrophoresis of T1 RNase digests of F1 and F2. Fragments designated F1 and F2 were generated from p5<sub>A</sub> by incubation with Sup 2 and resolved by gel electrophoresis as described in Fig. 1. Following elution from gels, the fragments were digested completely by T1 RNase and resulting oligonucleotides were resolved by two-dimensional electrophoresis on cellulose acetate at pH 3.5, followed by diethylaminoethyl paper at pH 1.9, as detailed by Sanger and Brownlee<sup>6</sup>, a, RNase T1 digest of in vitro F1; b, RNase T1 digest of in vitro F2.

represent the 3' and F2 the 5' terminal, precursor-specific segments of p5<sub>A</sub>. The scission events release 5'-phosphoryl and 3'-hydroxyl termini. Recovery of these fragments establishes that RNase M5 is a specific endonuclease.

We have not yet rigorously purified RNase M5 of *B. subtilis*, but substantial information regarding the enzyme is available (M.L.S., and N.R.P., unpublished). Apparently, a single catalytic activity is responsible for removing both the 5' and 3'

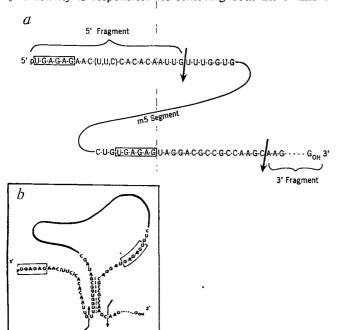

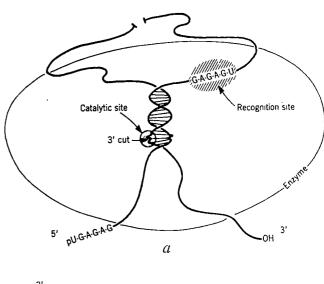

Fig. 3 Partial nucleotide sequence of p5<sub>A</sub> of B. subtilis; a, as a linear molecule and, b, with the 5' and 3' terminal regions of the m5 portion of the precursor juxtaposed in an antiparallel, duplex stalk.

terminal, precursor-specific segments of p5<sub>A</sub> and p5<sub>B</sub>. This is suggested by our inability to separate 5' and 3' cleavage activities by chromatography on DEAE cellulose or by zonal sedimentation through sucrose gradients. Moreover, the 5' and 3' cleavage activities display identical inactivation kinetics. RNase M5 is a large protein, 5-6S in size, corresponding to a molecular weight of 1 × 10<sup>5</sup>-1.5 × 10<sup>5</sup>. Maximal activity requires as well the presence in reactions of at least one relatively low molecular weight component, possibly a ribosomal protein. As a single enzyme removes both the 5' and 3' terminal precursor-specific sequences, it is likely that single catalytic and recognition sites are involved in interaction with the substrate molecules. In principle, therefore, it is possible to suggest features of the precursor molecules which interact with RNase M5 by identifying structural similarities in the vicinities of the two endonucleolytic cuts.

The nucleotide sequences of the precursor and mature 5S rRNA molecules from B. subtilis are almost completely determined (M.L.S. and N.R.P., and S. M. Weissman et al., unpublished). Relevant portions of the p5<sub>A</sub> molecule are shown in Fig. 3. The 5' and 3' terminal regions of the m5 portion of the precursor are juxtaposed in an antiparallel, duplex stalk. This feature is common to all 5S rRNA molecules so far examined and probably exists both in solution and in the ribosome. The points at which endonucleolytic cleavage occur are indicated. It is noteworthy that the cuts at the 5' and 3' termini of the molecule are spatially quite near to each other when the hydrogen-bonded stalk is constructed, and in fact the points of scission probably are within a duplex region. It seems unlikely, however,

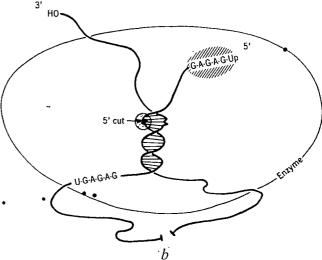

Fig. 4 Alternative models for the interaction of  $p5_A$  with RNase M5 (for an explanation of a and b see text).

that both endonucleolytic cuts are effected at the same time because the catalytic site on the enzyme surface very probably must consider the polarity of the phosphodiester bond being acted upon. The two bonds to be cleaved would present opposite polarities upon simultaneous inspection by a catalytic site.

It is evident from Fig. 3 that the sequences in the immediate vicinities of the endonucleolytic cuts are dissimilar; RNase M5 is unlikely to act at independent substrate sites on this basis. The sequence -U-G-A-G-A-G-, however, lies 16 nucleotides 5' removed from both points of cleavage. One of these sequences is at the 5' terminus of a precursor-specific segment whereas the second lies within the body of the m5 portion of the molecule. The probability of random assignment of two identical hexameric sequences equidistant from two given points (the cleaved sites) is about 2.4×10<sup>-4</sup>, so we suppose that this sequence constitutes at least part of that feature of the precursors which is recognised by the cleavage enzyme. If both the duplex stalk and the U-G-A-G-A-G sequence are considered to be involved in orientation of the substrate, then structural symmetry about the bonds to be cleaved is apparent, as is diagrammatically depicted in Fig. 4. Figure 4a positions the U-G-A-G-A-G- in the body of the m5 sequence at a 'recognition site' on the enzyme surface, and at the 'catalytic site' is placed the phosphodiester bond whose cleavage will release the 3' terminal, precursor-specific segment.

Alternately (or following release of the fragment) (Fig. 4b), the substrate could be inverted and rotated about the helical axis of the stalk to place the 5' terminal U-G-A-G-A-G into the 'recognition site'; this could place at the 'catalytic site' the phosphodiester bond whose hydrolysis releases the 5' terminal precursor-specific segment. Both U-G-A-G- sequences are aligned at the recognition site on the enzyme surface with the same chemical polarity and, similarly, the phosphodiester bonds to be cleaved are positioned at the catalytic site with the same polarity. The structural simplicity of the 5S rRNA molecule thus permits tentative identification of features within one type of polynucleotide which may interact in a highly specific fashion with a protein. The actual involvement of the proposed recognition-alignment elements and their relationships to the phosphodiester substrate bonds during the cleavage reaction are experimentally testable.

### Candidate for immunoglobulin D present on murine B lymphocytes

ALTHOUGH the original discovery of human IgD is almost ten years old1, it is only very recently that a possible function for this class of immunoglobulin has been suggested. Present in normal human serum in very small amounts2, IgD is found on the surface membrane of relatively large numbers of human peripheral lymphocytes, in particular those obtained from cord blood and the circulation of patients with chronic lymphatic leukaemia3-7. IgD is frequently associated with IgM on the same cell<sup>5-7</sup> and this, together with the fact that the frequency of IgD-bearing lymphocytes is higher in cord blood than adult blood<sup>4,5</sup>, suggests a fundamental role for IgD, either as a primitive recognition unit or for regulation of the immune response. Were this to be so, then clearly IgD would be expected to occur in species other than man. Here we present the identification of an immunoglobulin present on the surface of mouse splenic lymphocytes which is not IgM, but which has the predicted characteristics of IgD.

ê

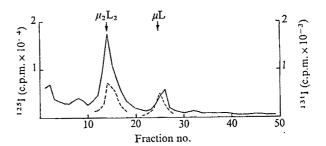

Fig. 1 Surface immunoglobulin of murine splenic lymphocytes. Spleen cell suspensions of 4-6-week-old female CBA mice were labelled with <sup>125</sup>I by the lactoperoxidase catalysed procedure<sup>8</sup>, washed once in phosphate-buffered saline (PBS) and then lysed for 10 min at 0°C in 1% (w/v) Nonidet P40 in PBS. The centrifuged lysate (4,000g×10 min), containing 95% of the total TCA-precipitable radioactivity, was dialysed against 1% (w/v) Nonidet P40-PBS in the cold. Surface-labelled immunoglobulin was precipitated by the addition of a polyspecific rabbit antimouse Ig serum (10 µl) followed by goat anti-rabbit IgG (100 µl). The precipitate was washed three times with ice cold 0.5% (w/v) Nonidet P40 in PBS, twice with ice cold PBS, and then dissolved Nonidet P40 in PBS, twice with ice cold PBS, and then dissolved in 4% (w/v) sodium dodecyl sulphate (0.1 M iodoacetamide) 0.05 sodium phosphate, pH 7.0, by heating at 100° C for 5 min. A sample of mouse myeloma MOPC 104E IgM was labelled with <sup>131</sup>I (ref. 16), partially reduced to  $\mu_2 L_2$  and  $\mu L$  by treatment with 1 mM dithiothreitol for 60 min at room temperature, alkylated with 10 mM iodoacetamide, and then added to the isolated <sup>125</sup>I-cell surface Ig to serve as an internal marker for the gel analysis (4.25% (w/v) polyacrylamide gel containing for the gel analysis (4.25% (w/v)) polyacrylamide gel containing 0.1% (w/v) sodium dodecyl sulphate). Following electrophoresis, the gel was sliced into 1 mm segments and radioactivity determined. Values were corrected for cross channel spill, and plotted with the top of the gel on the left hand side of the figure.

—, <sup>125</sup>I incorporated into cell surface lg; ---, <sup>131</sup>I-labelled internal marker.

Spleen cell suspensions containing more than 95% viable cells (trypan blue exclusion) were labelled with 125 by the lactoperoxidase-catalysed procedure8, and the surface immunoglobulin was prepared and analysed on sodium dodecyl sulphate (SDS) gels9 with addition of an internal marker (131I-labelled IgM<sup>10</sup> partially reduced to  $\mu_2L_2$  and  $\mu L$ ). As has been previously described11,12, we found a major portion of radioactive cell surface immunoglobulin in that part of the gel corresponding to the IgMs (µ2L2) subunit of IgM (Fig. 1). In addition, however, there was a significant radioactive peak running very slightly in advance of the µL subunit, but which contained heavy and light chains on reduction (see Fig. 2) and must therefore be an HL subunit.

Following reduction and alkylation both the H<sub>2</sub>L<sub>2</sub> and HL subunits were shown to contain two distinct species of heavy chain, there being one component with the mobility (and therefore size) of the internal 131I-µ chain marker, and another which migrated faster than  $\mu$  chain, but slower than  $\gamma$  chain (Fig. 2). The proportion of radioactivity found in the smaller (faster migrating) heavy chain was lower in the sample of reduced <sup>125</sup>I-surface H<sub>2</sub>L<sub>2</sub> (Fig. 2a) than the reduced <sup>125</sup>I-surface HL (Fig. 2b).

We discount the possibility that the heterogeneity of surface

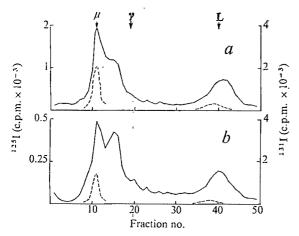

Fig. 2 Heavy chain heterogeneity of surface immunoglobulin of murine splenic lymphocytes. Sections of the gel shown in Fig. 1 containing the  $H_2L_2$  and HL components were eluted with 2% (w/v) sodium dodecyl sulphate (2mM dithiothreitol) 0.05 M sodium phosphate, pH 7.0. The eluate was heated for 15 min at  $100^{\circ}$  C in order to ensure reduction of all disulphide bridges, and then alkylated by addition of iodoacetamide to 10 mM. The resulting material was then applied to 10% (w/v) polyacrylamide gels containing sodium dodecyl sulphate to resolve the heavy chain components. In these conditions the  $^{131}I_{-}\mu_2L_2$  and  $\mu$ L originally added as internal markers for the first gel are also extracted and reduced, thereby providing internal markers for  $\mu$  and L chains in the second separation in the 10% acrylamide gels. The gels were fractionated, counted and plotted as given in the legend to Fig. 2. The position of  $\gamma$  chains was assessed by running a mixture of totally reduced  $^{131}I_1$ -labelled mouse IgM (MOPC 104E) and IgG2a (Adj.PC5) on a parallel gel. a, Reduced, surface labelled  $H_2L_2$ ; b, reduced, surface labelled  $H_L$ . ——,  $^{125}I_1$  incorporated into cell-surface Ig; ——,  $^{131}I_2$ -labelled internal marker.

Ig results from the presence of T-lymphocytes in the spleen cell suspension as similar results were obtained when spleen cells from nude mice were analysed by the same techniques. In addition, peripheral T-lymphocytes purified by passage of spleen cells through nylon wool columns<sup>13</sup> did not contain detectable amounts of surface immunoglobulin using the methods described above.

Reconstruction experiments were performed to check for degradation of  $\mu$  chain-containing material during the preparation of labelled surface Ig. Both  $^{126}\text{I-labelled}~\mu_2L_2$  and  $\mu\text{L},$  prepared by partial reduction of MOPC 104E IgM, could be recovered unchanged when added to spleen cells and then carried through the procedures outlined above for isolation of cell surface immunoglobulin. The HL subunits found on the surface of splenic lymphocytes, therefore, do not result from reductive depolymerisation of  $\mu_2L_2$  during isolation. Reduction of the recovered  $^{125}\text{I-}\mu_2L_2$  and  $^{126}\text{I-}\mu\text{L}$  yielded heavy chains entirely corresponding in size to untreated  $\mu$  chain. We are therefore confident that the observed heavy chain size heterogeneity of cell surface immunoglobulin does not result from degradation of  $\mu$  chain during the isolation procedure.

A possible explanation for the heterogeneity of surface immunoglobulin is that there is a precursor-product relationship between the various species observed. Such a relationship could either reflect a biosynthetic pathway or metabolic turnover of membrane-associated immunoglobulin. In the first case the HL subunit would be an intermediate in the biosynthesis of H<sub>2</sub>L<sub>2</sub>, and the small heavy chain would be a partially glycosylated  $\mu$  chain requiring the addition of further sugar residues for completion. In the alternative situation, the direction would be expected to be towards degradation of H<sub>2</sub>L<sub>2</sub> to HL and proteolysis of the heavy chain. We have ruled out either possibility by culturing surface-labelled spleen cells in vitro for 0-12 h. The absence of any form of precursorproduct relationship was clearly indicated by the fact that the ratios of H<sub>2</sub>L<sub>2</sub> to HL and large heavy chain (that is, a μ chain) to small heavy chain determined at time zero remained the

same in cell surface and released immunoglobulin recovered at all times of incubation. This experiment demonstrated also that the half lives of all the immunoglobulin species present on the cell surface are similar, a value of 10 h being determined.

We then pursued the possibility that the small heavy chain was derived from a class other than IgM by using antisera of defined class specificity for isolation of surface immunoglobulin. Antibodies specific for  $\gamma 1$ ,  $\gamma 2a$  and  $\alpha$  chains did not precipitate immunoglobulin from detergent-solubilised, surface-labelled splenic lymphocytes. On the other hand, specific anti-µ chainprecipitated H2L2 and HL containing heavy chain corresponding only in size to authentic, secreted  $\mu$  chain (Fig. 3a). This material may therefore be identified as  $\mu$  chain with certainty. When the supernatant from the anti-µ precipitation was further reacted with polyspecific anti-(mouse Ig), however, the H<sub>2</sub>L<sub>2</sub> and H1 species precipitated were predominantly composed of the small heavy chain (Fig. 3b). We may therefore conclude that there is present on the surface of murine splenic lymphocytes a heavy chain larger than the  $\gamma$  chain, yet smaller than the  $\mu$  chain, which is not precipitated with antisera to  $\gamma$ , α or μ chains, but which is reactive with a polyspecific antiserum to mouse Ig. As the small heavy chain was not precipitated by anti-(µ chain), the possibility that it is an incompletely glycosylated µ chain<sup>14</sup> is ruled out.

The inescapable conclusion is that this heavy chain, which accounts for about 40% of heavy chain isolated from surface-labelled spleen cells, represents a hitherto undescribed class of

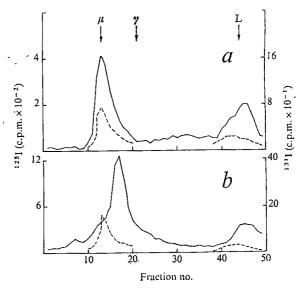

Fig. 3 Two different heavy chain classes present on the surface of murine splenic lymphocytes. Spleen cells were labelled with <sup>125</sup>I as described in the legend to Fig. 1. They were washed once in Eagle's medium containing 10% foetal calf serum, resuspended in the same medium at 2×10<sup>7</sup> cells ml<sup>-1</sup>, and then incubated at 37° C in an atmosphere of 5% CO<sub>2</sub> in air for 6 h. At the end of the incubation period, the cells were 95% viable (trypan blue exclusion). The medium, containing released cell surface immunoglobulin, was separated from the cells by centrifugation (400g, 10 min), adjusted to contain 1% (w/v) Nonidet P40, and dialysed against 1% (w/v) Nonidet P40 in phosphate buffered saline. To the non-diffusate was added a specific rabbit anti-(mouse μ chain) serum (10 μl) and goat anti-(rabbit IgG) serum (100 μl). The resulting precipitate was removed by centrifugation, and the supernatant was further reacted with polyspecific rabbit anti-(mouse Ig (40 μg) to ensure complete precipitation of mouse Ig. Both precipitates were washed and analysed in 4.2% (w/v) polyacrylamide gels as described in the legend to Fig. 1. The H<sub>2</sub>L<sub>2</sub> containing regions of both gels were eluted, reduced and alkylated, and analysed on 10% (w/v) polyacrylamide gels as described in the legend to Fig. 2. a, Reduced cell surface H<sub>2</sub>L<sub>2</sub> precipitated with rabbit anti-(mouse μ chain); b, reduced cell surface H<sub>3</sub>L<sub>2</sub> prepared from the supernatant of the precipitation with rabbit anti-(mouse μ chain) by addition of rabbit anti-(mouse Ig).

—, <sup>125</sup>I incorporated into cell-surface Ig; ---, <sup>131</sup>I-labelled internal marker.

immunoglobulin in the mouse; the most obvious surmise is that it corresponds to the human IgD class. To support this suggestion we note the similar mobility on SDS-polyacrylamide gels of human δ chain<sup>2</sup> and the novel heavy chain of mouse lymphocytes described above. This newly described mouse immunoglobulin, which we shall now refer to as IgD, is also similar to human IgD2 in its marked susceptibility to proteolytic degradation (E.R.A. and R.M.E.P., unpublished). A similar conclusion has also been drawn by others (E. S. Vitetta and J. W. Uhr, unpublished).

Contrary to our expectation, however, was the finding of  $\mu$  chain, but not  $\delta$  chain, in foetal liver (16 d embryos) and neonatal spleen and liver. In addition, splenic lymphocytes of 6 week and 6 month old mice contained similar amounts of  $\delta$  chain, the ratio of  $\mu$ : $\delta$  being about 3:2. This could mean that the expression of IgD in the mouse is subsequent to the appearance of IgM. If this is not the case, then IgD-bearing lymphocytes must arise in organs other than spleen or foetal liver. Perhaps relevant to this point is the fact that IgD constitutes the major immunoglobulin class present on murine lymph node cells, where the  $\mu$ : $\delta$  ratio was found to be 1:3.5-4.0.

It is certainly intriguing that spleen and lymph node cells differ markedly in terms of the relative amounts of  $\mu$  and  $\delta$ chains present on their surfaces. In this respect we may note that spleen cells, but not lymph node cells, respond to lipopolysaccharide (G. Janossy and R.M.E.P., unpublished), and that spleen cells secrete largely IgM, whereas the major product of lymph node cells is IgG15. The presence or absence, however, of a functional relationship between these separate observations remains to be determined. Whether the molecular heterogeneity of total cell surface Ig is reflected in a similar pattern on individual cells is not known. Nonetheless, a relationship between this observed heterogeneity and regulation of the B-lymphocyte response to antigen is suggested.

E.R.A. thanks the Consejo Nacional de Ciencia y Tecnologia de Mexico for financial support. We thank Jain Hunter and Gill Priestley for their assistance in the experimental work.

#### Immunoglobulin of T lymphoma cells is an integral membrane protein

IMMUNOGLOBULINS, predominantly 7S IgM molecules (molecular weight ~ 200,000), are associated with the plasma membranes of lymphocytes1-3 and considerable evidence suggests that these proteins function as receptors for antigen<sup>4-6</sup>. If these molecules are themselves integral parts of the lymphocyte membrane or are strongly associated with integral proteins they may transmit antigen-induced signals through the membrane and initiate cell activation. It has been proposed that the antigen-combining site of T cell IgM protrudes from the cell surface, but that the Fc portion bearing the characteristic antigenic determinants of the heavy chain is not accessible to large molecules in the solvent<sup>2,7</sup>. If these proposals are correct, then surface immunoglobulin of T cells might be considered an integral constituent of the plasma membrane8.

Cultured mouse WEHI-22 T lymphoma cells represent monoclonal T cells which synthesise and express surface IgM-like immunoglobulin<sup>2,5,9</sup> showing certain collaborative properties<sup>10</sup>. If immunoglobulin is an integral protein of WEHI-22 plasma membrane, it should be possible to isolate the plasma membrane and to detect immunoglobulin associated with it. Because preparation of purified membranes involves large dilution factors and prolonged washing<sup>11</sup>, it is likely that loosely associated peripheral proteins would be lost during the process. In this communication we provide evidence that immunoglobulin is detectable on purified plasma membrane of WEHI-22 cells and is therefore strongly associated with the T cell membrane.

Plasma membranes were prepared from unlabelled WEHI-22 cells to which were added 5×107 surface radioiodinated WEHI-22 cells. The cells were radioiodinated by a modification<sup>12</sup> of the lactoperoxidase method developed for labelling

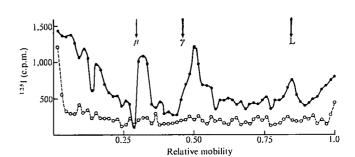

Fig. 1 Polyacrylamide gel electrophoresis in SDS of 125 I-labelled polypeptide chains of immunoglobulin isolated from membranes of T lymphoma cells of the line WEHI-22. Membrane protein (225 µg) was solubilised in 500 µl 1% Nonidet P40-6M urea. The solution was dialysed against PBS and subsequently the nondialysable protein was radioiodinated using chloramine-T (ref. 15): to 100 µl membrane protein solution (0.45 mg protein ml<sup>-1</sup>) were added 10 µl carrier-free <sup>125</sup>I (100 mCi ml<sup>-2</sup>) and 5 µl chloramine-T (1 mg ml<sup>-1</sup>) and then the mixture was held at 4° C for 1 h. The reaction mixture was fractionated by gel filtration on Sephadex G100 in 0.5% Nonidet P40 in PBS. Fractions of the <sup>125</sup>I-labelled high molecular weight peak were pooled and PBS added to a total volume of 3.0 ml. Aliquots (200 µl) of this 125I-labelled membrane protein solution were precipitated with the specific precipitation system which consisted of mouse IgM (100 µl of a concentration of 0.1 mg ml<sup>-1</sup>) and rabbit antiserum to mouse IgM (100 µl of antiserum diluted 1 in 2) or with the control precipitation system which consisted of fowl IgG (100 µl of a concentration of 0.1 mg ml<sup>-1</sup>) and rabbit antiserum to fowl IgG (100 µl of antiserum diluted 1 in 2). The coprecipitates were washed three times with PBS, dissolved in a buffer containing 10% glycerol, 5% mercaptoethanol, 3% SDS in 0.125 M Tris-HCl, pH 6.8 which was 6M in urea and then analysed by polyacrylamide gel electrophoresis (10% acrylamide, 0.25% bisacrylamide) in a discontinuous buffer system according to the method of Lagranghia Specific precipitates: method of Laemmli<sup>18</sup>.  $\bullet$ , Specific precipitates;  $\bigcirc$ , control precipitates;  $\mu$ ,  $\gamma$  and L refer to positions of standard immunoglobulin chains.

lymphocytes<sup>13</sup>. The label was used solely to monitor the distribution of plasma membrane during fractionation and the subsequent analysis of the membrane proteins (Fig. 2). The cells were disrupted using a modification of the "pump" described by Wright et al.14 and the plasma membrane was separated according to the method of Crumpton and Snary<sup>11</sup>. The purified membrane which exhibited a 35-fold enrichment in specific 5'-nucleotidase activity relative to the initial cell homogenate was solubilised in 1% Nonidet P40-6M urea. Approximately 95% of the radioactivity was obtained in solution. This solution was dialysed against PBS and the nondialysable protein radioiodinated using the chloramine-T method (ref. 15 and legend to Fig. 1). The reaction mixture was fractionated by gel filtration on Sephadex G-100. Approximately 70% of the added 125I-iodide was associated with high molecular weight protein as judged by gel filtration.

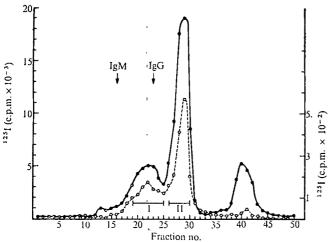

Fig. 2 Gel filtration on Sepharose 6B of solubilised membranes of T lymphoma cells of the line WEHI-22. Two procedures were used: a, membranes were solubilised in 1% sodium deoxycholate (Merck) in 20 mM Tris-HCl, pH 8.2 (0.5 mg membrane protein per ml solvent; 1 h at room temperature) and the Sepharose 6B column (55 cm $\times$ 0.8 cm) was developed in the same solvent ( $\bullet$ ). b, Membranes were solubilised in 10M urea-1.5 M acetic acid (0.5 ml membrane protein per ml solvent; 2 h at 30° C) followed by dialysis against Tris-NaCl, pH 8.0; 15% of the original membrane bound counts were soluble in Tris-NaCl as judged by centrifugation. Separation was performed on a Sepharose 6B column of identical dimensions, the elution buffer was PBS (O). The fractions indicated I and II obtained from the separation using procedure B were pooled, concentrated by ultrafiltration and radioiodinated using chloramine-T<sup>15</sup>. These fractions were assessed for the presence of Ig by coprecipitation (legend to Fig. 1). IgM and IgG represent the position of intact marker proteins (molecular weights 900,000 and 150,000, respectively) resolved under these conditions

The presence of Ig in the solubilised 125I-labelled membrane was ascertained by immunological precipitation. We found that the specific immune precipitate possessed  $7.7\pm0.5\times10^3$ c.p.m. whereas the control precipitate gave  $1.1\pm0.1\times10^3$ c.p.m. This difference shows that the plasma membrane contains Ig. This interpretation is supported by polyacrylamide gel electrophoretic analysis of the immune precipitates in buffers containing sodium dodecylsulphate (SDS)16. Furthermore, the results of these analyses closely resembled those reported elsewhere for WEHI-22 surface Ig isolated from lactoperoxidase-iodinated whole cells (ref. 2 and D.H., J.J.M. and A. W. Harris, submitted for publication). Radioiodinated plasma membrane Ig contained components resembling μ-chain and L-chain in their electrophoretic mobilities (Fig. 1). A third component was also present with a mobility consistent with a molecular weight of about 40,000. Studies to be reported in detail elsewhere revealed that this component has properties similar to those predicted for the surface membrane receptor for the Fc-portion of exogenous IgG (ref. 17). A considerable amount of material with mobilities greater than that corresponding to a molecular weight of 105 was observed in all

polyacrylamide gels of homologous immune precipitates derived from preparations of plasma membrane radioiodinated using chloramine-T. The amount and distribution of this material was, however, variable and studies of its nature were not pursued further; similar material was observed in Ig isolated from murine B cells radioiodinated using chloramine-T (E. White, and J.J.M., unpublished observations).

These results establish that light chains and μ-like heavy chains were present in surface membrane Ig of WEHI-22 cells; but, they do not provide any information regarding the intact state of the molecule. This problem has been approached by fractionating solubilised membrane by gel filtration on Sepharose 6B (legend to Fig. 1) and radioiodinating the fractions eluted in positions corresponding to molecular weights of  $<10^5$  and between  $1\times10^5$  and  $3\times10^5$  in order to ascertain the presence or absence of free polypeptide chains and 7S Ig respectively. These fractions are illustrated in Fig. 2. The fractions termed I and II were pooled as indicated and radioiodinated using chloramine-T (ref. 15). Immunoglobulin estimated by immune precipitation, was found only in the 100,000-300,000 molecular weight fraction  $(3.6\pm0.6\times10^3$ c.p.m. specific;  $1.1\pm0.1\times10^3$  c.p.m. control). No Ig was detected in the lower molecular weight fraction  $(0.9 \pm 0.2 \times 10^3)$ c.p.m. specific;  $1.1\pm0.2\times10^3$  c.p.m. control). There was insufficient material in the elution position of 19S IgM to enable analysis of this fraction. These results are consistent with the previous observation that the Ig associated with the surface of T cells exists primarily as 7S units2,5 rather than as free polypeptide chains18.

Surface Ig of mouse T lymphoma cells of the line WEHI-22 was found to exist as a 7S IgM unit which was bound to the plasma membrane sufficiently strongly to resist dissociation or elution during the disruption of the cells and the isolation of the plasma membrane. These results are consistent with the proposals that either T cell immunoglobulin is itself an integral membrane protein or that it is tightly associated with another component buried in the lipid bilayer of the membrane. Similar proposals also apply to the surface IgM of the human lymphoblastoid cell line BR18 (M. J. Hayman, and M.J.C., unpublished observations).

then rises steadily to reach a plateau by about day 5 although the cells continue in log phase growth for a further 5-6 d.

Inhibition of agglutinating activity was attempted with monospecific antisera directed against each of the major classes of human Ig heavy and light chains, in experiments of the type shown in Fig. 1. The results with three of the lines were clear cut (Table 1), indicating that the activity is associated with Ig of class IgM\(\lambda\) in the supernatants of HIL1, ANA1 and PEN2. In the case of BRIs the agglutinating titre of the supernatant is low and the findings less easy to interpret. Anti-k serum consistently inhibits agglutination, but both anti-A and anti-M (and occasionally anti-G) also seem to have some inhibitory effect. Attempts to identify Igs by immunoelectrophoresis of concentrated supernatants from cell lines ANA1, PEN2 and BRI8 were only partially successful. The presence of  $\lambda$  light chains in material from ANA1 and PEN2 was confirmed but no other heavy or light chains could be demonstrated. Failure to detect Igs, when their initial concentration in culture supernatant is low, is common with this technique<sup>2</sup>.

#### Antibody activity associated with immunoglobulins synthesised by human lymphoblastoid cell lines

Antibody activity has not previously been detected in association with immunoglobulins synthesised spontaneously by human lymphoblastoid cell lines in vitro. One reviewer has commented "if some antibody activity was to be found, the established cell lines would be a fascinating tool for the study of homogenous antibodies". We here report such a finding.

In the course of studies on immunoglobulin (Ig) production in vitro, by means of a haemagglutination-inhibition assay2, supernatants from four human lymphoblastoid lines (of more than 60 tested) were found to agglutinate glutaraldehyde-fixed Ig-coated sheep erythrocytes in the absence of anti-Ig serum. Details of the four lines are given in Table 1. It was established that the Ig coating is irrelevant to the agglutination reaction and that supernatants from these four lines (but not from others) will agglutinate sheep or human erythrocytes fixed with glutaraldehyde or formaldehyde. There is no detectable activity against fresh erythrocytes of either species, nor against glutaraldehyde or formalin-fixed calf erythrocytes. Tanned or glutaraldehyde-fixed horse erythrocytes agglutinate spontaneously in the presence of unused culture medium (Ham's F10 with 10% tryptose phosphate broth and 20% foetal calf serum). The agglutinating activity against glutaraldehyde-fixed sheep red cells seems to be independent of temperature over the range 4° C to 37° C.

The kinetics of agglutinin production have been studied in cell line PEN<sub>2</sub>. Some activity is detectable within 24 h of resuspending the cells at 105 ml<sup>-1</sup> in fresh medium. The titre Dilutions of antiserum

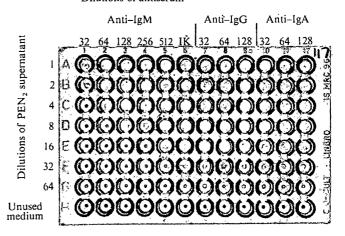

Fig. 1 Haemagglutination carried out in round-bottomed wells of microtest II plate (Linbro plastics). Reciprocal dilutions of PEN<sub>2</sub> supernatant (in fresh culture medium containing 20 foetal calf serum) are recorded on the left; reciprocal dilutions of monospecific anti-human Ig chain sera (in physiological saline) are recorded above. One drop of diluted supernatant was mixed with 1 drop of diluted antiserum in each well and 30 min later 1 drop of a 1 % suspension (in saline) of sheep red cells, previously fixed in 2.5% glutaraldehyde, was added. The cells were allowed to settle overnight at room temperature. Agglutination is shown by the absence of a dark central pellet of erythrocytes. Inhibition of the agglutination reaction becomes more marked with increasing concentrations of anti-IgM serum. There is no inhibition demonstrable with anti-IgG or anti-IgA sera.

† Maximum dilution of supernatant giving positive result against 1% suspension of glutaraldehyde-fixed sheep erythrocytes. Titres against human cells or against formalin-fixed sheep erythrocytes are usually lower. Recently, using an Q.25 % suspension of glutaraldehyde-fixed sheep

erythrocytes, titres of up to 1:256 have been observed in PEN<sub>2</sub> supernatants.

‡ Anti-G, Anti-A and Anti-M, Monospecific goat anti-human heavy chain sera (Technicon); Anti-K and Anti-L, monospecific rabbit antihuman light chain sera (Hoechst); GPK, OxRBC, guinea pig kidney and ox erythrocyte stroma extracts for infectious mononucleosis ('Monospot') tests (Ortho diagnostics).

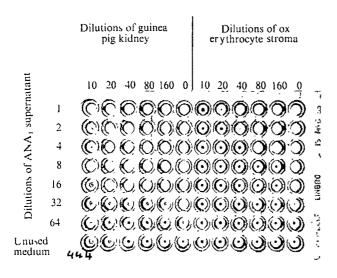

Fig. 2 Haemagglutination test set up as in Fig. 1. Reciprocal dilutions of ANA, supernatant are recorded on the left. One drop of the diluted supernatant was mixed with one drop of guinea pig kidney or ox erythrocyte stroma extracts (Ortho Diagnostics) in saline (reciprocal dilutions shown above) in each well of the test plate. One drop of glutaraldehyde-fixed sheep erythrocytes (1% suspension in saline) was added 20 min later and the plate left overnight at room temperature. Progressive inhibition of agglutination with increasing concentrations of ox erythrocyte stroma is clearly demonstrated. Guinea pig kidney extract has no apparent effect on the agglutination reaction.

Preliminary studies on the physical properties of the erythrocyte-agglutinating factor from PEN2 supernatants show that it is precipitated by 10-40% saturated ammonium sulphate. It can be isolated as a single sharp peak from a Sephadex G200 column and the major fraction bands with a human IgM marker on a 10-40% sucrose gradient. There is a minor peak of agglutinating activity in the lower molecular weight range, possibly representing depolymerised IgM.

There seems to be no common factor in the lines or in their origins which distinguishes these four cultures from others established and maintained in identical conditions. The four lines are readily distinguished from each other by cytogenetic and isoenzyme analysis. A second line, ANA2, was established from the same blood sample which gave rise to ANA1. No erythrocyte agglutinating activity is detectable in its supernatant.

The original sera from the donors of PEN<sub>2</sub>, ANA<sub>1</sub> and HIL<sub>1</sub> were recovered from storage at  $-20^{\circ}$  C along with samples from 20 other donors including three cord bloods and nine from patients with Klinefelter's Syndrome (karyotype 47,XXY or 49,XXXXY). Lymphoblastoid cell lines had been established from most of these control donors. The sera were tested for agglutinating activity against glutaraldehyde-fixed sheep red cells. More than half (including those from the donors of PEN<sub>2</sub> and HIL<sub>1</sub>) gave weak reactions at dilutions of 1:5 or 1:10. These were considered non-specific. Four Paul-Bunnel positive samples from patients with infectious mononucleosis agglutinated the fixed sheep cells at titres of 1:160 to >1:640. As in the Paul-Bunnel reaction, this agglutination was inhibited by adsorption with ox erythrocyte stroma but not with guinea pig kidney extract3. Similar tests on the four cell line supernatants show that those from ANA<sub>1</sub> and HIL<sub>1</sub> consistently behave like infectious mononucleosis sera (Fig. 2), but agglutinating activity in PEN2 or BRI8 supernatants seems not to be inhibited by ox erythrocyte or by guinea pig kidney extracts.

These preliminary data suggest that EB virus, which is implicated both in infectious mononucleosis4 and in the proliferation of human lymphoblastoid cell lines in vitro<sup>5,6</sup>, may be responsible for the production of agglutinins directed against fixed sheep erythrocytes by at least some of these lines.

Further work is in progress to isolate and compare the agglutinins synthesised by the four cell lines under study.

#### Tolerance induction with bovine y globulin in mouse radiation chimaeras depends on macrophages

THE injection of adult mice with ultracentrifuged heterologous y globulin induces immunological unresponsiveness to a subsequent injection of the globulin incorporated in incomplete or complete Freund's adjuvant1. It has been reported that inbred strains of mice differ in their susceptibility to the induction of unresponsiveness. Bovine y globulin (BGG), human γ globulin (HGG) and rabbit γ globulin (RGG) easily produce tolerance in C57BL/6 and DBA/2 mice but not in BALB/c mice<sup>2,3</sup>. Passage of BGG through the circulation of BALB/c mice (but not DBA/2 mice) gives preparations which produce a high degree of tolerance in the recipient mice suggesting that strain differences in the induction of tolerance are related to the capacity of the reticuloendothelial system to process the immunogenic component in ultracentrifuged soluble BGG (sBGG). Here, we report that the administration of carrageenin, which is known to be toxic for macrophages destroys the resistance to tolerance induction in BALB/c mice. Also spleen and bone marrow cells transferred from BALB/c mice to irradiated DBA/2 mice to form chimaeras, do not show characteristic BALB/c resistance to induction of tolerance until twelve weeks after transfer.

To test immune responsiveness to BGG we used previously described procedures<sup>2,3</sup>. One week after intraperitoneal (i.p.) injection of 2.0 mg sBGG for tolerance induction the mice

Table 1 Effect of various doses of carrageenin on the induction of unresponsiveness with 2 mg in BALB/c mice

sBGG. • • • 4×0.5 mg every second day before	11	6	2
saline None			5 5

Kappa carrageenin (Marine Colloids) was dissolved in saline by heating, and an appropriate dose administered in 0.5 ml., 2.0 mg sBGG was administered 24 h after the last injection of carrageenin. One week later the mice were immunised with 100 µg BGG-CFA and then challenged with 2 µg 126I-BGG. were immunised with 100 μg BGG in complete Freund's adjuvant (CFA). Five days later they were given 0.1% KI in their drinking water. One week after immunisation the mice were challenged with 2 μg <sup>125</sup>I-BGG and whole body counts obtained daily in a gamma scintillation counter. Two milligrams sBGG readily induces tolerance in DBA/2 mice. BALB/c mice exhibit complete resistance to the induction of unresponsiveness at this dose and show subsequent clearance rates of <sup>125</sup>I-BGG indistinguishable from the immune control animals.

Carrageenin, a polysaccharide isolated from seaweed, known to be toxic for macrophages<sup>4</sup> but not for lymphocytes<sup>5,6</sup> was tested for its effect on tolerance induction by administration to BALB/c mice, before the injection of sBGG. Pretreatment with carrageenin favours tolerance induction in BALB/c mice (groups 1 and 2) whereas the immune response of the mice treated with BGG-CFA only (group 3) was not affected (Table 1). Thus, carrageenin-sensitive cells seem to be a critical factor in susceptibility to the induction of unresponsiveness.

We studied further this difference using cell transfer experiments. DBA/2 mice share the major histocompatibility loci (H-2<sup>d</sup>) with BALB/c mice and are poor responders to most bone marrow allografts<sup>7,8</sup>. Previous spleen cell transfer experiments showed that although the animals were true chimaeras with respect to their content of donor T and B cells at 4 weeks after lethal irradiation and reconstitution, they responded to the induction of tolerance to sBGG like normal animals of recipient strains<sup>9</sup>. We wished to examine the change with time of the susceptibility to the induction of unresponsiveness in lethally irradiated (850 rad) DBA/2 mice reconstituted with 2 × 10<sup>7</sup> BALB/c bone marrow cells from 8-week-old donors.

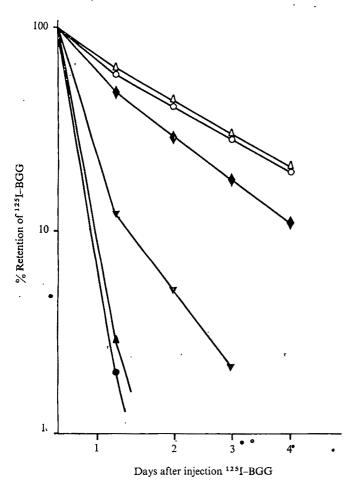

Fig. 1 Induction of tolerance in DBA/2 mice 12 weeks after the reconstitution with BALB/c bone marrow cells. Clearance rate 2 μg <sup>125</sup>I-BGG in normal (N) and irradiated-reconstituted (I-R) animals: Δ, N, saline-CFA; ⊙, I-R, saline-CFA; ♠, N, 2 mg sBGG+BGG-CFA; ▼ I-R, 2 mg sBGG+BGG-CFA; ▲ N, BGG-CFA; ♠ I-R, BGG-CFA.

This selected host-donor combination displayed practically no secondary disease and low mortality (5 out of 45 animals, in 4 months after irradiation).

As in previous spleen cell transfer experiments, animals tested for tolerance induction 4 weeks after reconstitution with BALB/c bone marrow cells showed non-immune clearance characteristic of normal DBA/2 mice made tolerant (Table 2). Six weeks after reconstitution the results were similar. But after 12 weeks 10 out of 11 animals exhibited the characteristic resistance to tolerance of the BALB/c donors. At that time 2 mg sBGG failed to induce tolerance in DBA/2 animals reconstituted with BALB/c cells although the same dose induced tolerance in the non-irradiated controls (Fig. 1). No significant difference was observed in the ability of BALB/c marrow-reconstituted and normal DBA/2 mice to clear 2 µg 125I-BGG when pretreated with CFA only, or to respond to an immunising dose of BGG-CFA (Fig. 1).

Table 2 Induction of unresponsiveness to sBGG in irradiated DBA/2 mice reconstituted with BALB/c bone marrow cells

Immune responsiveness	Weeks after reconstitution				
	4	6	12		
Tolerant	8	5	0		
Partially tolerant	0	1	1		
Immune	0	0	10		

Mice are irradiated with 850 rad and reconstituted with  $2\times10^7$  bone marrow cells. They were injected with 2 mg sBGG 4, 6, or 12 weeks after reconstitution. One week later the mice were immunised with 100  $\mu$ g BGG-CFA and then challenged with 2  $\mu$ g <sup>125</sup>I-BGG.

These results demonstrate that the resistance of BALB/c mice to tolerance induction resides in a cell population sensitive to the action of carrageenin. The most likely candidate would be macrophages in the reticuloendothelial system which are responsible for effectively processing the immunogenic portion of BGG and initiating a response in some clones before tolerance is induced in the remainder. On subsequent immunisation these primed cells proceed to make antibody and the mice seem on balance to be immune. The literature is full of observations demonstrating an enhanced immune response following stimulation of macrophages and suppression following their destruction<sup>10</sup>.

What is somewhat surprising is the failure of spleen and bone marrow cell grafts to effect reconstitution of an irradiated recipient in the sense that they would then behave like donors in respect to tolerance induction. Balner<sup>11</sup> however, has shown that after irradiation and bone marrow grafting, host type macrophages in the peritoneum were not replaced to any major extent for a significant time. The behaviour of our irradiation chimaeras agrees with this observation. Four weeks after grafting, animals possessed T and B cells of donor origin but continued to behave as normal hosts with respect to ease of tolerance induction<sup>9</sup>. We have demonstrated that even 6 weeks is insufficient for functional reconstitution but after 12 weeks (Table 1) the behaviour of the chimaeras was now almost totally like the donor as to tolerance induction.

These results provide strong confirmation of the existence of a decision making event at the level of the macrophage that determines whether in a particular strain of mice the injection of an antigen such as BGG will result in tolerance or immunity.

#### Separation of T effector cells in humoral and cellular immunity

THE precise relationship between thymus-derived (T) helper cells in the antibody response and T effector cells in cellular immunity is not clear. Both cell functions have closely related dose response curves<sup>1</sup>, kinetics of sensitisation<sup>1</sup>, susceptibility to antibody suppression<sup>1-3</sup> and anatomical distribution<sup>4</sup>. Bone marrow-derived (B) lymphocytes can be stimulated for antibody synthesis by a stimulus from immunocompetent allogeneic<sup>5</sup> or xenogeneic<sup>6</sup> lymphoid cells. These observations have led to the hypothesis that T helper cells are identical to cytotoxic T cells and act on B cells by secreting a factor which stimulates them to produce antibody. Liew and Parish have reported, however, that T helper cells in humoral immunity recognise different forms of chemically modified flagellin than do T cells in cellular immunity. Furthermore, Dennert<sup>8</sup> has shown that T-helper and T-killer cells are mutually exclusive under certain immunisation conditions. The reports of Dennert<sup>8</sup> and Liew and Parish<sup>7</sup> suggest that T helper cells may not be identical to T effector cells in cellular immunity. We have now used a rosette technique9 which distinguishes different degrees of antigen-binding, in combination with velocity sedimentation at unit gravity<sup>10</sup> to distinguish and separate T cells involved in the helper effect from T cells participating in cellular immunity reactions.

We have shown (work in preparation) that sheep red blood cells (SRBC) in complete Freund's adjuvant (CFA) injected C57BL/6 mice (Canadian Breeding Laboratories) induce both humoral and cellular immune reactions within 9 d after immunisation. For both of these responses T cells are necessary: T-helper cells trigger B cells for antibody synthesis<sup>11</sup>; T cells in cellular immunity are involved in delayed hypersensitivity (DHR) and in vitro cytotoxicity (our work in preparation). This system was therefore useful for investigating the relationship between T cells in humoral and cellular immunity in the same experimental animals and within the same lymphoid organ.

DHR and helper cell activity were assayed by adoptive transfer systems as reported previously (our work in preparation). To detect DHR activity, immune cells were injected with 5×107 SRBC intradermally into one footpad of normal animals. The other footpad received SRBC alone. The percentage in footpad volume after challenge was proportional to the number of immune cells injected. The DHR activity of SRBC immune cells was antigen-specific, sensitive to anti-θ serum plus complement, but insensitive to anti- $\theta$  serum alone (our work in preparation).

To assay for helper cell activity, immune cells and 2×108 SRBC were injected with or without  $2 \times 10^7$  bone marrow cells into lethally irradiated recipients and the number of 19S plaqueforming cells (PFC) per spleen was determined 8 d later. An increase in the number of splenic PFC when an immune cell population was injected with bone marrow cells indicated helper cell activity in that population.

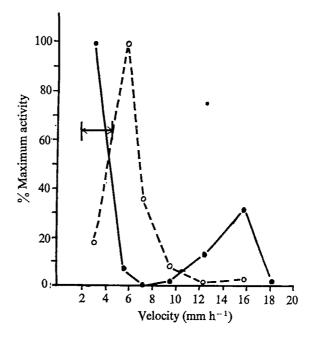

Fig. 1 Sedimentation velocity profiles of 19S helper cells and DHR effector cells from immune lymph nodes. C57BL/6 mice received an intradermal injection of 5×107 SRBC in CFA in the footpad. After 9 d, lymph node cells were removed, and subjected to rosette formation and sedimented with azide present. To assay for DHR, each fraction was injected with SRBC into the footpad of normal animals and the percentage increase in footpad volume was determined after 18 h. Footpad volume was measured by the deflection observed when the mouse foot was immersed in mercury on a Mettler 1600 balance to a mark made immediately distal to the lateral malleolus as described previously (our work in preparation). Three readings were made on each footpad and averaged. The difference in readings before and after skin testing was proportional to the increase in footpad volume. Percentage increase in footpad volume was calculated by dividing the difference by the original reading and multiplying by 100%. The relative activity was determined from a dose-response curve obtained with unfractionated immune cell1 (our work in preparation). To assay for helper cell activity, each fraction with 2 × 108 SRBC was injected either alone or with 2×107 normal bone marrow cells into syngeneic irradiated (750 r.) mice. 198 PFC per spleen were assayed 8 d later. Helper cell activity was calculated by subtracting the number of splenic PFC in mice injected with that fraction alone from that of the fraction plus bone marrow cells. O, 198 helper cell activity; , DHR activity. The velocity range of small lymphocytes ( $\longleftrightarrow$ ) has been indicated for convenience.

19S helper cells sedimented as medium lymphocytes at 5-7 mm h<sup>-1</sup> (Fig. 1). DHR effector cells sedimented over a wider range of velocities (3-7 mm h<sup>-1</sup>), indicating the presence of both small and medium lymphocytes. When immune cells were subjected to rosette formation before sedimenting in the presence of sodium azide (to stabilise T rosettes9,13), rosettes sedimented at velocities greater than 6.5 mm h<sup>-1</sup>, as reported<sup>13</sup>. Rosette formation, however, had no effect on the sedimentation velocity of 19S helper cells (Fig. 1). DHR activity remained in the nonrosette forming small lymphocyte region (3 mm h<sup>-1</sup>) (Fig. 1). Activity in the medium lymphocyte region, however, shifted to the higher velocity region (13-15 mm h<sup>-1</sup>), indicating that medium lymphocyte effector cells had formed rosettes. Without azide in the sedimentation medium T rosettes dissociated and medium lymphocyte effector cells sedimented as single cells (5-7 mm h<sup>-1</sup>). The calculated number of SRBC (bound to make a medium lymphocyte RFC sediment at  $13-15~\text{mm h}^{-1}$ ) is 8-10~SRBC (our work in preparation). Those antigen-binding properties are characteristic of T-type RFC (ref. 9).

These results indicate that 19S helper cells in immune animals are distinct from DHR effector cells. The latter were of two types: (a) non-rosette forming small lymphocytes and (b) medium lymphocyte T-type RFC. We have also found that SRBCspecific effector cells in in vitro cytotoxicity against sheep fibroblasts have the same size, antigen-binding properties, density

and sensitivity to anti-θ serum plus complement as DHR effector cells. These findings indicate that under the conditions of rosette formation used in the present study, 19S helper cells were distinct from T effector cells in cellular immunity.

Since the helper cell assay takes 8 d while the DHR and in vitro cytotoxicity assays take only 24 h, maturation of T helper precursor cells to T helper cells could occur. These experiments, however, strongly suggest that helper cells (or precursors) and T effector cells in cellular immunity are two different cells.

Recently, subsets of T cells with specific functions have been described. Cantor and Asofsky14 have shown that two T cells with different anatomical distribution and sensitive to antilymphocyte serum synergise in the graft-versus-host reaction. Bach et al.15 demonstrated that T cells involved in the mixed lymphocyte reaction are distinct from cytotoxic T cells. The distinction between 19S T-helper cells and T-effector cells in cellular immunity in the present study suggests a further division in T-cell subsets which is characterised in part by different abilities to bind antigen.

#### Cell-mediated immunity to Epstein-Barr virus and a blocking factor in patients with infectious mononucleosis

ALTHOUGH the humoral immune response to Epstein-Barr virus (EBV) in infectious mononucleosis (IM) has been studied extensively1,2, little is known about cell-mediated immunity (CMI) to EBV in the disease. We describe here the status of CMI to EBV, and the presence of a blocking factor which can abrogate leukocyte migration inhibition, in patients with IM.

Serum antibody to EBV-capsid antigen in normal adults and patients with IM were measured by indirect immunofluorescence<sup>3</sup>, using SH-RP cells<sup>4</sup> previously irradiated with ultraviolet light to enhance virus capsid antigen5. The results are shown in Tables 1 and 2.

Leukocyte migration inhibition was performed by employing 20 µl capillary tubes (Drummond Scientific Co., USA) as described earlier<sup>6</sup>. Peripheral leukocytes from each individual were washed four times in Hanks' balanced salt solution and then adjusted to  $3\times10^{-7}$  cells ml<sup>-1</sup> in Eagle's basal medium (Grand Island Biological, USA) with 10% heat-inactivated foetal bovine serum (BioCult, UK). The capillaries were filled with the cell suspension, sealed at one end and centrifuged at 950g for 5 min. These were cut at the cell-medium interface and immersed in the medium to which had been added an EBV-antigen preparation from P3HR-1 cell lysate<sup>6</sup>. The final concentration of the EBV-antigen preparation in the medium was 1:5. A minimum of eight replicate cultures was set up for each sample. Similarly, control cultures were set up in medium without EBV-antigen preparation. The cultures were incubated at 37° C in a humidified atmosphere of 5% carbon dioxide for 16 h.

The extent of leukocyte migration was determined by multiplying the greatest diameter of the area of cell migration by its perpendicular diameter measured by an ocular micrometer and the percentage inhibition was calculated as:

$$1 - \frac{\text{(mean extent of migration with antigen}}{\text{mean extent of migration without antigen}} \times 100$$

From the distribution of results (Table 1), we have considered a response positive when the percentage inhibition is 20% or greater, negative if smaller than 15% and equivocal if in between.

To test whether the effects of the EBV-antigen preparation on leukocyte migration could be abrogated by serum, sera from normal individuals (which had been stored at  $-20^{\circ}$  C for up to 8 weeks) and from subjects (cases 1, 2 and 3) at the acute and the convalescent phase of IM (fresh sera) were used. One ml of serum at various concentrations was mixed with an equal amount of the EBV-antigen preparation. The mixture was incubated at 37° C for 30 min. Leukocyte migration inhibition was carried out as described, using as test cells peripheral leukocytes (from a normal adult, case 7) known to have their migration inhibited by the EBV-antigen preparation in the presence of foetal bovine serum alone. The final concentration of EBV preparation in the serum-antigen mixture used in the medium was 1:5. EBV-antigen preparation and serum put up separately at the same concentration in the medium were used as controls. The results of these experiments are listed in Table 2.

In addition, the acute sera (stored at  $-20^{\circ}$  C for 14 d) and the freshly collected convalescent sera from cases 1, 2 and 3 were used to abrogate the effect of EBV-antigen preparation on leukocyte migration using autologous and heterologous leukocytes collected at the convalescent phase of IM. The results of these experiments showed that acute and convalescent sera from all three cases blocked the EBV-induced migration inhibition of autologous and heterologous leukocytes. In addition, the blocking effect observed decreased with increasing dilution of serum. Leukocytes and sera from cases 4 and 5 (Table 1) were used in a similar experiment, in which the antigen specificity of the blocking effect was indicated, using Escherichia coli as the irrelevant antigen (Table 3).

Acute sera from cases 1 and 4 were fractionated in a Sephadex G-200 column (2.5×100 cm, Pharmacia, Uppsala) at a flow rate of 20 mlh<sup>-1</sup>. The IgG and IgM fractions were collected and examined at 28 nm in a Beckman spectrophotometer.

Immunodiffusion of these fractions against standard rabbit anti-human IgG and anti-human IgM (Behringwerke,) in 0.8% agarose (Seakem Agarose, Marine Colloids Inc., USA) buffered at pH 7.6 showed that the IgG fraction reacted with the antihuman IgG but not with anti-human IgM standard serum. Similarly, the IgM fraction reacted with anti-human IgM standard serum only. Immunofluorescent testing showed that both fractions contained antibodies to the capsid antigen of EBV. Blocking activity to the EBV antigen preparation was carried out as described and was detected only in the IgG fraction.

CMI is important in defence against infection with most viruses, including oncogenic viruses8,9. As well as causing IM, EBV is a potential oncogenic virus in man because of its ability to transform human haematopoietic cells in vitro4.10, its ability to cause lymphomas in non-human primates11,12 and its association with at least two types of human tumour, Burkitt's lymphoma<sup>13</sup>, and nasopharyngeal carcinoma<sup>14</sup>.

We have shown that CMI to EBV was not detected in vitro in circulating leukocytes in the acute phase of IM (Table 1), but was found in circulating leukocytes of normal adults who had antibody to EBV and patients convalescent from IM. In

||Indicates abrogation of expected leukocyte migration inhibition.

addition, a blocking factor specific to EBV was found in the acute and convalescent sera of these patients (Tables 2 and 3).

Haider et al.15 have reported that in vivo CMI to tuberculin was apparently depressed in patients with acute IM. The absence of CMI to EBV in circulating leukocytes in the acute phase of the disease in the present study still allows the possibility that leukocytes mediating CMI to EBV are active outside the circulation. The development of CMI to EBV at the convalescent phase, however, as detected by leukocyte migration inhibition in the absence of autologous serum, suggests that a transient impairment of CMI function might have occurred.

It is not certain whether the blocking factor detected is part of normal negative feedback mechanisms involved in the immunity to virus infections, or whether it has an important role in the differential pathogenesis of diseases caused by EBV. The nature and the in vivo halflife of this blocking factor are unknown although we have shown that it was in the IgG fraction. Our experiments also indicate that it is not related to the EBV-capsid antibody, nor the Paul-Bunnell heterophil antibodies, as it is absent in normal sera with high level of EBVcapsid antibody (cases 7 and 10) and present in convalescent sera with no Paul-Bunnell heterophil antibodies. This could mean that the capsid antigen of EBV is not the antigen involved in the initiation of leukocyte migration inhibition, but as yet we have no direct evidence on this point.

Dameshek<sup>16</sup> has proposed that infectious mononucleosis, a benign lymphoproliferative illness, is a form of 'self-limiting' malignancy. It is plausible that CMI to EBV detected in these individuals is responsible for this 'self-limiting' expression. Considering the strong association of EBV with Burkitt's lymphoma and nasopharyngeal carcinoma it is important that CMI to EBV and the blocking factor be investigated in patients with these diseases at remission and recurrence.

#### Reversible appearance of a specific chromosome which suppresses malignancy

MALIGNANT cell transformation is associated with the appearance of abnormal chromosome patterns1. The degree to which malignant potential is expressed by transformed cells seems to depend on the balance between specific chromosomes responsible for the expression or suppression of malignancy<sup>2</sup>. Sachs et al.2-4 have demonstrated a relationship between these chromosomes and both oncogenic activity and cell membrane characteristics in transformed and reverted cells. Benedict et al.5, identified specific chromosomes associated with either expression or suppression of malignancy in hamster fibrosarcoma cells; tumorigenicity in different clones was related to the balance of these chromosomes.

We examined the genetic constitution of an established tumour line, and the chromosome alterations which may develop, by karyotypic analysis of 122 metaphases in cells from cultures and tumour nodules. Table 1 shows that prolonged maintenance of MC-42 fibrosarcoma cells in tissue culture has no significant effect on the modal number of chromosomes, when compared with the number in cells from serially-transplanted tumours. Injecting these cultured cells into syngeneic hosts resulted in a slight decrease in the modal number of chromosomes, irrespective of the duration of in vivo propagation. In all cases, chromosome banding revealed a complete complement of normal mouse chromosomes (Fig. 1a) in both cultured and serially-transplanted tumour cells. Eleven to sixteen subtelocentric, submetacentric and metacentric marker chromosomes, were also present; the cells inconsistently gained normal mouse chromosomes, as well as a long telocentric chromosome (Figs 1 and 2).

The only consistent genetic alteration associated with the culturing of MC-42 cells appeared in the marker chromosome pattern which is characteristic of this tumour line (Figs 1 and 2). The eighth marker chromosome (M<sub>8</sub>) showed specific variations between cells from tumour nodules and those from cultures. All cells from subcutaneous tumours contained only one M8 chromosome. When the tumour was transferred to tissue culture, however, cells with two M<sub>8</sub> chromosomes evolved,

first appearing (1 of 16 cells) in the 6th week of tissue culture propagation (Table 1). Four weeks later the proportion increased to 36% (4 of 11), and to 50% (11 of 22) after 12 and 17 weeks. Thereafter, the ratio of cells with one M<sub>8</sub> to those with two remained 1:1, regardless of the duration for which the cells had been cultured (not shown in Table 1). None of the seven other groups of marker chromosomes observed in MC-42 tumour cells showed any consistent variation associated with in vitro propagation (Figs 1 and 2).

Chromosome banding patterns: a, Normal C3H/HeJ mouse cells. b, Marker chromosomes from a serially-transplanted tumour. Note the eighth marker (M<sub>8</sub>); all cells from growing MC-42 tumours contain only one M<sub>8</sub> chromosome. c, Marker chromosomes from a cultured tumour cell containing one M<sub>8</sub> chromosome. d, Markers from a cultured tumour cell containing two M<sub>8</sub>. The tumour studied, a methylcholanthrene-induced fibrosarcoma (MC-42), had been propagated by serial transplantation in C3H/HeJ mice and had never been maintained in culture. The growth and immunogenicity of this tumour line have been described previously<sup>6,7</sup>. All tumours in this study were produced by subcutaneous inoculation of 20,000 viable cells (trypan blue exclusion) in McCoy's medium. Cultured cells were maintained in McCoy's 5a medium with 13% foetal calf serum, supplemented with penicillin, streptomycin and HEPES buffer. Cells were incubated in colchicine for 4 h, treated with trypsin and incubated in 1% sodium citrate for 20 min. They were then exposed to a fixative solution (acetic acid:methanol, 1:3) resuspended in 75% acetic acid and prepared for staining with 2% aceto-orcein. The method of trypsin/Giemsa R66 banding8 of chromosomes was used.

Tissue culture clones composed entirely of cells having either one or two M<sub>8</sub> marker chromosomes were grown by seeding cells from mixed cultures on to glass chips in Leighton tubes. Mass cultures containing equal proportions of cells with one and two  $M_8$  consistently produced a significantly greater number of clones of the one M8 variety. Multiple samples from clones, taken at periodic intervals, showed complete homogeneity with respect to either the single or duplicate M<sub>8</sub> pattern; no clones older than 6 weeks were used. When cloned cells having two M<sub>8</sub> were reimplanted into syngeneic hosts, the resulting tumour nodules were composed only of cells with one M<sub>8</sub> chromosome (Fig. 2). Inoculations of cloned cells having one M<sub>8</sub>, as well as inoculations of mass cultures, similarly produced tumours containing only cells with one M8 chromosome in every case. Cells with the duplicate M<sub>8</sub> pattern did not appear in vivo, irrespective of the age of the cultures

inoculated, the size of the tumour nodule examined, or the duration of in vivo growth. When cells from various (mass) cultures were reimplanted into syngeneic hosts, the frequency of tumour formation was lower if the inoculum contained a greater proportion of cells with two  $M_8$  chromosomes (see Table 1). No other consistent alterations in chromosomes were observed when cloned cells were injected into mice, although an occasional gain of markers  $M_{4a}$  or  $M_6$ , or loss of an  $M_2$  or  $M_5$ , was inconsistently noted.

Therefore, although cells with two  $M_8$  seem as viable as those with one  $M_8$  in vitro, the capacity for tumour growth is expressed only by those which have lost the second  $M_8$ .

Lymphocytes from mice bearing serially-transplanted tumours (all containing one  $M_8$ ), compared with those from mice bearing tumours (of equal size) which had been produced by inoculating (9 week) mass cultured cells, are more cytotoxic to tumour cells in each of the four target cell groups (Fig. 3). This difference was not affected by the addition of serum from mice with the tumours. On the other hand, target cells were more efficiently lysed if they had been maintained (9 weeks) in tissue culture. Cells from clones with one  $M_8$  were destroyed as efficiently as those from mass cultures. In contrast, the cytotoxic effect of sensitised lymphocytes was significantly less when target cells with two  $M_8$  chromosomes were used.

Fig. 2 Marker chromosome patterns: a, Tumour cell from a 10 week old mass culture. b, Cell from a tumour produced by injecting 20,000 (mass) cultured cells into a C3H/HeJ mouse. All cells in such tumours contain only one M<sub>8</sub> chromosome. c, Tissue culture clone (c1-7) containing only cells with two M<sub>8</sub>. d, Tumour nodule grown by injecting cells from the cultured clone c1-7 (shown in c). e, Tissue culture clone (c1-2) containing only cells with one M<sub>8</sub>. f, Tumour produced by subcutaneous inoculation of cells from clone c1-2 (shown in e).

The decreased ability of mass cultures of tumour cells containing both cells with one and two  $M_8$  to sensitise lymphocytes, together with the significantly lower cytotoxicity of target cells containing two  $M_8$ , may reflect the failure of cells with two  $M_8$  to express their tumour-associated antigens. The lower cytotoxicity does not seem to be directly related to the culturing process, as cells from mass cultures and from clones with one  $M_8$  were more efficiently lysed than cells from serially-transplanted tumours.

Giemsa banding of chromosomes (Fig. 1) shows that the M<sub>8</sub> has no bands on the short arms, suggesting that this portion of the chromosome may be from the normal mouse chromosome 19. The centromere is heavily stained and the long arms contain three prominent, moderately-stained bands in the mid-region, indicating that this portion may be an unaltered number 7 chromosome. Karyotypic studies of cells containing two M<sub>8</sub> consistently suggest that the M<sub>8</sub> is derived from a deleted number 19 chromosome, translocated on to a number 7. All MC-42 cells contain a complete complement of normal chromosomes together with an inconsistent number of additional chromosomes.

Multinucleated cells were present in all cultures before the duplicate M<sub>8</sub> pattern occurred. None of the cells displayed asynchronous DNA synthesis (which might indicate cell fusion) after exposure to <sup>3</sup>H-thymidine for 5 h. This suggests that multinucleation, chromosome ploidy and the evolution of MC-42 cells with two M<sub>8</sub> chromosomes may be the result of mitotic abnormalities, rather than of cell fusion.

Our data, therefore, show a strong association between the appearance of a second M<sub>8</sub> marker chromosome in MC-42 fibrosarcoma cells and the suppression of malignant characteristics. Sachs et al.1 have found that the in vitro propagation of polyoma virus-transformed cells may favour the appearance of chromosomes which suppress malignant characteristics. By fusing highly malignant ascites tumour cells with non-malignant cells, Harris et al.10 produced both tumour cells in which malignancy and the expression of histocompatibility antigens were suppressed; a loss of chromosomes from these hybrid cells was associated with recovery of the ability to grow progressively in vivo. These reports are consistent with our data, in that cultures of the MC-42 fibrosarcoma developed variants which appeared less tumorigenic and less immunogenic, and which lost a chromosome when malignancy was expressed. The MC-42 tumour line, however, contains the only example of a suppressor chromosome (the second M<sub>8</sub>) which is paired with a morphologically identical chromosome (M<sub>8</sub>) that alone has no apparent direct influence on the suppression of malignancy. In polyoma virus-transformed hamster cells11, where the chromosome group which suppresses malignancy has been identified, there seems to be a direct relationship between the number of suppressor

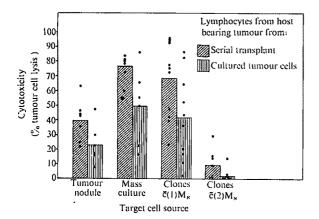

Fig. 3 Ability of lymphocytes from mice administered seriallytransplanted or (mass) cultured tumour cells to lyse target cells from either serially-transplanted tumours, mass cultures, clones of cells with one M<sub>8</sub> or those with two M<sub>8</sub>. Lymphocytes were purified (Ficoll-hypaque separation) from the spleens of animals bearing palpable tumours and the cytotoxicity assay was performed according to the method described previously Target cells were plated in Falcon 3040 Microtest II wells and the cells directly counted 24 h later. Target cells were then exposed to lymphocytes for 2 d, washed with saline and stained with crystal violet for final counting.

chromosomes and the degree of suppression. Furthermore, a chromosome group responsible for the expression of malignancy has been identified in that tumour, the number of such chromosomes in cells of any clone being proportional to the degree of malignancy of that clone. When cells from clones of suppressed polyoma virus-transformed cells are reimplanted into syngeneic hosts, the tumours produced contain fewer suppressor chromosomes and more chromosomes for the expression of malignancy. Careful examination of MC-42 tumour cells failed to demonstrate a specific chromosome group responsible for the expression of malignancy.

The study was supported in part by the Harvard Medical School, Department of Surgery, and in part by the New York State Kidney Disease and Birth Defects Institutes. #### Isolation of Bacillus anthracis from an aborted bovine foetus

We report here the presence of virulent anthrax bacilli in aborted tissues. This is significant in that it suggests that the foetus becomes infected during the bacteraemia/pyrexia phase of the dam, and that the bacilli continue to multiply in and cause the death of the foetus despite the recovery with treatment in the parent cow. Since abortion may be a sequel to the infection in pregnant animals which survive, the products of such abortions must be regarded as potential vectors of anthrax both for man and other animals.

In Spring 1974 two cows died within 24 h of each other and anthrax was confirmed in each case. Control measures included the immediate vaccination of the remainder of the herd with a proprietary spore vaccine. Anthrax Spore Vaccine (Living), (Wellcome). The following day a cow became ill, having a rectal temperature which rose to 41.1° C. Antibiotic therapy was instituted and the animal recovered within 48 h. But 13 d after vaccination this cow aborted a foetus and placenta within an isolation box. In keeping with the Brucellosis Incentives Scheme rules, serum, milk and the products of abortion were forwarded to the local Veterinary Investigation Centre. The gestational age of the foetus was determined as 120 d. but apart from softening of the liver no gross pathological changes were seen in either the foetus or the placenta which might have indicated the possible presence of anthrax. Examination of smears prepared from foetal stomach contents and placental cotyledons revealed chains of encapsulated bacilli; overnight cultures prepared from similar sites were suggestive of Bacillus anthracis and material was forwarded to the Central Veterinary Laboratory, Weybridge, for identification.

Two guinea pigs inoculated subcutaneously with 1 ml of a saline suspension of the culture ( $\sim 1 \times 10^6$  organisms) and 1/100 dilution of a saline suspension ( $\sim 1 \times 10^4$  organisms) respectively died within 48 h. On post mortem examination hyperaemia associated with oedema, characteristic of anthrax, was observed and Bacillus anthracis was isolated in pure culture from blood and oedema. Anthrax was confirmed by the presence of encapsulated bacilli in guinea pig blood smears fixed and stained with 1% aqueous solution of polychrome methylene blue. The vaccine strain is seldom lethal for guineapigs and is not encapsulated if present in the blood of inoculated guinea pigs1.

Two vaginal swabs and a faeces sample, taken from the cow 3 d after abortion, did not yield anthrax bacilli on bacteriological examination at the Central Veterinary Laboratory.

#### **Evolution of the Tasman Sea**

WE do not accept Hayes and Ringis" "conclusive evidence" that the central Tasman Sea evolved by symmetrical spreading from a median north-west trending ridge between 80-60 Myr ago, for several reasons.

First, their 'ridge' and 'fracture zones', which are mantled by sediments, have no bathymetric expression.

Second, they ignore the only conspicuous topographic features within the limits of their magnetic anomaly

pattern. These are the seamounts and knolls respectively north and southwest of Gascovne Guyot. Both trends are oblique to their magnetic grain and fracture direction (Fig. 1).

Third, their seismic data are said to "reveal a distinct basement ridge" blanketed by acoustically transparent sediments which "thin subtly near the crest of the buried ridge". We contend that only their profile X could be described thus, and its "axial rift" is equivocal.

Fourth, they ignore an elongate area of thin sediments' which is coaxial

with the knolls south-west of Gascoyne Guyot (Fig. 1), but which is unrelated spatially to the 'ridge' and 'fracture zones'.

Fifth, they are prepared to consider that spreading "was much slower in the northern area than in the southern area", but this is contrary to the anomaly spacings, and therefore to the identifications, which they adopt.

Sixth, they maintain that limited subduction along the Tasman margin of Australia 80-60 Myr ago cannot be excluded. Yet no rocks of orogenic character on this margin are younger than Triassic and all are related to a Palaeozoic-Mesozoic tectonic regime expressed in a north-north-west continental grain which is cut obliquely by the present margin. The only post-Triassic volcanics on this margin are non-orogenic and are less than 55 Myr old3.

Seventh, their pre-Tasman reconstruction of Australia/Antartica and the New Zealand Plateau involves a misfit (gaps plus overlaps) which is equivalent to half the area of the latter. Furthermore, they reduce the potential misfit considerably by eliminating the Alpine Fault, although most studies indicate that major movement on it occurred during the early Cretaceous'.

Eighth, their hypothesis cannot account for the NE-SW orientation (oblique to the trends of their 'ridge' and 'fracture zone'; Fig. 1) of the dominant topographic elements of the Tasman margin, centred on Sydney.

Finally, their hypothesis cannot account for recurrent Cainozoic basaltic volcanism on Australia's Tasman margin3 which entirely post-dates, their postulated termination of Tasman dilation 60 Myr ago.

A more extensive discussion of these points can be obtained from us.

#### Red Sea spreading

GIRDLER and Styles1 cite geological evidence2 from the Gulf of Suez area favouring the idea that a Carboniferous Red Sea depression existed. Various views have been put forward concerning the age of the Suez rift structures3-6. Some authorities believe block faulting and rifting does not predate Oligocene6; others have isopached a post-crystalline Basement Complex to pre-Permian linear trough7; and some believe in a Mesozoic trough3.

Even if definite proof were available publicly of a Carboniferous trough this would not necessarily prove that a trough of this age existed in the Red Sea area, because the Suez structures are part of a failed arm system8,9; the Red Sea structures are part of an active spreading ridge system and the Aqaba-Dead Sea structures part of an active transform system. As such the three arms have had interlinked but separate geological histories8.

There is clear evidence in the southern Red Sea area, however, of major rifting before the Early and Medial Eocene proposed by Girdler and Styles<sup>1</sup>. A pre-Mesozoic (?pre-mid Jurassic) trough some 500 km long; up to 150 km wide and containing up to 7.5 km of sediments in the Mandera region of Somalia extends from coastal Tanzania to Afar<sup>10</sup>.

This trough as roughly mapped intersects the Cainozoic RRR Afar junction. Some implications are: first, that the Somalia trough may be part of an older failed rrr 'Karroo' junction, with the other failed arms buried beneath the sediments of the southern Red Sea and Gulf of Aden; second, the evolution of the Cainozoic Nubian - Somalian -Arabian plate relationships must be viewed with this in mind; and third, that the Mesozoic African plate may have rotated anticlockwise after the attempted 'Karroo' disruption (crustal thinning, necking, troughing and so on) so enabling the Cainozoic East African Rift to develop over the 'Karroo' mantle plume system.

DR GIRDLER AND MR STYLES REPLY-WHITEMAN'S views on the formation of the Red Sea are well known. He considers1 that "downwarping has been the major force in shaping the Red Sea depression" and he objects to any major crustal separation with the evolution of oceanic crust.

His objection to a Carboniferous Red Sea Depression is puzzling since in the literature he has been an advocate of this. In the summary of his paper Formation of Red Sea Depression he states "A depression existed in the northern part of the region in Carboniferous times . . . " and on p. 237 we find "In the writer's (Whiteman's) view the Red Sea has been an area of subsidence for a large part of post-Cambrian time." We respect that this is a view held by some geologists and mentioned it in passing2. We were careful to put a question mark<sup>2</sup> in our Fig. 7 and it should be clear from our Figs 5 and 6 that it is unimportant to our arguments.

We have been interested in the postulated 'ancestral pre-Jurassic trough' running from the Southern Red Sea across the horn of Africa to intersect the Tanzania coast<sup>3,4</sup> but at the moment it seems unrelated in time and space to the seafloor spreading discussed.

#### Solubility of oxygen-nitrogen mixture in water

Maharajh and Walkley1 have reported that mixtures of gases containing oxygen do not behave independently when they are dissolved in water, and as a consequence Henry's law may be

deviated from by as much as 30%. Liss and Slater<sup>2</sup> found that the amount of oxygen dissolved in water from an air mixture at 25° C and atmospheric pressure obeyed Henry's law within their experimental limits (4%). Wilson<sup>3</sup> has reviewed some of the various measurements of oxygen solubility in water at different partial pressures and showed that Henry's law is generally accurate in predicting the amount of gas dissolved to within a few per cent. A thermodynamic analysis4 of Maharajh and Walkley's results showed that the large negative deviation from Henry's law (maximum at about a 1:1 nitrogen to oxygen ratio) leads to an absurd value for the Henry's law constant.

There have been many reports of the solubility of gas mixtures in water, and in most cases these may be shown to be in agreement with Henry's law. Glasstone5, using Winkler's data6, has demonstrated that the solubilities of oxygen, nitrogen and argon each multiplied by their atmospheric partial pressure may be used to calculate the solubility of air in water to within 1%. We have calculated the hypothetical solubility of an air mixture<sup>7</sup> of oxygen, nitrogen, argon and carbon dioxide, using smoothed literature values for the solubilities of the individual gases8,8. The resulting solubility is 4% higher than that reported by Winkler<sup>6</sup>. Behnke<sup>10</sup> measured the solubility of a mixture of argon and nitrogen in water, and his value is 5% above the value calculated from Henry's law and using the recommended literature values for the solubilities of argon and nitrogen8.

We have measured the solubilities in water of nitrogen, oxygen, and a mixture of oxygen (49.5 mol %) and nitrogen (50.5 mol %) at atmospheric pressure and 25° C. The procedure used for the solubility measurements has been desscribed previously11, and the precision of these measurements is  $\pm 1\%$ . The experimentally determined solubilities expressed as mole fractions (at one atmosphere partial pressure of gas) are given in Table 1.

The value predicted for the mixed gases on basis of Henry's law is 0.1711 × 10<sup>-4</sup>, which is 3% lower than the experimental value (average,  $0.1770 \times 10^{-4}$ ). These results are conclusive evidence that Henry's law is not deviated from

Table 1 Solubilities as mole fractions  $\times$  104. Literature<sup>8</sup> values are given in parentheses

Little	o mado uno gini	m paroneneses

by as much as Maharajh and Walkley claim. It appears that if anything, the solubility of oxygen in water is enhanced to a small extent by the presence of nitrogen rather than lowered by it.

We have had considerable experience in determining gas solubilities by gas chromatography (the technique Maharajh and Walkley used). It is extremely difficult to attain precisions better than 3% by this method. Indeed, in our judgment, the precision of other workers may actually be as poor as  $\pm 10\%$ . We suggest that the results reported by Maharajh and Walkley are due to inherent difficulties in the gas chromatographic approach.

#### Redshift during Pioneer-6 solar occultation unexplained or predicted

THE recent detailed analysis1,2 of Pioneer-6 data<sup>3</sup> demonstrated, under controlled conditions, the existence of the redshift effect which we predicted<sup>4-6</sup>. The explanations proposed by us for certain anomalous redshifts were based on the simple fact, that a moving inhomogeneous medium results in frequency shift and line broadening4.5. (But there is no close correlation between line broadening and frequency shift.) Therefore the search for highly specific or hypothetical explanations for redshift effects, observed on or around the Sun, seems to be unjustified.

The Pioneer-6 frequency residuals could be reproduced well (Fig. 1), without any effort to reach a better agreement between

measured points and theoretical curve. In computing the theoretical curve, the method described in refs 4-6 was used. In the given range of heliocentric distances the particle density was taken proportional to  $r^{-3}$  and the velocity of the medium was decreased in the vicinity of the Sun. Unfortunately the original data of Pioneer-6 were not available to us, so we were compelled to use the data

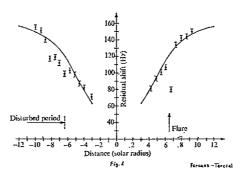

Fig. 1 Residual frequency shift1 and computed curve, corresponding to the moving medium around the Sun, as a function of the minimum distance of Pioneer-6 2,292 MHz radio signal to the centre of the Sun.

published in refs 1-3. From these, however, one cannot establish exactly the zero-line of frequency residuals. Therefore the measured points and the theoretical curve were tied together on the basis of the measured data, referring to  $r = 5 R_{\odot}$ , known satisfactorily from the Taurus A experiments<sup>4</sup>.

Furthermore, the overall picture of solar activity exhibits a correlation with deviations from the theoretical curve, and the effect of enhanced solar activity appears also in the asymmetric bandwidth pattern (ref. 2, Fig. 1b).

With special respect to the opportunities afforded by the space shuttle, it would be expedient in the future to measure accurately the solar disk and corona (the latter by occultational methods) for frequency shift and line broadening in different regions of the electromagnetic spectrum.

#### **Spatial distribution** of cometary outbursts

PATASHNICK et al.1, in reproducing figures of the position of comets at the times of cometary outbursts from the papers of Pittich2,3, have omitted the outbursts of comet P/Schwassmann-Wachmann (1) (1925 II) which have been observed regularly since 1927 (ref. 2). Richter4.5 concluded that the outbursts of the latter were essentially similar to those of 12 other comets. The omission of these data is therefore unjustified.

Figure 1 is a histogram of the number of observed cometary outbursts  $N_0$  in the interval R to R+0.25 AU as a function of R, the distance between the comet and the Sun at the time of outburst. Three regions are apparent:

- (a) R < 1 AU. The increase of  $N_0$  with Ris simply a reflection of the distribution of cometary perihelion distances8.
- (b) 1 < R < 5.5 AU. A minimum deviation fit gives

$$N_0 = (24 \pm 4) R^{-(2.2+0.1)}$$

Contrary to ref. 1, it is thought that here  $N_0(R)$  is determined chiefly by observational selection, the ratio between detected and undetected outbursts decreasing as the Earth-comet distance increases.

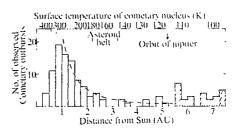

Fig. 1 Number of observed cometary outbursts as a function of distance from the Sun R. Hatched regions, Comet P/Schwassmann-Wachmann (1); White regions, other comets; dashed curve, minimum deviation fit to the data in 1 < R < 5.5 AU region.

(c) R > 5.5 AU. These data originate in toto from comet P/Schwassmann-Wachmann (1) containing outbursts from two complete orbits. There is no clear variation of  $N_0$  with R. It is therefore concluded that the probability of outburst occurrence for the other comets is also independent of R, at least for R < 7.5AU, and similarly independent of temperature for  $T > 115 \,\mathrm{K}$  (the surface temperature of the cometary nucleus is shown as the upper abscissa in Fig. 1, this being calculated assuming that the cometary nucleus has an albedo of 0.6 and is a rapidly rotating sphere). This rules out the three temperature-dependent theories of outburst production—Whitney? requiring T > 130 K to produce pockets of vaporised methane, Donn and Urey8 requiring T > 148 K to produce the explosive NH<sub>4</sub>N<sub>3</sub> and Patashnick et al.<sup>1</sup>

needing T > 140 K for the phase transition between amorphous and cubic ice. This latter theory also requires amorphous ice to have the suspiciously high density of 2.3 g m<sup>-3</sup>, implying an O-O distance of ~ 2.0 Å compared with the more normal 2.8 Å. None of these can account for the outbursts of P/Schwassmann-Wachmann (1).

Three theories remain—tidal disruption by Jupiter, asteroidal collision and collision with boulders9 (mass~108 g). Pittich<sup>2</sup> has ruled out the first two, leaving only the boulders.

#### Changes in the latitude of the climatic zones of the Northern Hemisphere

In a discussion of the drought in the Sahelian Zone of Africa it has been suggested1 that the drought is associated with a shift of the climatic zones of the Northern Hemisphere towards the equator. An analysis by Lamb was quoted as evidence for this shift, but Lamb's analysis was mainly related to the

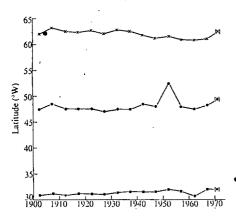

Fig. 1 Average latitudes of climatic zone parameters in the North Atlantic (whole year). Five year means except the last plot which is 1970-1973. ×, Subpolar flow; •, westerly maximum; , subtropical high.

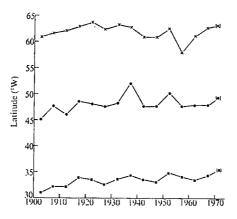

Fig. 2 Average latitudes of climatic zone parameters in the North Atlantic (summer). Five year means except the last plot which is 1970-37.  $\times$ , Subpolar flow; •, westerly maximum; , subtropical high.

subpolar pressure minimum, and the latitude of the subtropical pressure maximum would seem to be more relevant to the Sahelian zone.

Using values of sealevel pressure stored on magnetic tape in the form of a grid, the latitudes of the subpolar minimum of pressure, the subtropical maximum of pressure and the latitude of strongest westerly winds were calculated. Nonoverlapping periods of 5 yr from 1900 to date were used, both for the northern hemisphere and the North Atlantic region (10°W to 60°W). Figure 1 shows these three parameters for the Atlantic region for the whole year and Fig. 2 for the Atlantic for the summer (June, July and August).

The data for the whole year confirm Lamb's analysis in indicating a slight trend of the subpolar pressure minimum towards the equator but show no trend or even a slight one towards the pole for the maximum of the westerlies and the subtropical pressure maximum. The data for summer lead to broadly the same conclusion, except that the trend of the subtropical pressure maximum towards the pole is stronger. The results for the whole hemisphere are similar. What

## Matters arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in The originator of Nature. Matters Anising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

is particularly notable is the trend of all the parameters towards the pole for the whole year and for the summer over the past three 5 yr periods while the Sahelian rainfall has been decreasing. This makes the hypothesis that the present Sahelian drought is due to a shift of the climatic zones towards the equator scarcely tenable.

#### Role of arginase in the epidermis

THE article by Oka and Perry concerning the role of arginase in the mammary gland1 suggests an explanation for the high levels of this enzyme in the skin2,3. This tissue resembles mammary gland in that the remaining enzymes of the urea cycle seem to be absent.

A large body of work exists regarding the stimulation of epidermal proliferation as a result of wounding. Such stimulation is preceded by the induction of ornithine decarboxylase and the production of putrescine and spermidine under the influence of the epidermal growth factor 4.5. Thus, it seems possible that the function of arginase, at least in the epidermis, is to provide a reservoir of ornithine for the production of spermidine. This idea is consistent with the observations that cutaneous lesions associated with pathological proliferation of rete cells, such as psoriasis and the common wart2, or following experimental application of carcinogenic substances, show greatly increased arginase activity.

Of course it is possible, as Oka and Perry point out, that arginase may also be involved in the production of proline, although this seems less likely to be of significance in the epidermis than in the dermis.

# THEORE'

L.D. LANDAU (Deceased)

E.M. LIFSHITZ Institute for Physical Problems, Academy of Sciences of the USSR

This internationally renowned series written by two of the world's most outstanding physicists, the late Soviet academician and Nobel Prizewinner L.D. LANDAU, and fellow academician E.M. LIFSHITZ, is being published in its entirety by Pergamon Press."

# Independent opinion!

"The titles of the volumes in this series cover a vast range of topics; and there seems to be little in physics on which the authors are not very well informed.'

Nature

Volume 1: MECHANICS - (Now in its 2nd edition) "The entire book is a masterpiece of scientific writing. There is not a superfluous sentence and the authors know exactly where they are going . . . It is certain that this volume will be able to hold its own amongst more conventional texts in classical mechanics, as a scholarly and economic exposition of the subject.

Science Progress

ISBN 0 08 006466 8 h 174 pp 55 illus US\$9.50

Volume 2: THE CLASSICAL THEORY OF FIELDS (4th revised edition due May 1975)

"This is an excellent and readable volume. It is a valuable and unique addition to the literature of theoretical physics."

"The clarity of style, the conciseness of treatment, and the originality and variety of illustrative problems make this a book which can be highly recommended.' Proceedings of the Physical Society

ISBN 0 08 016019 0 h 386 pp 22 illus. Price not vet set

Volume 3: QUANTUM MECHANICS Non-relativistic Theory (Now in its 2nd edition)

"...throughout the five hundred large pages, the authors' discussion proceeds with the clarity and succinctness typical of the very best works on theoretical physics." Technology

ISPN 0 08 009101 6 h 632 pp 54 illus. US\$21.00

#### Volume 4: RELATIVISTIC QUANTUM THEORY -PART 1

"The treatment is very thorough, ... without being cluttered with matter irrelevant to practical calculation; it is careful without being pedantic; and it is well supplied with applications to experimental situations . . . the price seems high but the contents makes this excellent value."

**Physics Bulletin** ISBN 0 08 016025 5 h 392 pp 48 illus. US\$16.25

Volume 5: STATISTICAL PHYSICS: (Now in its 2nd edition)

"... stimulating reading, partly because of the clarity and compactness of some of the treatments put forward, and partly by reason of contrasts with texts on statistical mechanics and statistical thermodynamics better known to English scientists . . ! Other features attract attention since they do not always receive comparable mention in other textbooks."

ISBN 0 08 009103 2 h; 496 pp 71 illus. US\$15.00

"The remarkable nine-volume Course of Theoretical Physics . . . the clearness and accuracy of the authors' treatment of theoretical physics is well maintained."

Proceedings of the Physical Society

#### Volume 6: FLUID MECHANICS

"The ground covered includes ideal fluids, turbulence, boundary layers, conduction and diffusion, surface phenomena and sound. ... a valuable addition to any library covering the mechanics of fluids."

Science Progress

ISBN 0 08 009104 0 h 536 pp US\$17.50

Volume 7: THEORY OF ELASTICITY (Now in its 2nd

"I shall be surprised if this book does not come to be regarded as a masterpiece."

Journal of the Royal Institute of Physics (now the Physics Bulletin)

"... the book is well constructed, ably translated, and excellently produced."

Journal of the Royal Aeronautical Society ISBN 0 08 006465 5 h 176 pp 28 illus. US\$10.00

#### Volume 8: ELECTRODYNAMICS OF CONTINUOUS MEDIA

"Within the volume one finds everything expected of a textbook on classical electricity and magnetism, and a great deal more. It is quite certain that this book will remain unique and indispensable for many years to come."

Science Progress

"The volume on electrodynamics conveys a sense of mastery of the subject on the part of the authors which is truly astonishing. Nature

ISBN 0 08 009105 9 h 428 pp 45 illus. US\$1,6.50

The Series comprises nine volumes of which the first eight have already been published in Russian and translated into English. A number of these volumes are now available in their 2nd, 3rd or 4th revised editions and the entire series is now in the process of being thoroughly revised and updated by Professor Lifshitz and his colleagues. Volume 9 in the series, PHYSICAL KINETICS, is currently in preparation.

Please address all enquiries concerning the series and individual volumes in the series to the Marketing Department,

# TERSCIENCE

#### DRUGS AND BEHAVIOUR: A Primer in Neurophsychopharmacology

By Ernest L. Abel, Research Institute on Alcoholism, Buffalo. Considers cellular functioning, the functional organization of cells in the central nervous system, how drugs move from the sites of their administration to their cellular sites of action, and the transformations that occur during this movement.

October 1974

240 pages

£7.55

#### **BIOLOGICAL DIAGNOSIS OF BRAIN DISORDERS**

Edited by Samuel Bogoch, Foundation for Research of the Nervous System and the Dreyfus Medical Foundation.

(Based on the Fifth International Conferences on the Future of the

Brain Sciences, October 1972, New York.)
This volume brings together contributions of the foremost international researchers who have made significant direct approaches to the nervous system, both electrophysiologically and biochemically. The book points out areas which are already funtionally useful in devising new diagnoses and new therapies for brain disorders and selects those methods which appear to show early promise of useful clinical applications.

November 1974

408 pages

£12.15

Published by Spectrum Publications Inc., and distributed by John Wiley and Sons Ltd.

#### **CELL COMMUNICATION**

Edited by Rody P. Cox, New York University School of Medicine. Cell communication is the process whereby cells exchange information. This book reviews examples of cell interactions in several biological systems. (Wiley Series in the Dynamics of Cell Biology).

November 1974

272 pages

£11.90

#### CHROMOSOMES AND CANCER

Edited by James German, M.D., New York Blood Center.

Explores how various types of chromosome changes may be associated with cancer and how they may be important in the predisposition to and inception of cancer as well as in its progression and response to therapy. Includes reviews of the major areas of investigation since Theodor Beveri's 1914 work On The Problem Of The Origin Of Malignant Tumors. Authors are distinguished authorities who have developed hypotheses, devised original experiments, and made important observations or surveys in their areas of study. (The first volume in the Wiley Series: Chromosomes).

November 1974

774 pages

£17.40

#### METHODS OF BIOCHEMICAL ANALYSIS, Volume 22

Edited by David Glick, Stanford Research Institute.

Topics include chemical, physical, microbiological, and animal assays as well as basic techniques and instrumentation for the determination of enzymes, vitamins, hormones, lipids, carbohydrates, and proteins and their products. Well established methods are reviewed and promising new approaches are introduced.

December 1974

576 pages

£13.50

#### FAUNA OF THE USSR, DIPTERA, Volume 111, Mosquitos: **Family Culcidae**

By A. V. Gutsevich, A. S. Monchadskii and A. A. Shtakel'berg. Zoological Institute, USSR Academy of Sciences.

A description of the most important species of mosquitos occurring in the USSR. Introductory part containing data on morphology, biology, epidemology and distribution. Systematic part; keys to adults and larvae and illustrated descriptions, with the stress on characters of diagnostic value. (Translated from the Russian.)

September 1974

412 pages

Published by Israel Program for Scientific Translations Ltd., and distributed by John Wiley and Sons Ltd.

#### ANIMAL CELL CULTURE AND VIROLOGY

Edited by Robert J. Kuchler, Rutgers University.

Papers deal with the role animal cell culture has played in unfolding the details of the biochemistry of the replication of viruses. Brings together the disciplines of cell culture and virology because it is becoming increasingly clear that viral physiology is very closely linked to the physiology of the host cell infected by the virus. Provides background in the biology of cultured cells and current information on structure and composition of viruses. (Benchmark Papers in Microbiology.)

October 1974

480 pages

Published by Dowden, Hutchinson and Ross Inc., and distributed by John Wiley and Sons Ltd.

#### ADVANCES IN ENZYMOLOGY AND RELATED AREAS OF **MOLECULAR BIOLOGY, Volume 41**

Edited by Alton Meister, Cornell University Medical College.

Offers authoritative reviews of the progress in various branches of this expanding science. Authors have made significant contributions in each of the areas covered and emphasizes recent developments.

October 1974

372 pages

£11.35

#### **OBESE HUMANS AND RATS**

By Stanley Schachter, Columbia University and Judith Rodin, Yale University.

Examines the behavioral similarities of obese humans and animals with lesions in the ventromedial hypothalmic nuclei (VMH)-the presumed satiety center in the brain. Proposes a theoretical formulation to incorporate diverse findings on humans and animals, presents tests of the model on humans, and suggests tests for animals. (Complex Human Behaviour Series).

# reviews

# Pavlovian views in Soviet science

Biology and Neurophysiology of the Conditioned Reflex and its Role in Adaptive Behaviour. By P. K. Anokhin. Pp. xvi+574. (Cerebrovisceral and Behavioural Physiology and Conditioned Reflexes.) (Pergamon: Oxford and New York, June 1974.) £17.00.

Few historical figures command the attention of working scientists. Pavlov, however, remains important, not only for the obvious historical reason that he opened up a new and fruitful field of study, but for the eminently practical reason that many of his detailed findings and behavioural analyses are as valid today as when they were first formulated. Among western students of animal learning, interest in classical or Pavlovian conditioning is probably greater today than it has ever been: it has become increasingly clear that such conditioning is of wider scope and greater importance than has been suggested by the traditional American emphasis on instrumental learning and the law of effect.

It is interesting, therefore, to see how the Pavlovian tradition has fared in the Soviet Union, and one may welcome a major statement by one of Pavlov's students, even if blenching at the price one is asked to pay for it. Even more welcome might have been a statement by a psychologist of a younger generation, but it still seems that only those who sat at the feet of the master can hope to have their books translated into English. Can Soviet psychology really be so patriarchal, or is this a reflection on the policy of western publishers?

It must be said at the outset that this is not a book for casual browsing. It is very hard going. A major problem is that, as is here amply confirmed, Soviet and western students of conditioning have taken over quite different facets of Pavlov's work. Pavlov did two things: first, he studied the behavioural facts about the new conditional reflexes he had discovered by accident, and attempted to elucidate the laws governing their acquisition, extinction, generalisation, and so on; second, he attempted to infer the physiological

Ivan Pavlov-still the Soviet patriarch?

mechanisms responsible for these behavioural laws. Although Pavlov did not draw a sharp distinction between these tasks, it is important to recognise that they do indeed differ. Western behaviourists, at any rate, have followed the former programme of research; but in the Soviet Union, where the study of conditioning is described as the physiology of higher nervous activity, it is the latter interest that has prevailed.

Even if it is accepted that the eventual goal of psychology is to understand behaviour in terms of the functioning of the nervous system, it seems likely that this goal will be attained only after the establishment of valid behavioural laws, and the achievement of some insight into the general logic of the system which produces that behaviour. Although the neurophysiological knowledge which Anokhin can draw on is immeasurably more sophisticated than that available to Pavlov 50 years ago, it is not clear that this increase in knowledge has advanced our understanding of conditioning. Anokhin's use of neurophysiological evi-

dence, at any rate, is often distinctly peculiar. A good example is his discussion of the "accursed problem" (Pavlov's description) of inhibition. Behaviourally, the term inhibition is used in several ways: an inhibitory stimulus, for example, is one which signals the omission of the unconditioned stimulus; an inhibited response is one which does not occur in a situation in which it has occurred in the past. In neurophysiology, the term is used in a different set of ways, here most often to refer to the blocking of neural transmission ascribed to postsynaptic hyperpolarisation. Anokhin has no qualms about using this neurophysiological concept to dictate a number of psychological conclusions. Thus, since physiological inhibition "exists only so long as the excitation that gave rise to it exists," inhibitory conditioning can occur only in response to prior excitatory conditioning. Again, since physiological inhibition is a "purely local process" which "always remains at its point of origin," we can reject Pavlov's theory of inhibition which assumed that inhibitory stimuli

themselves acquired new, inhibitory properties, for that requires the assumption that inhibition is initially localised in sensory cortical areas, and would then have to be propagated to the cortical representation of the unconditioned reflex. Indeed, the fact that physiological inhibition does not irradiate over the cortex is used by Anokhin to establish an even stronger conclusion: since the effects of inhibitory conditioning to one stimulus do generalise to similar stimuli, such conditioning cannot, in fact, be inhibitory at all; its effects must be caused by the excitatory conditioning of an antagonistic motivational state.

Most western psychologists, I think, would agree that this type of argument was radically misconceived. What they will find worse, is the way Anokhin continually shifts back and forth between behavioural and physiological evidence, with no clear recognition of the difference between the nature of the evidence in the two cases. With some effort, one can discern the similarities between Anokhin's behavioural arguments and those familiar to western psychologists. Thus, Anokhin's general analysis stresses the importance of a feedback principle (the action acceptor), whereby discrepancies between behaviour and goal are registered and serve to initiate correcting action. Inhibitory learning is then said to arise when the organism detects an adverse discrepancy between the actual and expected outcome of a trial (as the omission of expected food), and this generates an aversive motivational state which suppresses the organised appetitive activity originally conditioned by the presentation of food. There is an obvious resemblance to the version of frustration theory proposed by Spence, Amsel and others, and Anokhin occasionally adduces behavioural evidence in support of his account, which is gratifyingly similar to that advanced in support of frustration theory. But this is Interspersed with neurophysiological evidence, and separated by chapters of neurophysiological analysis, the behavioural implications of which are at best obscure, and at worst patently nonexistent.

As its title suggests, the book is concerned not only with the analysis of conditioning and learning, but also with the biological significance of unconditioned reflexes, and the nature of adaptive systems. Occasional passages in these chapters ring true to a western ear, but it is hard to find many examples of sustained argument or of close interplay between data and theory. It seems depressingly insular to say so, but if there is anything for us to learn from Soviet psychology, it is not apparent from this book.

N. J. Mackintosh

#### Book of the moth

The World of Moths. By Michael Dickens and Eric Storey. Pp. 127. (Osprey: London, 1974.) £2.25.

In a world that contains over 100,000 species, authors who must restrict an introductory book to cover only 100 species have a difficult task. Although there may be a temptation to choose only British species, I am delighted to find that this small, unpretentious book makes those new to the subject, especially young people, immediately aware of what exists in the tropics. It dispels the illusion that moths are "dirty brown things" and although 'professionals' will argue that but a few families are represented, with emphasis only on hawk moths (30 species) and silk moths (39 species), I think this is a delightful 'starter's book' with a whole page of useful information devoted to each species illustrated. The coloured photographs are splendid and I am sure that, at its modest price, the book will be a favourite Christmas gift.

E. R. Laithwaite

# Radiation, ecology, and Soviet concern

Radioecology. Edited by V. M. Klechkovskii, G. G. Polikarpov, and R. M. Aleksakhin. (A Halsted Press Book.) Pp. xii+371. (Wiley: New York and Toronto; Israel Program for Scientific Translations: Jerusalem and London, 1973.) n.p.

RADIOECOLOGY began during the 1920s with studies of the biological effects of ionising radiation on living organisms in regions with high concentrations of natural radionuclides. By the 1950s it had become clear, at least to the Soviet Union, that the wider environmental effects of increasing radiation levels (especially from atmospheric nuclear testing) were so poorly understood that a vastly enhanced research effort was required. This book, written because the "work done by Soviet scientists has been ignored in published material outside the USSR", reveals just how seriously the Soviet Union takes the problem and how extensive their work

The two fundamental problems in radioecology are to determine how radionuclides migrate within biogeological systems and how ionising radiations affect microorganisms, plants and animals. The \*17 chapters describe Soviet researches into the ways that radionuclides (natural and artificial) and radiation behave in soils, forest communities, crops, food chains, natural pastures, wild and farm animals, the far north, water, fish, aquatic plants and man. There is also

a short discussion about the practical problems associated with the measurement of radioactivity in complex natural environments.

Many of these studies have evidently been undertaken with an eye to the consequences of exploiting nuclear energy for peaceful purposes. The editors see nuclear power taking a "prominent place" in the Soviet Union in the near future and envisage the extensive use of nuclear explosions in mining and construction. This being the case, they argue that an understanding of the ecological effects of radioactive pollution must "play an important role in the drafting of suitable restrictions".

Peter J. Smith

# Renewed hope for developmental biology

Experimental Studies of Amphibian Development. By E. Hadorn. Pp. vii + 138. (Springer-Verlag: Berlin, Heidelberg, New York, 1974.) \$8.20.

This short and excellent book is a translation from the German, designed "to introduce the reader to experimental research on development".

Developmental biology is experiencing what Professor Hadorn archly describes as a "Period of Renewed Hope" but many would say that it still remains in a delicate condition. One problem is a growing mass of experimental data that is too flexible and provides unconvincing support for too many theories. Another is that we do not know which organisms to concentrate on. The traditional choice has been the Amphibia, which Hadorn makes the subject of his book. Yet his presentation is far from traditional; his method is to avoid the litigious citation of references and to concentrate on describing a series of clean experiments while omitting the messy

Professor Hadorn guides us through the growth, of an individual with experimental analysis as we go along. He mixes deep descriptions of such knotty problems as gastrulation and induction with the light relief of metamorphosis and the mating habits of newts. The book describes many classical experiments and also includes recent discoveries; for instance, we are told that Millipore filters, long used by deluded embryologists as supposed barriers to cell contact, do not act as barriers at all.

The description and diagrams are clear and the subject matter well chosen. In the past, developmental biology has suffered from heavy presentation, but this book offers a delightful contrast.

Peter Lawrence

## Broad visual scope

The Vertebrate Retina: Principles of Structure and Function. (A Series of Books in Biology.) By R. W. Rodieck. Pp. x+1044. (W. H. Freeman: San Francisco, 1973.) \$39.50.

According to the author this book is an attempt to explain in a simple way, what is known about the organisation and function of the vertebrate retina. That is a formidable task, to which the author devotes over 900 concisely written pages. The coverage is comprehensive, ranging from basic concepts in light and photochemistry, through visual pigments, anatomy and ultrastructure, development, electro-physiology, and behaviour. The result is a real compendium; information and an entry into the literature can be found for topics as diverse as the retinal structure of deep-sea fishes and the characteristics of human colour vision.

It is very unusual to find a book with this breath of cover written by a single individual. The advantages: of having only one author are displayed clearly: the plan is coherent, the style of writing is uniform, and repetitions are avoided. There are, of course, also disadvantages. In particular, the coverage is necessarily uneven since it is difficult or impossible for any one individual to be expert in all the fields that are dealt with. In general, I found the coverage of those topics I know little about impressive and very interesting, whereas in those topics with which I am more familiar the treatment seemed rather oversimplified. The treatment of behavioural work with infraprimates seems particularly inadequate. Colour vision in fishes, for example, is dealt with in six lines, including an endorsement of Walls' statement that the best that can be said is that no fish is known not to have colour vision. In fact, there is a great deal of data on that topic, including determinations of wavelength discrimination and spectral saturation functions, and demonstrations of trichromacy, colour mixture, colour contrast, and constancy. Such data are clearly important in view of the great amount of electrophysiological work in that field. It is possible to single out other topics which receive similarly incomplete treatment, but that would be invidious since the general impression is not of the gaps, but of the striking completeness of the description the book gives of vision at the retinal level.

The book is written in a conservative style, presenting a balanced view of the topics and problems raised. Such speculation as occurs is restrained, and is closely attached to experimental data. The book is therefore probably more suited to readers who already have a

reasonable knowledge of vision than it is to, for example, beginning students. The book is without doubt a valuable addition to the literature, and probably represents the most comprehensive review of the whole field that is available at present. References are included up until 1972, so that some of the material is a little out of date, but that is inevitable in a book devoted to a rapidly developing field.

One unusual feature is the complete translation of Ramon y Cajal's monograph on the retina, originally published in 1893, which is included as an appendix. This is, in fact, the second English translation of this work to appear recently, and we should be grateful that after all these years this fundamental study is becoming readily available to English-speaking readers.

W. R. A. Muntz

#### Cold avian studies

Bird Migrations: Ecological and Physiological Factors. Edited by B. E. Bykhovskii. Pp. v+298. (Halsted, a division of Wiley: New York and Chichester. Israel Program for Scientific Translations: Jerusalem, April 1974.) £12.00.

This book is not, as may be expected, a general textbook, but rather a collection of five papers linked together because the work on which they were based was carried out at Rybachi (formerly Rossitten) in the south-eastern Baltic. Paevskii presents detailed lists of ringing recoveries and species maps, which take up two fifths of the book.

Blyumental considers the development of the autumn migratory state based on physiological examinations of 80,000 birds of 15 species. Lyuleeva discusses the energy requirements of swallows in flight during migration. Two short papers by Dol'nik and Gavrilov are on the calorific equivalent of body weight variations in chaffinches and on energy metabolism during flight in some passerines.

It is certainly very useful for those lacking access to the Soviet literature to have these translations. The only pity is that they have to be so expensive. The hard-back format seems to be an unnecessary luxury.

Many western researchers are unaware of the mass of work on bird migration work that has been going on in the Soviet Union. This collection of papers will open their eyes. An even wider deployment of Soviet workers and funds in this general field is at present under way.

One cannot but have reservations about the methods of Lyuleeva. Apart from allowing birds to starve and die in refrigerators, she devised an experiment of profound nastiness. In order to estimate the amount of energy expended in flight, she caught 30 swallows on their nests, weighed them and released them up to 70 km away. To prevent them taking sustenance on the return journey she sewed their beaks shut. She recaptured and reweighed only 17. Any scientist with a spark of decency will be revolted by such unthinking, useless brutality.

G. V. T. Matthews

Chinese bronze sculpture from the middle Chou period (circa 900-600 BC). The patterns represent hair whorls. From The Husbandry and Health of the Domestic Buffalo. Edited by W. Ross Cockrill. Pp. xiv+993. (Her Majesty's Stationery Office: London, 1974.) £8.00; £20.00.

### Time for plates of turtle

Sea Turtles and the Turtle Industry of the West Indies, Florida and the Gulf of Mexico. Revised edition by Thomas P. Rebel. Pp. 250. (University of Miami: Coral Gables, Florida, March 1974.) \$10.00.

It has often been pointed out that our exploitation of the food resources of the sea remains very largely at the hunting and gathering level. We consume not merely very little of the primary plant production of the sea but very little of the herbivore life too. Mostly, we consume predators further up—sometimes much further up—the food chains, with heavy losses of energy on the way. A book which discusses a, tensively annotated. group that includes important herbivores is, therefore, welcome.

The aim of this book is practical the assemblage of the available information necessary "to the proper development and control of our turtle resources". Dr Rebel starts with the description, identification and distribution of marine turtles, which is accompanied by good figures. Then he reviews what is known of the life history of the six species of turtles found in the western Atlantic and adjacent

#### Television:

With a programme entitled "The greatest advance since the wheel" Horizon (BBC2, November 25, 9.25 p.m.) hit top form yet again. The great advance referred to is superconductivity, which, we were told, is now at the same stage of development as was aviation just before Lindbergh's epic flight. If some similar breakthrough could be achieved with a dramatic development involving superconductivity, then industry would have to recognise the enormous potential offered by developments in the laboratory over the past few years.

Having hit the viewer with this dramatic theme, the programme settled down in slightly more sober vein, and care was taken not to overdramatise achievements already made, nor to underestimate the difficulty of getting industry to provide funds to develop the full potential of superconductivity. As one researcher put it, "you can never convince economists that innovation is worthwhile unless there's a war or crisis". But this innovation does • meed scarcely any power to run, just a seem genuinely worthwhile, though I doubt that it can achieve success in all the diverse areas covered in the programme.

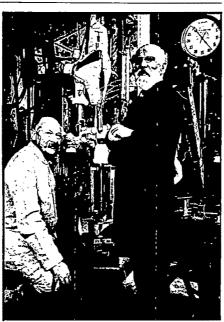

Superconducting magnets are, of course, already in use in powerful accelerators and fusion research experiments. Their advantages are that they

seas; these are all the marine turtles known in the world save a seventh species in Australasian waters. This part of the book contains many scattered pieces of information with gaps in between; separate observations have been recorded in disparate fashions. For none of the species of turtle do we have a complete life history, even in outline, but that is no fault of the author's-it reflects the dearth of sustained and methodical observation.

Turtle fishing and the commercial uses of turtles are reviewed and the author describes the progress which has been made in the cultivation of turtles and makes an assessment of the future prospects. A valuable final feature of the book is a bibliography of nearly a hundred pages covering academic as well as practical matters, which is ex-

Considering the greed with which turtles have been consumed at all stages of their lives with never a thought for the morrow it is astonishing that there is yet time to conserve and exploit them sensibly. Dr Rebel's book gives us reason to believe that turtle populations can be rebuilt and managed, to give a sustainable yield of animal protein and by-products. Let us hope that Dr Rebel will have the reward of seeing this begin to happen in his lifetime.

Garth Underwood

J. D. van der Waals (right) and H. Kamerlingh Ounes-pioneers in the field of superconductivity

few kilowatts to keep the helium in the liquid state, and they don't heat up. We were shown prospects of two really big developments: d.c. motors and a.c. generators.

The former is still looked on with suspicion by industry, but seems to have been clasped to the bosom of the

Royal Navy, which is always interested in the prospect of more power from a motor which weighs less. This conjures up some bizarre visions—"it's no use. Sir, we've been hit in the liquid helium bath"- but no doubt such equipment would be no more vulnerable than the complex electronic computers which are already on many modern ships.

As for generating a.c. power with the aid of superconducting coils, industry, it seems, just doesn't want to know. Power generated in experimental setups is tiny by industrial standards: 1 MW, a fraction of 1% of the output of the standard generators used in power stations. The description of research in this area left me slightly puzzled. It seems that the development is so difficult because the superconducting permanent magnet must be made to rotate (cooling helium and all) inside the generator coils. Why, I wonder, do the experimenters not leave the magnet fixed and rotate the coils around it? There is probably a simple explanation, but the point should have been made clear.

There was also a slight puzzle in the otherwise straightforward explanation of superconductivity. According to Bardeen, Cooper and Schrieffer it seems that electrons travel in pairs through a superconductor, and that this prevents them being scattered by impurities in the metal. Perhaps that is what the mathematics tells us, but the physical description and animation offered by Horizon was too simplistic and perhaps too naive. Someone could have been on hand to offer more elucidation.

The programme ended as it began, with some more flamboyant stuff, this time about superconducting coils used in magnetic levitation trains. But hard core industrialists would probably have been more intrigued by two more straightforward uses of the new wonder, mentioned earlier in the programme. The powerful magnetic fields produced with the aid of superconductivity can be used to separate weakly magnetic ores from rock which would not otherwise be economically workable; and in a similar way suspended colloidal iron oxide can be removed from water, taking with it just about any impurities which may be present. That offers a better way to treat sewage, to scrub the dirty waters of polluted rivers clean, and so on. And there is no pie in the sky about these straightforward applications of superconductivity.

Perhaps not quite "the greatest advance since the wheel"-it would. incidently, be interesting to ask a few people what their candidate for this title would be-but good televised science. And that's something to be grateful for. John Gribbin

# obituary

#### Sir Eric Rideal

SIR ERIC RIDEAL, MBE, FRS, the distinguished physical chemist, died on September 25, 1974. He was 84.

From Trinity Hall, Cambridge, Rideal went to Bonn and obtained his PhD there in 1913. After service in the Munitions Inventions Service, he returned to Cambridge in 1920 as Humphrey Owen Jones Lecturer in Physical Chemistry and ten years later became the first Professor of Colloidal Physics. In 1946 he left to be Director of the Davy-Faraday Research Institute and Fullerian Professor at the Royal Institution. He was appointed to the chair of physical chemistry at King's College, London, in 1950. He retired from this post in 1955 and was elected a Fellow in 1963. After his retirement he continued working at Imperial College, London.

#### H. A. Ferreira

HERCULANO DE AMORIM FERREIRA, the Portuguese climatologist, died on May 18, 1974. He was 78.

Ferreira became a professor at the Faculty of Sciences, Lisbon University in 1930 and taught there until 1965. From 1928 to 1937 he also taught at the Portuguese Military Academy and between 1933 and 1934 was visiting professor at Imperial College, London. He was the director of the Geophysical Institute Infante D. Luis in Lisbon from 1937 to 1964. In 1943 he was charged with the reorganisation of the National Meterological Service, which

he directed until 1965. He was an Under Secretary of State for Education from 1944 to 1946.

#### J. Chamberlain

JOHN CHAMBERLAIN died on October 11, 1974. He was 37.

He took his doctorate from Imperial College, London in 1962 and was appointed that year to the National Physical Laboratory. There, for the rest of his career, he worked on submillimetre wave Fourier Transform spectrometry and refractometry. He made important theoretical and practical contributions to precise measurements and was an authority on the high frequency dielectric properties of materials, including solids, liquids, gases and plasmas.

# **Announcements**

#### **Appointments**

Bernard Isaacs has been appointed to the Hayward Chair of Geriatric Medicine at the University of Birmingham.

H. A. Lee has been appointed to the chair of metabolic medicine at the University of Southampton.

George Edward Mawer has been appointed to the chair of clinical pharmacology at the University of Manchester.

I. C. Whitfield has been appointed to the personal chair of neurocommunications at the University of Birmingham.

#### Awards

Julian G. Edwards has been awarded the 1974 Achievement Award of The Worshipful Company of Scientific Instrument Makers for his development of a Pulsed Energy Laser Moni-

Maurice Ewing has been awarded posthumously the Penrose Medal of The Geological Society of America.

Alfred Edward Ringwood has been awarded the Arthur L. Day Medal of The Geological Society of America.

The Chemical Society is offering an additional award in 1974 which has been sponsored by the British Oxygen Company Limited. The award will be made to the author of the best original paper or papers issued in the past five years (since January 1, 1970) covering the chemistry and/or usage of oxygen. This award is available to men and women of British Nationality, including Commonwealth Citizens or those normally domiciled in the British Isles, and is not limited to Fellows of the Chemical Society.

Nominations and/or applications should be sent to Dr John F. Gibson, The Chemical Society, Burlington House, London W1V 0BN not later than January 31, 1975 and the relevant paper(s) must accompany any such nomination/application.

#### Miscellaneous

The Hollandsche Maatschappij der Wetenschappen (Dutch Society of Sciences) has the intention of publish. ing the correspondence of Professor H. A. Lorentz (1853-1928), who was Secretary to the Society during the last eight years of his life.

The editing committee would therefore greatly appreciate receiving any information from persons and institutions having in their possession or under

their custody letters written by Professor Lorentz, and to receive copies of these letters with the permission for their publication.

Please address all correspondence to: Hollandsche Maatschappij der Wetenschappen (Lorentz Committee), Spaarne 17, Haarlem, The Netherlands.

# **Arctic and Alpine Environments**

Edited by JACK D. IVES and ROGER G. BARRY An entirely new approach to

the study of arctic and alpine areas, systematically covering their climatic, hydrological and glaciological features, their flora and fauna, paleoecology, geomorphic and soil processes, archaeology, man's physiological adjustment to extreme environments, and his recent impact on them. The book is profusely illustrated with 226 line drawings and 49 black and white plates and will undoubtedly become the definitive work on the subject.

These specially designed Binders make attractive space-saving files for your Nature. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of Nature. Two volumes of Nature can be preserved in a single binder, (three binders will hold the six volumes published annually) and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains.

These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

# Essays in Biochemistry Volume 10 edited by P. N. Campbell and F. Dickens

November 1974, xii+156 pp., £2.60/\$7.00.

0.12.158110.1

Contents

Setsuro Ebashi: Regulatory mechanism of muscle contraction with special reference to the Ca-troponintropomysin system.

David J. Manners: The structure and metabolism of starch.

David Givol: Affinity labelling and topology of the antibody combining site.

P. N. Magee: Activation and inactivation of chemical carcinogens and mutagens in the mammal.

Author index. Subject index. Cumulative listing (vols. 1-10).

## The Interpretation of Multiple Observations

F. H. C. Marriott

November 1974, x+118 pp., £3.50/\$9.00.

0.12,473450.2

There are two main stages at which mistakes occur in the numerical analysis of multivariate datain the choice of a particular method of analysis, and in the interpretation of the results thereby gained. The book provides a critical examination of the most important available numerical methods, gained. The book provides a critical examination of the most important available numerical methods, relating them to the types of data for which they are suitable, explaining the questions they are trying to answer and the assumptions they involve. In discussing the classical techniques of discriminant analysis, factor analysis, principal components and canonical analysis, and more recent developments in the fields of cluster analysis and scaling methods, stress is laid on the practical aspects of the examined methods, while mathematics is kept to a minimum. This work will be of great value to all scientists needing to analyse multivariate data, including biologists, geologists, soil scientists, psychologists and biomathematicians.

The Analysis of Organic Materials An International Series of Monographs

## Chemical Analysis of Organic Compounds Volumes 2 and 3

T. R. Crompton

Volume 2

November 1974, x+164 pp., £5.00/\$13.25.

0.12.197302.6

Volume 3

November 1974, x+212 pp., £6.50/\$17.25.

0.12.197303.4

Here are the second and third volumes in this critical review of the organometallic compounds of all the elements, compounds which are attracting increasing interest all over the world. In these reference volumes the author takes account of the international literature on the subject up to the end of 1972. These volumes cover elements from Group 4A and Group 4B: Volume 2 includes a major chapter on silicon and a minor chapter on titanium, zirconium and hafnium, while Volume 3 deals with germanium, tin and lead. Each chapter provides a complete review of all aspects of the organocompound in question, together with critical comments on the relative importance, merits and demerits of the methods of analysis applicable.

## The Physical Chemistry of Dye Adsorption

I. D. Rattee and M. M. Breuer

November 1974, xiv+324 pp., £8.60/\$22.25.

0.12.582550.1

Here is an up-to-date work which brings together important information on experimental data produced by current research and relates it to general scientific knowledge regarding surface phenomena. Thus it is able to present a more unified approach to the dye adsorption process than have previous books on the subject, at the same time defining more clearly the role played by research in relation to technological demands. This leads to a treatment which is much more informative to the research chemist and enables the main investigation groups in general science, medical and dye/textile polymer research, to be considered together. This volume should appeal to a wide audience—including students and researchers in cosmetic, colour, textile and polymer chemistry, surface and colloid chemistry, histology, food science, medicine and ecology and in many other areas concerned with interfacial phenomena.

## Advances in Parasitology Volume 12

Organized and edited by Ben Dawes

November 1974 xii+432 pp., £10.50/\$27.75

#### APPOINTMENTS VACANT

#### THE DEPARTMENT OF PSYCHOLOGY PRINCETON UNIVERSITY

PRINCETON UNIVERSITY
anticipates several openings for the 1975–76
academic year. One is at the Full Professor level
in social psychology, where we seek an addition
to our ongoing programme in social psychology.
The other(s) at the Assistant Professor level are in
general experimental psychology, with concentration
in animal behaviour, developmental and comparative psychology, or personality research. These
latter anticipated openings are not rigidly tied to
any specific area of expertise. Sheer excellence in
research and teaching will override area-of-interest
considerations.

Nominations and applications should be sent to
the Chairman, Department of Psychology, Green
Hall, Princeton University, Princeton, New Jersey
08540. We are an equal opportunity employer with
a vigorous affirmative action programme. (2022)

#### PAHLAVI UNIVERSITY DEPARTMENT OF BIOLOGY SHURAZ, IRAN

Applications are invited at the assistant/associate professor's level for the following positions on two year renewable contracts with an annual salary range equivalent to U.S. \$12,000 to U.S. \$16,000; depending on qualifications and teaching experience.

Please send written applications, curriculum vitae and confidential recommendations from three referees to the Department of Biology, Pahlavi University, Shiraz, Iran.

Applications are invited for the following fields:

1. Bacterial/Viral genetics

2. Developmental genetics

3. Cell organelle physiology

4. Plant Biochemistry

5. Animal physiology: osmoregulation

6. Ornithology

7. Insect physiology

8. Plant growth regulators

9. Invertebrate zoology/protozoology

10. Terrestrial animal ecology/plant ecology

11. Ichthyology

12. Reproductive physiology

13. Vertebrate neurophysiology

14. Mycology

(2100)

(2100)

.. (2106)

#### DALHOUSIE UNIVERSITY

Department of Pharmacology

Department of Pharmacology

Applications are invited for a POSTDOCTORAL FELLOWSHIP in one of the following fields: (i) Cardiovascular Pharmacology, (ii) Toxicology of Environmental Pollutants, (iii) Transport of neurotransmitters and electrolytes into presynaptic nerve terminals, (iv) Autonomic Pharmacology and Electrophysiology of Smooth Muscle.

Applicants should not be more than 35 years of age, and should hold a Ph.D. degree with specialisation in one of the above mentioned areas from a recognised university. Initially this fellowship is granted for one year only, the annual stipend being \$9,100 (presently under revision) and subject to income tax. Travel grants may be provided to the fellow and spouse, if married.

Applications must be received no later than January 30, 1975, togther with a list of publications, curriculum vitae and at least two letters of recommendation to be sent directly from persons well acquainted with the applicant's personal and academic record to: Dr J. G. Aldous, Chairman, Department of Pharmacology, Sir Charles Tupper Medical Building Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7.

(2106)

# CSIRO **AUSTRALIA**

## DIVISION OF MATHEMATICS AND STATISTICS

#### CANBERRA A.C.T.

## RESEARCH SCIENTISTS (3 POSITIONS)

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

GENERAL: The Organization's Division of Mathematics and Statistics has over 100 staff members, two thirds of whom are professional scientists located at various regional centres throughout Australia.

The interests of the Chief of the Division, Dr. J. Gani, include applied probability, population processes and epidemic models. The Canberra group currently includes 7 research scientists and is led by Dr. C. C. Heyde, whose main interest is stochastic processes (particularly limit theory). Areas of interest of the other scientists are applied multivariate methods, experimental design, fluid mechanics (including biological aspects), Markov chain modellings, data analysis and genetic—environment inter-action.

Excellent computer facilities are available; the group uses the Cyber 76 installation of the Organization's Division of Computing Research, and also has its own PDP 11/10.

The group works in close collaboration with the Departments of Statistics and Applied Mathematics at the Australian National University, with which joint seminars are currently organized.

DUTIES: To carry out divisional and personal research projects, both theoretical and applied. To act as consultants in planning the research and applying mathematics and statistics to the scientific projects of other CSIRO Divisions.

QUALIFICATIONS: A Ph.D. degree or its equivalent; demonstrable research ability with experience in relevant fields of application. While the appointees' interests may lie in any area of probability, statistics or applied mathematics, some preference will be given to applicants whose fields are allied to those of the existing research group.

**SALARY:** Appointments will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A10,778 to \$A16,187 p.a.

**TENURE:** Either a three-year fixed term or an indefinite appointment may be negotiated. Indefinite appointment carries Australian Government Superannuation benefits subject to normal conditions.

INTERVIEWS: Dr. Gani will be visiting the United Kingdom between 23rd December, 1974, and 1st January, 1975, and North America between 1st January, and 7th January, 1975.

Those interested in discussing the appointment with him should contact either the Chief Scientific Liaison Officer, Australian Scientific Liaison Office, 64 Kingsway, London, WC2B 6BD or the Counsellor (Scientific) Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington D.C. 20036 U.S.A., in ample time to enable suitable arrangements to be made.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 442/10 should reach:—

The Personel Officer, Australian Scientific Liaison Office, 64-78 Kingsway, LONDON, WC2B 6BD

by the 20th December, 1974.

Applications in U.S.A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C. 20036, U.S.A.

(2196)

#### GENEVA RESEARCH CENTRE

seeks

for the GROUP OF BIOCHEMISTRY AND BIOPHYSICS a BIOLOGICAL SCIENTIST, probably a BIOCHEMIST or IMMUNOLOGIST, with an interest in experimental carcinogenesis and tumour immunology.

The candidate chosen will be expected to develop new areas of research and to assume responsibility for the continuation of certain activities.

Preference will be given to persons holding a Ph.D. or medical degree with postdoctoral experience but others interested with strong research background are invited to apply:

and

## for the DEPARTMENT OF APPLIED CHEMISTRY AND PROCESS ENGINEERING

a PHYSICAL CHEMIST, with preferably, but not necessarily, a few years' experience of research in industry.

Candidates should have a high level of scientific ability, and should be specialised in the following fields:

- gas-solid interactions
- characterisation of porous or particulate matter
- reaction kinetics
- heterogeneous combustion phenomena

Experience in the natural and synthetic polymer field would also be an advantage.

The position proposed involves working in a research team whose task is the development of new products and processes, with the help of a wide range of modern experimental techniques.

Please address full particulars, with curriculum vitae, photograph and salary requirement to the Personnel Manager, Battelle, 7 route de Drize, CH-1227 Carouge-Geneva, Switzerland. (2219)

# THROMBOSIS RESEARCH

Inveresk Research International is currently seeking an experimental scientist to join a team working on comparative aspects of thrombus induction in animals. Candidates should preferably have obtained their doctorate in pharmacology, physiology or a related discipline, but experienced honours graduates will also be considered. Experience in micromanipulation is desirable, as is the ability to develop new experimental techniques.

I.R.I. is a modern, expanding contract research organisation, offering good working conditions and fringe benefits. The salary for this post will be in the range £2,350 to £3,400.

Please write for an application form, quoting reference 0441, to Miss J. M. Dunbar, Inveresk Research International, Inveresk Gate, Musselburgh EH21 7UB, Midlothian. (2191)

# FIELD STUDIES COUNCIL TUTOR

in Biology at SLAPTON LEY FIELD CENTRE, near Dartmouth. Single, good degree, emphasis on freshwater and/or marine ecology. Educational qualifications desirable. Research opportunities with the Slapton Research Unit. Salary £1,200 by 75 to £1,350 plus free board and lodging. Appointment early 1975. Closing date for applications December 31, 1974. Further details and application forms from The Director, Field Studies Council, Preston Montford, Montford Bridge, Shrewsbury SY4 1HW.

#### TUTOR

in Biology at DALE FORT FIELD CENTRE, Haverfordwest. Single, good degree, emphasis on marine ecology, botanical interest an asset. Educational qualifications desirable. Research opportunities, Salary £1,200 by 75 to £1,350 plus free board and lodging. Appointment early 1975. Closing date for applications December 31, 1974. Further details and application forms from The Director, Field Studies Council, Preston Montford, Montford Bridge, Shrewsbury SY4 1HW. (2177)

## CITY & EAST LONDON AREA HEALTH AUTHORITY (T)

DEPT. OF MEDICAL MICROBIOLOGY, ST. BARTHOLOMEW'S HOSPITAL

Technician or research assistant required on a project to evaluate physico-chemical methods of bacteriological diagnosis. The post would be suitable for a person with either technical or university training. Some microbiological knowledge is essential and an interest in machines and automation an advantage. Position available for one calendar year at present.

Salary (according to experience) up to £2,238 p.a. plus London Weighting and "Threshold".

Applications stating age, qualifications and experience to Personnel Office, St. Bartholomew's Hospital, London, E.C.1, quoting ref. R/3998/N. Closing date: December 23, 1974. (2175)

## UNÍVERSITY OF BRISTOL DEPARTMENT OF ZOOLOGY

#### POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from cell biologists and/or developmental biologists for the post of Post-Doctoral Research Assistant to collaborate in an M.R.C. supported project on the effects of carcinogens on lung tissues. Applicants should have research experience in cultivation of tissues in vitro, in electron microscopy, and in autoradiography; experience in the field of carcinogenesis would be an advantage.

The appointment is available now for a period of up to 3 years at an initial salary of up to £2,247 per annum plus Threshold supplements.

Applications with details of qualifications and experience and the names of two referees should be made to Dr. J. W. Dodsor, Department of Zoology, University of Bristol, Woodland Road, Bristol BS8 1UG. (2172)

# THE UNIVERSITY OF ADELAIDE WAITE AGRICULTURAL RESEARCH INSTITUTE

Applications are invited for two RESEARCH positions in the Department of Plant Physiology:

(1) To work on Regulation of the Accumulation of Starch in Cereal Endosperm, involving methods of enzyme assay and/or identification and measurement of metabolic intermediates. (2) To work on the Regulation of Sterol and Gibberellin Biosynthesis by 'Plant Growth Retardants, involving methods of extraction, identification and bioassay of isoprenoid compounds. An applicant should have a higher degree or an Honours degree in Biochemistry or Plant Physiology, and preferably have had some research experience.

The appointments are for one year in the first

nave nau some research experience.

The appointments are for one year in the first instance, Initial salary will be in one of the following scales, depending on qualifications and experience: Professional Assistant \$A6,060 to 535 (2) to 7,130; Professional Officer Grade I \$A7,664 to 534 (1) to 535 (2) to 9,268. General conditions of appointment may be obtained from the Registrar.

APPLICATIONS, giving details of academic record and experience, and marital status, together with names and addresses of two referees, should reach the Registrar of the University, G.P.O. Box 498, Adelaide, South Australia 5001, not later than December 31, 1974. (2182)

# SCIENTISTS AND TECHNOLOGISTS

# GET TO THE HEART OF NUCLEAR POWER

British Nuclear Fuels Limited is one of the world's leading suppliers of nuclear fuel cycle services and is expanding its activities to meet the national and international growth of nuclear power.

BNFL is therefore in a position to offer careers of outstanding professional interest and potential to GRADUATE SCIENTISTS AND TECHNOLOGISTS.

We are looking for physicists, chemists, metallurgists and engineers with (or likely to obtain) PhD, MSc or good honours BSc for a wide variety of work in:-

#### **PLANT OPERATIONS**

BNFL operates chemical and engineering plants which are among the most sophisticated and advanced in the world. Vacancies exist which offer valuable technical and managerial experience in plant operation.

#### **ANALYTICAL SERVICES**

The nuclear industry calls for the highest standards of quality, and BNFL's production facilities have the support of analytical service departments, which use many of the most modern techniques of analysis, requiring all the skills and resources of the graduate.

#### **HEALTH PHYSICS**

BNFL's Health and Safety Departments at BNFL's establishments are responsible for advising management on the application of international and national regulations and codes of practice for the safe handling of nuclear materials. There are vacancies in these departments for graduates from many disciplines.

#### TECHNICAL DEVELOPMENT

Supporting the production teams are the staffs of technical departments comprising people from many branches of science and technology. Their work includes evaluating plant performance and carrying out development projects to improve processes and techniques. And there are posts in these departments which need to be filled.

These posts offer challenging and responsible work in a stimulating environment. BNFL's policy is to supplement this experience with training and career development programmes which fit staff for higher managerial posts.

#### The BNFL locations are:-

#### WINDSCALE, Cumbria

A major world centre for the reprocessing of nuclear fuels. Windscale is on the Cumbrian coast within easy reach of the Lakeland countryside.

#### SPRINGFIELDS, near Preston

Suppliers of fuel to Nuclear Power Stations in the UK and overseas. Near to the residential and leisure amenities of the Fylde countryside and Lancashire coast.

#### **CAPENHURST**, near Chester

The BNFL uranium enrichment complex – one of the locations for the exciting centrifuge project – in pleasant rural surroundings near to attractive residential and leisure areas.

#### **HEAD OFFICE - RISLEY, near Warrington**

A major centre of modern technology, sited near the intersection of the M6 and M62 motorways and thus within easy commuting distance of the whole North West.

#### **PAY AND CONDITIONS**

Salaries are on a scale £2,800 – £3,800 plus threshold payments and there are excellent prospects of promotion to the next grade, currently paying up to £4,900. With 22 working days holiday, and an attractive contributory superannuation scheme, the general service conditions are those expected of an organisation with a major role in one of the world's most exciting and expanding technologies.

# SEND COUPON NOW FOR APPLICATION FORM (FREEPOST — NO STAMP REQUIRED) OR PHONE WARRINGTON 35953 Ext. 2608 or 2612

TO: Company Staff Manager, British Nuclear Fuels Limited, FREEPOST, Risley, Warrington WA3 1BR
Please send me application form for vacancies for Scientists and Technologists.

## Belize

#### Forestry Inventory Officer

To be responsible for the running of a Forestry Division. Duties cover the entire spectrum of general forestry practices. Applicants should have B.Sc. (Forestry) and some experience in the duties of the post. Experience in tropical forestry an advantage. Appointment for 2 or 3 years.

Salary in range £2,700 to £4,686 p.a. which includes a supplement in range £1,260 to £2,640 p.a., Terminal gratuity  $20^{\circ}_{\circ}$  of basic salary. Other benefits include free family passages, paid leave, childrens education allowances, and subsidised accommodation. An appointment grant of up to £200 and an interest free car purchase loan of up to £600 may be payable in certain circumstances. Applicants should normally be citizens of, and permanently resident in, the United Kingdom.

For full details and an application form please apply giving age and brief details of qualifications and experience to:-

Appointments Officer

#### Ministry of Overseas Development

Room 301 Eland House Stag Place London SWIE 5DH

(2210)

### **GOVERNMENT OF FIJI** HYDROLOGIST

Required to control the hydrological organisation of the Public Works Department.

Salary in the range £2,600 to £3,740 a year which includes an allowance, normally tax free of £696 to £996 a year. Generous

Appointment will be on agreement for 30/36 months initially. Candidates must have a wide experience ranging over 10 years in general hydrological works, with particular emphasis on the collection, collation, and evaluation of rainfall and run-off data, and the

location and establishment of hydrological stations. Other benefits include free family passages, education allowances, Government quarters at moderate rental and generous paid leave. An appointment grant £300 and car advance £600 may be payable.

The post described is partly financed by Britain's programme of aid to the developing countries administered by the Ministry of Overseas Development.

For further particulars you should apply, giving brief details of experience to:

# crown agents

M Division, 4 Millbank, London SW1P 3JD, quoting reference number M3D/730217/NF. (2185)

#### "METALS ABSTRACTS"

The international abstracting service for metallurgy offers permanent positions as SENIOR EDITORIAL ASSISTANTS. The work consists of editing and checking abstracts for publication. A science degree, preferably in metallurgy, physics, or chemistry, is necessary and a working knowledge of a foreign language would be an advantage.

Applications, stating age, education, qualifications, and experience, to Dr T. Graff, Metals Abstracts, The Metals Society, 1 Carlton House Terrace, London SWIY 5DB.

#### **GREATER GLASGOW** HEALTH BOARD

Applications are invited for a TOP GRADE VIROLOGIST to develop the Viral Hepatitis Reference Laboratory of the Regional Virus Laboratory at Ruchill Hospital, Glasgow. The work is associated with the University Department of Infectious Diseases, the Communicable Diseases (Scotland) Unit, and the Blood Transfusion Service. It involves continuing routine service and surveillance as well as research and technical development. Applicants should have experience of human and animal virology. Salary and conditions in accordance with Whitley Council scale for Top Grade Scientists.

Further details can be had from the Secretary,

Further details can be had from the Secretary, Greater Glasgow Health Board, Room 117, 351 Sauchiehall Street, Glasgow, G2 3HT, to whom applications (I copy) should be sent with details of age, qualifications, experience, present appointment, and the names of two referees, not later than December 21, 1974. (2211)

#### UNIVERSITY COLLEGE DUBLIN DEPARTMENT OF BOTANY

Applications are invited for a post on the Academic Staff in the Department of Botany. Preference will be given to a candidate with experience in whole plant physiology.

The current salary scales are in the range:
College Lecturer
Assistant Lecturer
£3,737 to £4,927
£2,590 to £3,535

Entry point on the relevant scale will be in accordance with qualifications and experience.

A non-contributory pension scheme and family allowances are additional to salary. An alternative contributory F.S.S.U. type pension scheme is also

Applications including the names of three referees should be sent to:—
Mr. J. P. MacHale,
Secretary and Bursar,
University College,
Belfield,
Dublin 4.

Latest date for receipt of applications extended to Monday, December 30, 1974. (2209)

### IMPERIAL COLLEGE WATER/POLLUTION **CHEMIST**

Research Assistant required to join multi-disciplinary research team to work on Geochemical aspects of Heavy Metal Pollution. Applicants should preferably have postgraduate or other experience of the chemistry of trace elements in waters and sediments. The appointment will be on the Lecturer scale within the salary range £2,331 to £3,144 including London allowance according to age and experience plus threshold payments. Applications to Professor J. Webb, Applied Geochemistry Research Group, Geology Department, Imperial College, London SW7 2BP.

#### UNIVERSITY OF EDINBURGH DEPARTMENT OF AGRICULTURE

#### LECTURER IN CROP PRODUCTION

Applications are invited for the post of Lecturer, who will be responsible to Professor R. C. F. Macer (Professor of Crop Production) for teaching in aspects of crop production in undergraduate and postgraduate courses, and for the initiation of a research programme in a selected area of crop production.

Applicants should have a degree in Agriculture or Agricultural Science, and postgraduate research experience would be an advantage.

Salary on scale £2,118 to £4,896 plus F.S.S.U.

Applications (giving the names of 2 referees) should be sent to Professor F. W. H. Elsley, The Edinburgh School of Agriculture, West Mains Road Edinburgh EH9 3JG, from whom further particulars may be obtained. The closing date is December 30, 1974. Please quote reference 1043.

Applications are invited for the post of Director at the Royal Society research station on Aldabra Island.

The person appointed will be responsible for the administration of the station and the direction of staff and will supervise a conservation programme concerned mainly with terrestrial but also marine ecology and assist visiting scientists and research students.

Applicants should be at least 25 years old, have a science degree or equivalent qualification, be medically fit and should preferably have expéri-ence of living in isolated conditions, particularly in the tropics.

Salary within the range £2,600 to £3,300 p.a., less a standard charge for subsistence and free transport to and from the atoll will be provided.

The appointment will be for one year in the first instance, with possible renewal for a further eight months. Two months' terminal leave on full salary is granted after one year's service and four months' leave after twenty. Applicants may be accompanied by wives but no children.

Applications with full details of career to date and names of two referees, should be sent to:

The Executive Secretary (L.U.M.), the Royal Society, 6 Carlton House Terrace, London, S.W.1, by January 10, 1975. (2205)

#### UNIVERSITY OF NEWCASTLE UPON TYNE

#### DEPARTMENT OF CHEMICAL ENGINEERING

Applications are invited from suitably qualified persons for appointment as SENIOR RESEARCH OFFICER until July 31, 1976. Candidates should have a good knowledge of the physics of diffusional processes and be interested in joining a team studying mass transfer phenomena in liquidiquid systems. The person appointed will also be expected to undertake limited teaching duties.

Salary will be in the range £2,580 to £4,896 according to age qualifications and experience, plus standard threshold payment of £229.68 p.a. Membership of a University superannuation scheme will be required.

Applications should reach Professor J. D. Thornton, Department of Chemical Engineering, University of Newcastle upon Tyne, not later than January 4, 1975. (2206)

#### TRENT POLYTECHNIC NOTTINGHAM

#### RESEARCH ASSISTANT/ **DEMONSTRATORS**

DEPARTMENT OF PHYSICAL SCIENCES Good honours graduates desirous of working for a higher degree are invited to apply for posts relating to the following projects:-

- (a) Synthesis of pharmacology active hetero-cyclic compounds.

- (b) Synthesis and polymerization of novel monomers derived from monosaccharides.
   (c) Studies on reduced pyrazines.
   (d) Synthesis acid reactions of sulphur heterography.
- (e) Reduced porphyrins.
- Salary £1,250 to £1,350 to £1,450 per annum on a three year contract.

Application form and further details from The Chlef Administrative Officer, Trent Polytechnic, Burton Street, Nottingham, NGI 4BU. (2208)

Department of Health and Social Security British Pharmacopoeia Commission, London

# Chemists/Pharmacists

■ Secretarial and editorial work for British Pharmacopoeia Collection of data from technical journals, foreign pharmacopoeia for reports to committees Assist in work for European Pharmacopoeía.

☐ Degree or equivalent in Pharmacy ☐ Some relevant post-qualifying experience ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£3100 to over £4000) or Scientific Officer (over £2200 to £3300) according to age and experience \( \subseteq \text{Ref: SB/6/KD.} \)

☐ Application forms (for return by 10 January 1975), from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke 29222 ext. 500 (or, for 24 hour answering service, London 01-839 1992).

#### Department of the Environment Water Data Unit, Reading

# **Biologist**

■ Investigate relationship between river biota and degree of pollution in controlled waters Advise on biological aspects of the River Pollution Survey of England and Wales.

☐ 1st/2nd hons degree in biology ☐ 4 years' post-graduate experience in field of river biology ☐ Experience of surveying river biota and collecting such data in the field desirable ☐ Age under 32 ☐ Appointment as Senior Scientific Officer (£3350 to over £4650) ☐ Ref: SA/4/HJ.

☐ Application forms (for return by 13 January 1975), from Department of the Environment, Room 446, Lambeth Bridge House, Albert Embankment, London SE1, telephone 01-211 3325 or 7158.

**Procurement Executive, Ministry of Defence** Microbiological Research Establishment, Porton Down

# **Pathologist**

■ Study into pathogenesis, pathology and immunology of infectious diseases (mainly viral) Investigate nature, cause and characteriza-tion of diseases in experimental animals by various routes of administration Work has particular application to vaccine research.

[] Ist/2nd hons degree in medicine or veterinary science or equivalent [] At least 4 years' post-graduate experience in pathology  $\square$  Age under 32  $\square$  Appointment as Senior Scientific Officer (£3350 to over £4650)  $\square$  Ref: SA/5/FQ.

# Virologist

■ Work on safety procedures and practices involving bacteriology and virology Take and assay samples Clinical laboratory work including: serological procedures, identification of pathogens, and blood counting; freeze drying; safety aspects of air filtration, radiation hazards, disinfection and sterilisation Instruct junior staff on safety and hygiene.

☐ FIMLT or degree in relevant scientific subject ☐ Several years' experience in hospital or laboratory practice, and the handling of toxic materials  $\Box$  Age normally under 30  $\Box$  Appointment as Higher Scientific Officer (over £2650 to £3600)  $\Box$  Ref: SA/6/FQ.

 $\square$  Application forms (for return by 9 January 1975), from Microbiological Research Establishment, Porton, Salisbury, Wilts SP4 oJG.

# UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for (a) LECTURESHIP or (b) ASSISTANT LECTURESHIP IN THE DEPARTMENT OF CHEMISTRY. Applicants with interests in Physical Chemistry would be preferred. Salary scales: (a) 136,168 to J\$9,768 p.a. (b) J\$5,006 to J\$5,486 p.a. (£! sterling=J\$2.11). F.S.S.U. Study and Travel Grant. Unfurnished accommodation, for maximum of three years at rental of 10% of salary, thereafter 20% of salary payable in lieu of housing. Family passages. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Detailed particulars are available and should be obtained from the same source before an application is made. (2233)

#### CELL BIOLOGIST/BIOCHEMIST

A postdoctoral position is available to work on the mechanisms of connective tissue turnover. The candidate must have a sound background in cell biology/biochemistry but experience in connective tissue research is not essential. The starting salary is £2,412 per annum for someone who has recently completed a PhD training. The appointment is for one year initially, but may be renewed for up to three years, and carries F.S.S.U. benefits.

Please send curriculum vitae and names of two referees to Dr J. J. Reynolds, Tissue Physiology Department, Strangeways Research Laboratory, Worts Causeway, Cambridge, CB1 4RN. (2215)

## ZOOLOGICAL SOCIETY OF LONDON

#### RECORDER

for the **Zoological Record**, a bibliography of the world's zoological literature. Duties include scanning literature and indexing of relevant material.

Applicants should possess a degree in Zoology. Linguistic ability and previous experience in information work would be helpful but not essential. Posts based at units at the British Library Lending Division, Boston Spa and the British Museum (Natural History).

Salary on scale £1,722 to £2,418, plus £228 London Weighting if applicable, plus £229 threshold payment (Weighting under review).

Applications, with brief details, in writing to: Managing Recorder, Zoological Record, P.O. Box 9, Wetherby, Yorkshire, LS23 7EG by January 6, 1975.

(2192)

#### RESEARCH ASSISTANT

To participate in M.R.C. funded project on the role of the neutrophil in allergic glomerular injury. Work in purpose built research block will include human and animal material. Medically qualified person (M.R.C.P. essential) would train in active nephrology department. To start in early 1975. Salary appropriate to grade.

Apply to: Dr P. Naish, Department of Nephrology, North Staffordshire Royal Infirmary, Princes Road, Stoke-on-Trent. (2222)

#### UNIVERSITY OF EDINBURGH DEPARTMENT OF CLINICAL SURGERY RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to work on the effects of hormones on mammary tumour growth and steroid metabolism in the DMBA treated rat. Applicants should have an honours degree in Biochemistry or a related biological subject. The appointment is suitable for a candidate wishing to study for a higher degree.

Applications, with curriculum vitae and the names and addresses of two referees, should be sent to Professor A. P. M. Forrest, Department of Clinical Surgery, Royal Infirmary, Edinburgh EH3 9YW, from whom further information can be obtained. Please quote reference 5059. (2201)

#### AUSTRALIA

#### PUBLIC SERVICE OF VICTORIA

Ministry for Conservation Fisheries and Wildlife Division

# Senior Research Officer

(Two Positions)

Yearly Salary: \$Al0,505 min. \$Al2,211 max.

#### POSITION No. 1

Ref. No. (N/02)

#### Duties

To carry out field and laboratory studies in marine productivity and energetics in relation to water quality characteristics; other research duties as directed.

#### Qualifications

An approved degree in Science, or other approved equivalent qualifications; appropriate training and experience as related to marine productivity and energetics; experience in experimental studies on productivity an advantage.

#### POSITION No. 2

Ref. No. (N/05)

#### **Duties**:

To carry out investigations into the quantitative ecology of marine systems with a view to assessing the effects of industrial and domestic development of the area; other research duties as directed.

#### Qualifications:

An approved degree in Science, or other approved equivalent qualifications; appropriate training and experience in marine ecology with special emphasis on energetics and productivity; experience with meiofaunal ecology an advantage.

Applications quoting reference number (N/02), should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Tuesday, December 31, 1974, together with statements of experience and qualifications and date and place of birth. (2189)

#### LIVERPOOL SCHOOL OF TROPICAL MEDICINE DEPARTMENT OF TROPICAL MEDICINE **BIOLOGIST/PARASITOLOGIST**

Research Assistant required to work on a programme to investigate action of drugs and drug metabolites on schistosomes maintained in vitro. He will be required to conduct experiments using novel ultrasonic instrumentation, and will work closely with a counterpart in the Bio-Engineering and Medical Physics Unit of the University of Livernool. and Medi Liverpool.

The post is initially for 1 year from February 1, 1975. There is a possibility of registration for a higher degree.

Salary Range: £1,761 to £2,019.

Apply to: Professor H. M. Gilles, Department of Tropical Medicine, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool L3 5QA.

#### M.R.C. CLINICAL RESEARCH CENTRE. (Northwick Park Hospital), Watford Road, Harrow, Middlesex, HA1 3UJ.

Harrow, Middlesex, HAI 3UJ.

TECHNICIAN with H.N.C. or equivalent in Chemistry or Biochemistry to work in a research group studying the biochemistry of inborn errors of metabolism. The work which will be largely concerned with the measurement of amino acids and oligosaccharides in body fluids offers good opportunities of experience in modern methods of automated ion exchange chromatography and gas chromatography. Previous experience with one or other of these techniques an advantage.

Ref. 123D/Z/A23

TECHNICIAN with A.I.M.L.T. or H.N.C. preferably with experience of serology, haematology or bacteriology to work in a laboratory concerned with the study of human immunological disease:

Ref. 118/2/4196

Ref. 118/2/4196

Salary within the range £1,860 to £2,835 plus £126 London Weighting and Threshold.

Application forms may be obtained from Mrs. J. Tucker-Bull. Please quote reference.

#### NATIONAL ORGAN MATCHING AND DISTRIBUTION SERVICE

AND DISTRIBUTION SERVICE

A vacancy exists in the National Organ Matching Service at the Regional Transfusion Centre, Southmead, Bristol, BS10 5ND, for a Science graduate (B.Sc.) with a training in, or good practical experience of computer programming.

The Service makes use of computers in several facets of its work and the appointee will be expected to play a major role in the rationalisation and development of this work. Candidates should therefore have a strong interest in development of information storage and retrieval systems for specialised medical data as well as for scientific analysis, The appointment will be, initially for a two year period and will then be subject to review.

Salary scale, Junior Scientific Officer, commen-

review.

Salary scale, Junior Scientific Officer, commencing at £1,689 rising to a maximum of £2,994.

Application forms and further details of the post may be obtained from the Administrative Officer at the above address. (2199)

#### UNIVERSITY OF OXFORD

Post-doctoral biochemist required to study structure of mammalian chromatin and its relation to genetic activity, financed by Medical Research

Applications and enquiries to Dr. J. M. Barry,
Department of Agricultural Science, University of
Oxford, (2228)

#### M.R.C. CLINICAL RESEARCH CENTRE.

(Northwick Park Hospital), WATFORD ROAD, HARROW, MIDDLESEX, HAI 3UÍ

The Division of Immunology (Head: Dr G. L. Asherson) seeks medical or scientific worker to continue studies on the actiology of immunodeficiency disease in a setting in which clinical and laboratory aspects can be combined.

combined.

Conditions of the appointment, which is superannuable, are similar to those at Universities and the starting salary will depend on experience, age and qualifications.

Application forms may be obtained from Mrs J. Tucker-Bull. Please quote ref. 118/1/4193. (2204)

#### M.R.C. CLINICAL RESEARCH CENTRE.

(Northwick Park Hospital), WATFORD ROAD, HARROW, MIDDLESEX, HA1 3UJ

JUNIOR TECHNICAL OFFICER required in

JUNIOR TECHNICAL OFFICER required in the Division of Communicable Diseases to take part in research on virus, mycoplasma and other infections. Major part of work concerns research on sexually transmitted diseases. Experience in microbiology would be useful. Ref. 108/2/4061.

The Division of Immunology require a JUNIOR TECHNICAL OFFICER/TECHNICAL OFFICER and TECHNICIAN with experience in immuno-chemistry or tissue culture to work with a scientist on immunological problems in humans, Ref. 118/2/A21.

Oualifications: TO: HNC or relevant decree.

Qualifications:- JTO: HNC or relevant degree.
Technician: AIMLT, HNC or relevant degree.

Salary within the range of £1,875 to £2,718 plus Threshold increases.

Application forms may be obtained from Mrs. J. Tucker-Bull. Please quote ref. (2203)

#### RHODES UNIVERSITY GRAHAMSTOWN SOUTH AFRICA

Applications are invited for the post of LECTURER IN PHARMACEUTICS

in the School of Pharmaceutical Sciences from as early a date as possible.

The salary scale is R6,300 by 360 to R9,180 per annum. (Note: £1 sterling=approximately R1.60c).

A vacation savings bonus is payable and the successful applicant will become a member of the University's pension and medical aid schemes.

Applicants should hold a Master's or Ph.D. degree in Pharmaceutics.

Full particulars relating to the post and staff benefits together with application forms, may be obtained from the Registrar, Rhodes University, P.O. Box 94, Grahamstown, 6140, South Africa, to whom completed applications with copies of recent testimonials and a photograph, should be sent by January 18, 1975. (2223)

# **Experimental Officer**

### -Parasitology Project

You would have responsibility for running a unit involved in isolating, identifying and multiplying up a whole range of coccidia in connection with a coccidiosis chemotherapy programme. This work requires critical judgement plus an ability to plan a complex series of operations well ahead, and could suit someone with HNC or similar qualifications. For a more experienced candidate - having a biochemical qualification - there would be ample opportunity of studying biochemical problems associated with drug activity and drug-resistance.

# **Experimental Officer**

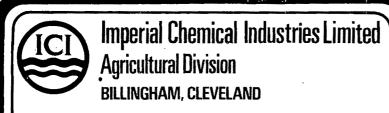

## Obesity Project

This position requires a graduate with a degree of Biochemistry/Physiology to join a laboratory concerned with the identification and development and testing of drugs for use in obesity. A further position exists in this unit for someone of HNC standard to do similar work.

Pharmaceuticals Division has interests in a wide range of human and veterinary medicine and offers modern laboratory facilities set in pleasant parkland, and competitive salaries. The Division is located close to the Peak District and within easy reach of Manchester. A wide range of reasonably priced housing is available in the area.

Please write giving details of age, qualifications and experience and research interests to:

M. F. Losse, Personnel Officer ICI Pharmaceuticals Division Mereside, Alderley Park Macclesfield, Cheshire.

# **Expansion in Biotechnology**

Agricultural Division of Imperial Chemical Industries Limited at Billingham, has an established and successful group engaged in biological research which. since its inception six years ago, has created the ICI Protein Process, an enzyme process and a novel effluent treatment system. The Division now wishes to expand its efforts in biotechnology.

This expansion will involve the creation of additional research project teams concerned with a variety of biological processes. These will include exploratory research directed towards quite new biological ventures, as well as the extension of our single cell protein technology to new proteins and the development of our interests in enzymology. Vacancies exist for

## MICROBIOLOGISTS, MICROBIAL BIOCHEMISTS, MICROBIAL PHYSIOLOGISTS & **BIOCHEMICAL ENGINEERS**

We wish to recruit PhD's and first degree graduates in these disciplines. Successful applicants would be expected to work in multi-disciplinary project teams and be responsible for planning and reporting their own research work.

The Company operates House Purchase, Profit Sharing and Contributory Pension Scheme and offers financial assistance towards removal expenses for married men.

Write, giving brief details of age, qualifications and experience and quoting Reference N/1 to:

Mr M A J W Pegg, Personnel Department, Imperial Chemical Industries Limited, Agricultural Division, PO Box No 1, Billingham, Cleveland TS23 1LB.

(2224)

#### UNIVERSITY OF READING DEPARTMENT OF MICROBIOLOGY

TECHNICIAN required for the Virology section. Duties include preparation of materials for practical classes, assistance to research workers, general supervision of equipment and services and some handling of laboratory animals.

Knowledge of techniques used in Virology and Immunology an advantage. Salary in range £2,247 to £2,628 p.a. (Grade 4).

Apply stating, qualifications, names of two referees, quoting ref: TN100, to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH

#### DEAN OF THE FACULTY OF SCIENCE

The newly-established Faculty of Science of the University of Regina requires a dean to consolidate programs and provide leadership. The University is seeking a person with an established reputation in research and with successful administrative experience. The Faculty contains six departments and 70 permanent faculty members. The Faculty offers three and four year undergraduate programs and graduate programs to the Ph.D. level.

Please apply to Mr. D. T. Lowery, University Secretary, University of Regina, Regina, Saskat-chewan, Canada, S4S 0A2. (2195)

#### UNIVERSITY OF ZAMBIA

UNIVERSITY OF ZAMBIA

Applications are invited for 3 posts of READER/SENIOR LECTURER/LECTURER IN DEPARTMENT OF GEOGRAPHY in the School of Education. Candidates must have specialist interests in one or more of the following:—Cultural Geography; Climatology; Quantitative Techniques; Cartography; Air-Photo Interpretation; Regional Planning; Population Geography; Land Resource Analysis. Ability to offer a course in regional geography would be advantageous. Salary scales: Reader K6,800 p.a. K5,600 to K6,600 p.a. K4,000 to K5,400 p.a. (£1 sterling=K1.49). The British Government may supplement salaries of all married appointees in range £516 to £1,026 p.a. (sterling) or supplement salaries of single appointees to the levels of Schior Lecturer and Reader in range £78 to £126 p.a. (sterling) (normally free of all tax) and provide children's education allowances and holiday visit passages. This supplementation is unlikely to be provided to single appointees to Lecturer level. Family passages; various allowances; superannuation and medical aid schemes; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than January 10, 1975 to the Registrar, University of Zambia, P.O. Box 2379, Lusaka, Zambia. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, WIP ODT. Further particulars may be obtained from either address.

#### UNIVERSITY OF CAMBRIDGE INSTITUTE OF ASTRONOMY THEORETICAL ASTRONOMY

Applications are invited for three research positions at the Institute of Astronomy, which will be available for two years, commencing October 1975. Appointments will be made on the appropriate university scale, currently £2,580 to £3,636 plus threshold payments plus F.S.S.U. benefits, to be reviewed by October 1975. The posts are at post-doctoral level for research in any aspects of theoretical astronomy, and are supported by an S.R.C. grant to Professor Martin

Candidates should apply by letter, giving a full curriculum vitae and the names of two referees. Applications should be sent to The Secretary, Institute of Astronomy, Madingley Road, Cambridge CB3 0HA to arrive by February 15, 1975.

TRANSLATORS (from Russian) and TRANSLA-TION EDITORS, freelance, Control, metering, Lasers, Holography wanted. Box.

#### LOTHIAN HEALTH BOARD

#### METABOLIC UNIT— Western General Hospital, Edinburgh

Applications are invited for the appointment of a SENIOR GRADE BIOCHEMIST in the above Unit which is concerned with the management of and research into endocrine and metabolic disorders. Previous experience in the subject is necessary. Suitable candidates may register for a higher degree and may take part in the M.C.B. training programme run by the Departments of Clinical Chemistry. Salary will be on the scale £3,345 to £4,377. Threshold agreement in operation. Whitley Council conditions of service apply.

Applications, quoting the names and addresses of two referees, should be lodged not later than January 25, 1975 with the Secretary, Lothian Health Board, 11 Drumsheugh Gar-Health Board, 11 Drumsheugh Gardens, Edinburgh, EH3 7QQ. Further particulars may be obtained, or a visit arranged, by contacting Professor J. A. Strong, University Department of Medicine, Western General Hospital, Crewe Road, Edinburgh, EH4 2XU. Telephone: 031-332 2525 Ext. (2173) (2173)

#### UNIVERSITY OF STIRLING DEPARTMENT OF BIOLOGY

#### CHAIR OF ANIMAL BIOLOGY

The University of Stirling invites applications for the Chair of Animal Biology which falls vacant on January 1, 1975. Applicants should be active experimental zoologists working with whole organisms and preferably with an interest in aquatic studies.

Applications together with the names of three referees, should be sent before January 20, 1975 to the Secretary (Na), University of Stirling FK9 4LA from whom further particulars may be obtained.

#### MOUNT ALLISON UNIVERSITY Sackville, N. B., Canada

invites applications for the position of Professor or Associate Professor in its Biology Department effective July 1, 1975. Ph.D. and/or established reputation preferably in Physiology and/or Ecology required. Some administrative experience is desirable. The appointee will be involved in under-

graduate teaching and research.

Apply to Professor D. S. Fensom, Head, Department of Biology, Mount Allison University, Sackville, N.B., Canada. (2190)

#### DEPARTMENT OF PHYSICS UNIVERSITY OF ALBERTA ELECTRONMICROSCOPIST

Applications are invited for an Assistant Professor in the area of Electronmicroscopist. Exceptional candidates in other areas of condensed state physics will be considered. The condensed state group at the University of Alberta consists of eight members in a Physics Department of forty-two faculty members.

The effective date of appointment is April 1, 1975. The closing date for applications is February 1, 1975.

Send vitage list of publications

1, 1975.
Send vitae, list of publications, and names of three referees to:
Dr J. T. Sample
Chairman Department of Physics
University of Alberta
Edmonton, Alberta, T6G 2E1 (X1911)

#### UNIVERSITY OF ALBERTA FACULTY OF SCIENCE DEPARTMENT OF LINGUISTICS

Applications are invited for an Assistant Professorship in Experimental Phonetics, commencing July 1, 1975. Salary range \$13,440 to \$17,611 for 1974-75.

The department's terms of reference are to conduct research and teach in the field of experimental linguistics with some responsibility for university service teaching in general linguistics. Preference will be given to a candidate with special research interests in the physiology of speech perception or speech production with ability to teach service courses in general linguistics. The Ph.D. is essential.

For further information, write to Professor C. I. J. M. Stuart, Head, Department of Linguistics, University of Alberta, Edmonton, Alberta, Canada T6G 2H1. (2180)

#### UNIVERSITY OF THE WEST INDIES TRINIDAD

TRINIDAD

Applications are invited for (a) LECTURESHIP or (b) ASSISTANT LECTURESHIP IN INORGANIC CHEMISTRY in the Department of Chemistry. An interest in modern analytical chemistry would be an additional qualification. Salary scales: (a) TT\$13,200 to TT\$20,904 p.a. Assistant Lecturer TT\$10,716 to TT\$11,748 p.a. (£1 sterling=TT\$4.8). F.S.S.U. Unfurnished accommodation for maximum of three years at rental of 10% of salary, thereafter 20% of salary payable in lieu of housing. Family passages. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, as soon as possible, to the Secretary, University of the West Indies, St. Augustine, Trinidad. Further particulars will be sent to all applicants. (2232)

#### BIOLOGIST

Graduate required to assist on Genetics Abstracts. The position would involve indexing, proof-reading and abstracting. Starting salary £1,770 p.a. Applications to Dr. E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG. Quote Ref. G1. G1. (2229)

# Opportunities **Overseas**

## Mexico

#### AGRICULTURAL CHEMIST

To conduct a post-graduate course on plant biochemistry with emphasis on agricultural applications and to initiate and supervise research programmes for post-graduate, and final year under-graduate, students. Applicants must possess a degree in Chemistry, Agricultural Chemistry or Agriculture with at least 3 years teaching experience and some experience of research in the field of agricultural chemistry. Appointment for 1 to 2 years initially.

Salary in scale £3,500 to £6,000 p.a. plus a tax free overseas allowance in scale £430 to £1,115 p.a. Other benefits include free family passages, paid leave, children's education allowances, and free accommodation and medical attention. Superannuation rights may be preserved and all emoluments are paid by the British Government. Applicants should normally be citizens of, and permanently resident in, the United Kingdom.

For full details and an application form please apply giving age and brief details of qualifications and experience to :

Appointments Officer

#### Ministry of Overseas Development

Room 301 Eland House Stag Place London SWIE 5DH

(2197)

#### FELLOWSHIPS AND STUDENTSHIPS

#### DEPARTMENT OF EDUCATION **DUBLIN**

#### POSTDOCTORAL RESEARCH **FELLOWSHIPS**

Applications are invited for up to twelve Research Fellowships in Science (excluding Medical and Social Science) and Engineering tenable in any one of the following institutions in Ireland:—

University College, Dublin
University College, Cork
University College, Galway
Trinity College, Dublin
An Foras Talúntais
(The Agricultural Institute),
The Institute for Industrial
Research and Standards.

Research and Standards.

The Fellowships will be tenable for two years with the possibility of extension for a third year.

Applicants should hold a Ph.D. degree or have equivalent research experience or, in the case of engineers or technologists, suitable industrial experience. Candidates should not be over 30 years of age; preferably they should be under 28e

Appointments will be effective not earlier than October 1, 1975. Salary will normally be £2,269 to £2,597 per annum; awards up to £3,061 may be made to engineers and technologists whose industrial experience or other special circumstances warrant!

Full particulars may be obtained from the Secretary, Department of Education (Headquarters Section), Marlboro' Street, Dublin 1. The latest date for receipt by the Department of completed application forms is February 10, 1975. (2174)

#### UNIVERSITY OF ADELAIDE POSTDOCTORAL RESEARCH **FELLOWSHIPS**

The University will award a limited number of Postdoctoral Research Fellowships in 1975. Vacancies exist in most of the Humanities, Social Sciences, Medical and Dental Departments; in the Departments of Agricultural Biochemistry and Soil Science, Animal Physiology, Biochemistry, Electrical Engineering, Architecture and Town Planning, and Statistics; and for research under the direction of Professor J. P. Quirk, F.A.A., Director of the Waite Agricultural Research Institute on the surface chemistry of oxides or pore sizes in gels in relation to soil structure

THE NORMAL AGE LIMIT is 20 warms.

THE NORMAL AGE LIMIT is 30 years, and preference will be given to applicants who have qualified for the degree of Doctor of Philosophy or its equivalent within the last three years either elsewhere in Australia or in an overseas country. Tenure will be for two years, with the possibility of extension for a third year.

SALARY SCALE: \$A7,545 to 7,837 to 8,129 to 8,420 to 8,711 (No superannuation provision), Particulars of provisions for travel to and from Adelaide, and other conditions of appointment, are available on request.

APPLICATIONS in triplicate must be made on the special forms obtainable, with the conditions of appointment, from the Registrar, The University of Adelaide, G.P.O. Box 498, Adelaide, South Australia 5001. Applications must be lodged with the Registrar by January 31, 1975. (2193)

#### APPOINTMENTS VACANT

# **PUBLIC** SERVICE

# SOUTH AUSTRALIA

# **Palynologist** Class 1

# **Mines Department**

Salary Limits: \$A7,204/10,008 per annum

#### **Duties**

Responsible to the Senior Palynologist for laboratory and field palynological studies related to the activities of the Geological Survey of South Australia.

#### Qualifications

A university degree or its equivalent with a major in geology is a minimum requirement, but a higher degree is preferred. Some experience in Late Palaeczoic and Mesozoic palynology would be an advantage.

Applications including full name, address, date of birth and details of war service, if any, for the position set out above, marked confidential and addressed to: The Director of Mines, Mines Department, 169 Rundle. Street. P.O. Box 38, Rundle Street Post Office, Adelaide, 5000 (Telephone 223 0461) will be received until and including January 10, 1975.

#### FELLOWSHIPS AND **STUDENTSHIPS**

#### UNIVERSITY OF STRATHCLYDE

Applications are invited for an S.R.C. POST-DOCTORAL FELLOW in the Artificial Organs Division of the BIOENGINEERING UNIT to work on the development of artificial lungs which produce convective fluid mixing for gas transfer augmentation. Applicants should have a Pure or Applied Physics, Chemical or Mechanical Engineering or Chemical Technology background. The studies will involve the analysis and evaluation of problems in gas dynamics, mass transfer and blood gas measurements. Experience in any of these areas would be advantageous.

these areas would be advantageous.

Appointment for three years commencing as soon as possible. Starting salary £2,580 per annum plus threshold payments. P.S.S.U. benefits.

Applications (quoting R43/74) including curriculum vitae and names of two referees to Professor J. P. Paul, Bioengineering Unit, Wolfson Centre, University of Strathclyde, 106 Rottenrow, Glasgow, G4 0NW. (2198)

#### THE UNIVERSITY OF MANCHESTER POSTDOCTORAL RESEARCH FELLOW IN OCCUPATIONAL HEALTH

Applications invited for a Research Fellowship Applications invited for a Research Fellowship from microbiologists to work on the aetiology of byssinosis. Appointment for three years. Initial salary up to £2,300 p.a. The work will involve travel to the Lancashire cotton mills. Further particulars and application forms (returnable by January 3, 1975) from the Registrar, The University, Manchester M13 9PL. Quote ref: 250/74/N.

(2217)

#### UNIVERSITY OF SUSSEX RESEARCH FELLOW

HISTORY AND SOCIAL STUDIES OF SCIENCE

OF SCIENCE

Applications are invited from graduates interested in the social history of modern science preferably with experience of archival research, for the position of Research Fellow in this Division. The Fellow will be appointed specifically to organize, catalogue and list the collected papers of J. G. Crowther, the science journalist. The work will involve materials concerning scientific journalism, science and government, and the "social relations of science" since 1918. The successful Fellow will commence work as soon as possible. The appointment will be renewable for a second year, on the scale £2,118 to £3,285 plus Threshold and F.S.S.U. benefits.

Application forms are available from the Secretary of Science, Science Office, University of Sussex, Falmer, BRIGHTON, Sussex to whom applications should be submitted no later than January 15, 1975. (2230)

#### WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales)

K.R.U.F. INSTITUTE OF RENAL DISEASE, ROYAL INFIRMARY, CARDIFF.

#### POSTGRADUATE STUDENTSHIP

A graduate in organic chemistry is required to participate in an ongoing study of the metabolism of immunosuppressive drugs in patients with kidney transplants. The successful applicant may be eligible to register for the Ph.D. Degree.

be eligible to register for the Ph.D. Degree.

Further particulars available from The Registrar Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN to whom application (in the form of a curriculum vitae with the names of two referees) should be made by December 31, 1974. (2200)

UNIVERSITY OF LEICESTER HISTORY AND SOCIAL RELATIONS OF SCIENCE

#### RESEARCH IN INFORMATION **STUDIES**

Applications are invited for participation in work, leading to a Ph.D., on the information content of research papers and their bibliographical control. Applicants should have, or should expect to obtain in the current academic session, a good degree in some area of science.

The Department of Education and Science is prepared this year to offer to suitable candidates a limited number of research studentships on a competitive basis. The value of these awards will be £880 p.a., commencing from October 1, 1975.

Prospective applicants should write for further details to Professor A. J. Meadows, University of Leicester, Leicester, LE1 7RH. (2207)

#### UNIVERSITY OF ABERDEEN UNIT FOR RESEARCH ON ADDICTIVE DRUGS

#### POSTDOCTORAL FELLOWSHIP

Applications are invited for above post supported by the Medical Research Council. Appointment is for two years with possible extension for third year. Salary in range £2,247 to £2,580 plus threshold payments. threshold payments.

Applicants who hold a Ph.D. in Organic Chemistry or Biochemistry are expected to take part in work in progress in the Unit concerned with the identification and synthesis of the endogenous compound with morphine-like actions recently discovered in the central nervous system. Facilities will be provided in the Unit and in the Department of Chemistry.

Further particulars from the Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by December 22, 1974. (2096)

#### THE UNIVERSITY OF **ADELAIDE**

WAITE AGRICULTURAL RESEARCH INSTITUTE

Applications are invited for appointment from the beginning of 1975 as a

#### POSTDOCTORAL FELLOW (ORGANIC CHEMIST)

in the Department of Plant Pathology. The appointment is funded from an Australian Research Grants Committee grant for up to three years.

SALARY SCALE: \$A7,545 to 292 (2) to 291 (2) to 8,711. Initial salary will be fixed in relation to qualifications and experience. No provision is made for superannuation.

FURTHER INFORMATION is available from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WCIH 0PF.

APPLICATIONS should reach the Registrar, G.P.O. Box 498, Adelaide, South Australia 5001, as soon as possible. (2181)

#### **GUY'S HOSPITAL** MEDICAL SCHOOL

#### Biochemistry and **Chemistry Department**

Applications are invited for an A.R.C. STUDENTSHIP

for a project involving the isolation properties of a novel steroidtransforming enzyme occurring in ani-mal testis. Applicants should have a good Honours degree in Biochemistry and will be expected to register for a Applications, including curriculum vitae and names and addresses of two referees, should be sent to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, from whom further particulars may be obtained. Please quote Ref. B.C.2.

#### FLINDERS UNIVERSITY OF SOUTH AUSTRALIA , POSTDOCTORAL RESEARCH **FELLOWSHIP**

Applications are invited for a Research Fellowship, tenable for three years, in the School of Physical Sciences. This position is supported by the Australian Research Grants Committee for crystallographic studies of fluorite-related com-

Applicants should have a Ph.D. degree in crystallography, and be familiar with crystallographic computing procedures. Experience in structure analysis on non-molecular crystals will be an advantage.

The appointment will be made in the salary range \$A8,184 to \$A12,331 according to qualifications and experience. Some allowance for travel and removal expenses will be made to the successful applicant.

Applications including full personal details of academic record, experience, and publications, together with the names of at least two referees, should be sent by December 31, 1974, to The Registrar, The Flinders University of South Australia, Bedford Park, South Australia 5042, from whom further details may be obtained.

Applicants are requested to arrange for referees reports to be sent directly before the closing date. (2183)

#### UNIVERSITY OF KENT AT CANTERBURY RESEARCH ASSOCIATE/ RESEARCH FELLOW IN BIOCHEMISTRY

post-doctoral or graduate research worker with qualifications in biochemistry or a related subject is required for work on nucleic acid and protein metabolism of malaria parasites and effects on drugs on these processes. A knowledge of protozoological techniques not expected. Appropriate training will be given. The appointment is supported from external funds, and is for one year with possible extension, from January 1, 1975 or as soon as possible thereafter. Salary in the range £1,782 to £2,580 for Research Associate (graduate) or £2,118 to £2,580 for Research Fellow (with Ph.D.) plus threshold payments.

Application forms and particulars from the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent. Please quote ref. A78/74. Closing date for applications December 31, 1974. (2187)

#### UNIVERSITY OF OXFORD

IN ASSOCIATION WITH CHRIST CHURCH, LADY MARGARET HALL, LINACRE, ST. EDMUND HALL, ST. HILDA'S AND ST. JOHN'S COLLEGES

#### I.B.M. RESEARCH FELLOWSHIPS

Applications are invited for four I.B.M. Research Fellowships tenable in any science department of the University for two years from October 1, 1975 in conjunction with Junior Research Fellowships at four of the following colleges: Christ Church, Linacre, St. Edmund Hall, St. John's (for a man); Lady Margaret Hall, St. Hilda's (for a woman).

woman).

The I.B.M. Research Fellowships are open to applicants who will have a doctorate (or will have submitted a doctoral thesis) by October 1, 1975 but who will not have had more than three years postdoctoral research experience by that date. At least one fellowship will be offered in the biological sciences and at least one in the physical sciences. Scale of stipends: £2,157 to £2,748 (plus threshold payments).

Application forms and further details are

threshold payments).

Application forms and further details are obtainable from the Secretary of Faculties (Ref. No. IBM/4), University Registry, Broad Street, Oxford OX1 3BD. Closing date for receipt of applications: January 14, 1975.

(2188)

#### LECTURES AND COURSES

CENTRE FOR POSTGRADUATE MEDICAL EDUCATION AND RESEARCH OF THE NORTH STAFFORDSHIRE INSTITUTE

#### UNIVERSITY OF KEELE SYMPOSIUM ON 'IMMUNE COMPLEX DISEASE'

to be held on FRIDAY FEBRUARY 21, 1975 at The North Staffordshire Medical Institute, Hartshill, Stoke-on-Trent. ST4 7NY. 10.15a.m. to 4p.m.

PROGRAMME "FORMATION AND FATE OF IMMUNE COMPLEXES"

Professor J. Hardwicke.

"METHODS OF DETECTION OF IMMUNE COMPLEXES" Dr J. Verrier-Jones.

"THE ROLE OF IMMUNODEFIENCY IN IMMUNE COMPLEX DISEASE" Dr D. K. Peters.

"THE INDUCTION OF INFLAMMATORY MEDIATORS BY IMMUNE COMPLEXES" Dr B. Kay.

"TOXOPLASMOSIS AS A MODEL OF IMMUNE COMPLEX DISEASE" Dr P. H. Lambert.

REGISTRATION FEE: £2.00

FLECTRO

(2214)

INTERNATIONAL SUMMER SCHOOL ON MOLECULAR AND CELL BIOLOGY

AUG.21-SEPT. 3, 1975 ISLAND OF SPETSAI, GREECE

#### THE MOLECULAR BIOLOGY OF ANIMAL VIRUSES

The school, sponsored by NATO and EMBO, will be suitable for predoctoral students and for postdoctoral workers in related fields.

Programme:-Lectures and discussions English will cover the following topics:

- (1) Basic molecular biology with emphasis on the comparison of prokaryotes and eukaryotes.
- (2) Structure and life cycle of bacteriophage  $(\lambda \text{ and } Q\beta).$
- (3) Structure, life cycle and biological effects of animal viruses (especially polio and DNA and RNA tumour viruses)

Applications should reach Professor B. F. C. Clark, Summer School Secretary, Department of Chemistry, Arhus Universitet, Langelandsgade 140, DK 8000 Arhus C, Denmark, as soon as possible (not later than May 15, 1975). They should contain a curriculum vitae, including the applicant's scientific background and interests, and one letter of recommendation.

Further details can be obtained from the above address or other members of the Organizing Com-

Organizing Committee: M. S. Bretscher (U.K.), B. F. C. Clark (Denmark), A. E. Evangelopoulos (Greece) and A. E. Smith (U.K.). (2213)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

AL POSTGRADUATE MEDICAL SCHOOL (UNIVERSITY OF LONDON)

#### M.Sc. in Medical Microbiology

Advanced academic and practical training, extending over two academic years, in bacteriology, virology, immunology, mycology, microbial genetics, medical protozoology, helminthology and entomology, as applied to clinical medicine and to preventive and community medicine, is provided through a new intercollegiate course of study for a University of London degree, replacing the Dip. Bact.

The first year will be spent at the two Schools of the University followed by a second year at a recognised laboratory. Candidates with satisfactory evidence of prior supervised practical training may be exempted from the second year of study.

The course is open to medical, dental and veterinary practitioners, graduates in science or pharmacy and other suitably qualified students.

A limited number of bursaries at Senior Registrar salary scales and Medical Research Council awards may be available to suitably qualified British subjects resident in the United Kingdom.

Closing date for applications: April 15, 1975.

Further particulars may be obtained from the Registrar, London School Hygiene and Tropical Medicine, Keppel Street, London, WC1E 7HT or the Secretary, Royal Postgraduate Medical School, Du Cane Road, London, W.12. (2194)

SYMPOSIUM

#### FOR SALE AND WANTED

## EMBO SYMPOSIUM 1975 DEVELOPMENTAL GENETICS

Hirschhorn-Heidelberg, April 30 - May 3 inclusive, 1975

Invited speakers will include:

M. Ashburner (U.K.), W. Beermann (Germany), A. Garcia Bellido (Spain), S. Benzer (U.S.A.), E. Bradbury (U.K.), S. Brenner (U.K.), A. Chovnick (U.S.A.), F. Crick (U.K.), E. Davidson (U.S.A.), W. Gehring (Switzerland), A. Gierer (Germany), F. Gros (France), F. Jacob (France), R. Kornberg (U.K.), P. Lawrence (U.K.), N. Ringertz (Sweden), K. Sander (Germany), P. Sengel (France), D. Suzuki (Canada), A. Tissières (Switzerland), L. Wolpert (U.K.), D. Yaffe (Israel).

Applications should reach J. Tooze, Executive Secretary, European Molecular Biology Organisation, 6900 Heidelberg, Postfach 1022.40, West Germany, before January 31, 1975. They should include a curriculum vitae, and an indication of the applicant's scientific background and current interests. Applicants will be informed whether or not they can be accepted during March 1975. A registration fee of 40 DM will be charged. Accommodation in Hirschhorn (15 DM to 30 DM per night) will be arranged by the Symposium Secretariat but participants will be responsible for their living and travel expenses. A small number of fellowships are available which will be awarded by the Organising Committee to young participants unable to obtain other sources of support. Persons wishing to compete for these few fellowships should so indicate in their letter of application.

The Organising Committee:

M. L. Birnstiel, S. Brenner, H. Bujard, A. Gierer, F. Gros, A. Monroy (Chairmau), N. Ringertz, J. Tooze (Secretary) (2179)

#### **BIOLOGICAL REVIEWS**

Availability of Back Numbers

All parts of Biological Reviews are available from the Cambridge Philosophical Society, Bene't Street, Cambridge, England, at the following prices:—

Vols 1-49 £8 per volume (£2.60 per part) Vol. 50- £10 per volume (£3 per part)

The following discounts are allowed:—
Orders of 2 to 5 volumes 5 per cent.

,, ,, 6 to 10 ,, 10 per cent.

,, ,, 11 to 20 ,, 15 per cent. ,, ,, over 20 ,, 25 per cent.

These discounts apply until March 1976, (2085)

#### WANTED

Books etc., on algae, especially diatoms. M. H. Winfield, 2 Hemming Close, Totton, Southampton, (2216)

# **BORIC ACID GELS**

## for the column chromatographic separation of sugars and nucleic acide

18,445-4 Boric acid gel, particle size 0.1 - 0.4mm. 30ml \$75.00

18,518-3 Boric acid gel, particle size <0.1mm. 30ml \$150.00 Boric Acid Gels are cross-linked polymers insoluble in water and organic solvents. They are prepared by the cross-linking copolymerization of dihydroxyborylanilino-substituted methacrylic acid with 1,4-butanediol dimethacrylate.

These gels serve as useful packing material for the column chromatographic separation of mixtures whose components form complexes of varying stability with boric acid. Complex formation is dependent upon pH and molarity of the buffer used.

The separation of mono- and oligosaccharides,<sup>2</sup> ribonucleosides-deoxyribonucleosides,<sup>1</sup> oligonucleotides<sup>3</sup> and t-RNA has been reported.

Boric Acid Gels may be used for preparative as well as analytical procedures, and are available in two porosities.

# Be bold, Mr Varley

MR Eric Varley took over as Britain's Secretary of State for Energy in an almost new government department nine months ago. He had much goodwill behind him as he struggled to absorb the complexities of the nuclear reactor'issues and to negotiate the political and industrial minefield of establishing the government's role in the exploitation of North Sea oil. His decisions on these thorny subjects have been tolerably well received. Alas, while he was coping with the issues of energy in the middle distance, his mind seems to have wandered from the ghastly problems of energy for the present. As a result it has taken nine months for anything of substance to emerge from the Department of Energy on the saving of fuel, and more particularly oil. And what has emerged is modest in the extreme:

- Oil price increases to bear more on the motorist: an extra 8p on a gallon is expected soon.
- Speed limits on roads other than motorways to be reduced.
- Buildings (other than homes) to be maintained at not more than 20° C.
- Improvements in thermal insulation standards for new houses.
- Loans to industry for energy-saving investment—up to a national total of £3 million a year.

None of this is likely to strike terror in the hearts of oil producers. Mr Varley eventually hopes to cut energy consumption by 10% but first estimates are that this package will save only 2%. Drivers on Britain's quaint single carriageway roads would be hard pressed to find stretches where they could exceed the new speed limit of 50 miles an hour. So we must assume that there are other more significant ideas in the pipeline.

The regrettable thing is that it has taken so long to get this short distance. Mr Varley has been gathering around him an Advisory Council on Energy Conservation -a surprisingly lengthy process considering the urgency of the problem—and he has had the benefit of the Think Tank's gratuitous advice this last summer. Yet the measures proposed could have been put together on the back of an envelope the day he arrived in his new office. What is more, nine months ago the mood of the nation was such that tough measures, already imposed in some cases last winter, would have been acceptable as long term propositions. Psychologically, Britain was prepared to live with some austerity. But such constraints as there had been were lifted, presumably for supposed political gain, and by midsummer the man-in-the-street's perception of the energy crisis was that a saving was no longer necessary. Not only the man-in-the-street. A high ranking civil servant in the Department of Energy admitted that the only permanent change in his behaviour as a result of last winter's crisis was that he now turned the light off in his railway compartment when he got off the train. It is

doubtful whether the new measures, which are clearly meant to have as much of a psychological as a physical impact, will restore the lost desire to conserve. What is more, there is almost nothing in Mr Varley's package to encourage industry, the big consumer, to economise.

What is needed is some full blooded government intervention. Whether it takes the form of rationing (and surely the Think Tank could with profit be set to develop a fairly sophisticated scheme for discouraging waste) a massive publicity campaign, jawboning of industrial chiefs or substantial price rises, there are ample opportunities for the government to move fairly deeply into the conservation business. To take one example, such propaganda as the government and nationalised industries have produced so far has seemed unbelievably halfhearted. Discreet advertisements in newspapers will persuade nobody. An enormous effort to raise national consciousness is called for, and this will need a large budget and much imagination. As a result of it, the general public might even end up appreciating solutions of the thermal diffusion equation--more than many scientists do at present. And perhaps someone will develop cheap continuously recording thermometers and other cost-monitoring devices.

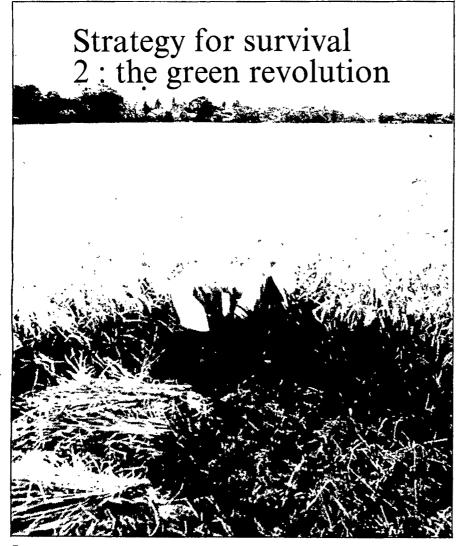

Ultimately, the government will have to face up to the central message of the energy crisis—that our way of life will have to change if Britain is to remain solvent. The same is true, of course, of all other countries similarly afflicted, but Britain will be the first to suffer if radical measures are not taken soon. It is strange that an external military threat would be perceived immediately and the public called upon to make sacrifices, whereas an economic threat is deemed unsuitable material with which to go to the country and ask for belt-tightening. Mr Varley might be pleasantly surprised by the response if he chanced his arm considerably more.

## A hundred years ago

THE process of polishing the lens of the mirror of the great telescope is going on at the French National Observatory by M. Martin. The diameter of the lens is 120 centimetres, and the polisher is a disc of 40 centimetres. The number of men engaged on the polishing is six. They are obliged to stop frequently on account of the great weight of the polisher. An observer placed on the top of the Observatory, at a distance equal to half the focal distance, superintends the polishing process, watching if the image of a light which is placed in a proper position is reflected with sufficient exactness by the mirror below.

From Nature, 11, 154, December 24, 1874.

David Spurgeon looks at a report soon to be published on what the farmers at the grass roots really feel about the Green Revolution.

Although in simple terms of production gains the Green Revolution has been an undoubted success, it has produced a harvest of reproach as well as praise. Critics have maintained that the introduction of the new high yielding varieties of wheat and rice together with the necessary package of technological practices has helped the rich get richer while the poor get poorer. They predicted that it would lead to the mechanisation of farms, reduction of opportunities for labour, concentration of land holdings and other factors which would increase inequities between rich and poor. All this was said without much in the way of factual support.

Now, at last, some real evidence is beginning to come in from the fields and farms of Asia. It appears in the results—soon to be published—of studies of 2,428 rice farms in 36 villages located in 14 separate areas of six Asian countries.

The research, funded by Canada's International Development Research Centre and carried out through the

International Rice Research Institute and a number of Asian institutions, was to determine just what changes had occurred in the wake of the introduction of the new rice technology. Answers were sought to such questions as: How extensively have the new varieties been accepted? Who is benefiting from the new technology, and in what way? How has the new technology affected employment? What have been the effects on social structure? And what are the major obstacles to further growth in rice production?

One major finding, in case anybody was still in doubt, was that the Asian rice farmer is not a stubborn traditionalist thoroughly resistant to change. Certainly he responded to innovation in a way that would minimise his risk, but respond he did: in 29 of 32 irrigated villages, 90% or more of the farmers reported that they had at least tried the modern varieties (which as used here means varieties introduced since 1965). Adoption rates vary from country to country, but in Pakistan,

for example, the area planted with the new rice varieties was 42% of the total only five years after their introduction into that country.

Another important finding was that both family and hired labour increased (and not the reverse, as predicted) in all of the study sites except in two Pakistan villages, where practically no labour changes were reported. This was so despite the adoption of the tractor in several places. Malaysian villages had the highest proportion of those taking on tractors, but pre-harvest labour decreased there nonetheless. In fact, the villages where labour-saving technology had been most widely adopted after introduction of the new varieties also reported the largest number of farmers who had increased their employment of family and hired labour. Apparently any savings in labour were more than offset by the labour requirements of the technology itself. And the introduction of the new varieties seems to have provided more, rather than less, employment to landless farm labourers.

On the question of increased income from higher yields the evidence varies. Income definitely increased for some farmers: in one area of the Philippines, the value of the farmer's harvest in both wet and dry seasons was almost three times what it was before introduction of the new varieties. Costs of production also increased, however, because more fertilisers and pesticides are required for the new varieties. Even then, farmers' incomes were often greater than they had been.

Yet, subjectively, many farmers did not see themselves as any better off. One researcher pointed out that this was partly because farmers and their families had eaten more rice themselves since the introduction of the new varieties while not seeing this as a form of profit, which of course it is. Another suggested that previous losses had left farmers with long-standing debts that could not be entirely offset by a single season's gains. Several researchers reported specific economic gains as a result of the new varieties and detailed how the gains had been spent.

Consumer goods figured high among purchases made by the successful farmers. These included bicycles and radios, sewing machines, house furnishings and farm implements. Many spent more on food and education than they had before, whereas others paid off debts with their increased profits.

Not all farmers felt the same way about their status after the introduction of the new varieties. Many saw themselves as better off but a few even thought they were in a worse situation.

The views of the researchers also differed. One report, from India, seemed to confirm the critics' opinions.

It maintained that "the new technology helped to tighten the grip of the big farmer on rural economy" and that, although there was no firm evidence of deterioration in living standards of small farmers, small tenants and labourers, "relative distribution of incomes appears to have worsened."

Yet in an analysis of the whole picture, Celia T. Castillo, of the University of the Philippines, said: "From the data, it is obvious that tenants and small farms are better off with modern than with local varieties as far as their own assessment of increase in rice profits and level of living is concerned. Of course, owner-operators and large farmers were much better off than tenants and small farmers. How else could it have been? It is truly asking for a miracle to expect that the new seeds would bring about social equality where centuries have failed to produce a dent on institutional rigidities."

Dr Castillo says emphasis on the relative gains made by the rich and poor farmers has led to a neglect of another issue-farmers' gains relative to where they were before the advent of the new technology. If one becomes preoccupied with the income distribution issue, one is left with the impression that tenants and small farmers would have been better off in terms of incomes and living standards if they had stuck with traditional varieties, she says. And if this were the case there would be no rationale for spreading the new seeds more widely. But it is not the case, according to the data.

In another analysis, Randolph Barker and Teresa Anden, of the International Rice Research Institute, state: "It is clear that a technology that requires more cash inputs will tend to reinforce this [income distribution] inequity in some of the study villages. One cannot, of course, expect technological innovations to correct serious inequities in access to and benefits from resources. The only mitigating step that can be taken is to attempt to reduce cash requirements, particularly for chemicals, by building more resistance and tolerance into the seed itself. Increasing emphasis is being given to this problem in rice research.

The necessity for such research was illustrated in both West Java and the Philippines. In the former, about half the wet season crop was destroyed by gall midge, and in the latter tungo virus caused similar damage. Farmers in Java noticed that attacks were more severe on the available new varieties, so they reverted to local ones, while in the Philippines resistant modern varieties were available—and were used.

Barker and Anden conclude, from the responses of farmers to a question about their preferences, that local varieties will remain popular in some areas until modern ones are developed that are suitable to local environmental conditions, or until the strong price preference for local varieties changes. They also note that government policy has been a significant factor in determining the speed with which the new varieties have become available and accepted, if such policy has influenced price and availability.

Dr Castillo pointed to another notable finding of the study: "Although high yield capacity is the characteristic most associated with the new varieties, in many villages where adoption has taken place, their yields did not exceed those of the local varieties; they were adopted because of their shorter growing period and non-photoperiodism." Many farmers used the new varieties because they could provide two crops instead of one. This second crop sometimes replaced one of pulses and vegetables, however, and the impact of this on the protein-poor diet of the farm

family will have to be further analysed.

A clear need emerged for improvement of several factors if the full potential of the new varieties is to be achieved: availability of credit and the necessary infrastructure through which seeds, fentiliser and pesticides can be obtained; irrigation and flood control; and suitable government policies regarding price, information distribution,

and so on.

The study should provide a good factual base from which to consider not only what changes the new rice technology has made in Asia, but also what changes are needed for the future. Those involved in it consider, however, that an equally important result—if not a more important one—will be the strengthening of social science research in the region. In their eyes it is not just another research project; it is a device for developing a network of relationships among Asian social scientists concerned with similar problems.

Land preparation and harvest in the Philippines.

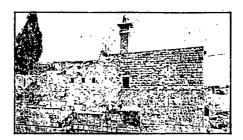

# international news

ISRAEL seems to have adapted the diplomatic 'leak' to suit the requirements of the Middle East confrontation. Appropriately for a nation which so reveres science and the academic tradition, a vague confirmation of the Israeli nuclear capability was made recently, not through a lobby's 'nark' sloping around the back door of the Knesset, but by the President, himself a scientist, in open discussion with a group of visiting science journalists.

Exactly what President Ephraim Katzir, former chief scientific adviser to the government, meant when he said that Israel could build a nuclear device if necessary "within a reasonable period of time" is open to a variety of interpretations. Nobody would be very surprised to learn that Israel had saved enough plutonium from its Frenchbuilt Dimona reactor to manufacture about 10 devices of 20 kilotons-that is, big enough to do to Cairo and Amman what was done to Nagasaki. Neither would it be big news to hear that the aviation industry was working on a delivery system and that, meanwhile, the odd bomber has been set aside for the job. (It's unnerving how many times a day you're told that a Volkswagen roof-rack or a fastish camel might serve as a last resort.)

Anyhow, given the speed with which recent Middle East wars have run their course, "within a reasonable period of time" is more likely to mean "we made a batch of components last year" than "we could manage from scratch in a couple of weeks". This much was already taken for granted.

The only real news was that it was Katzir who was laying it on the line and the following day, when journalists tried to telephone the tidings to editors on the continents of Europe and America, the censor tended to cut in on the call and impose a moratorium. The effect of this kind of reaction is. of course, counter-productive, because jaded editors pay rapt attention to stories which other people want to keep quiet, particularly when the other people are military censors. So when the good news was brought (as inevitably it would be from a purposebuilt junket for professional scribblers) it received an arguably inflated Press statement. Obligingly, an official clarification followed the next day, to the effect that what the President had meant to do was to stress the official line on nuclear arms. Katzir's office said he had been referring "to the general potential in Israel of scientists and general scientific-technological experience that, objectively, could be implemented if Israel so desired". The statement added that the President had simply "reiterated past pronouncements to the effect that Israel will not be the first to introduce nuclear weapons to the area".

Temple Mount, Jerusalem

# Problems in Israel

by John Hall and Peter Newmark

At this point interpretations diverge. The conspiracy theorists say that having gathered a fair sample of Western journalists who were searching for military implications in every science project they were shown, the titular head of state and founder of the country's major defence research centre is scarcely going to blurt out new information about the biggest state secret he knows. Neither is he the sort of character who needs to have his statements toned down by nervy 'official clarifications'. In other words it was all a fix. Katzir knew very well how his remarks would be read and the official correction was sufficiently ham-fisted to make no difference to the general interpretation that Israel was all set to go nuclear. The intervention of the censor, on this analysis, was all part of the act, just to make sure the story got page space.

The point of the exercise, on this •reading, was to spell out plainly to the Arab world that Israel's nuclear-bluff strategy was over at last. The Hebrew University's Middle East conflict scenario studies have shown that the country's intentionally ambiguous nuclear weapons policy has backfired. The idea was that if nobody really knew whether or not Israel had a bomb everybody would be cautious about attacking. You had one guess on the issue and you couldn't afford a fifty-fifty chance of error. In fact, according to the studies, the effect of the 'ambiguous' policy has been to increase the race by other Middle East countries to acquire nuclear weapons. There have also been two wars along the way. So the set-up was intended to say to the Arabs: "No more mystery. We'll use bombs if we need to", while at the same time avoiding international censure by broadcasting a softer official line.

The second interpretation? President Katzir, who was speaking freely and informally, didn't anticipate that every word he said would be subjected to a semantic analysis which allowed a newsstarved reporter to read in an unexceptional remark the story he'd been looking for all week.

• It is traditional for a journalist visiting a foreign land to draw his truisms from the mouths of anonymous taxi drivers, who encapsulate the wisdom of the ages and folkloric charm in a single aphorism which also happens to contain the kernel of the hack's thesis. As if to preserve one's fondest illusions our Rehovot driver settled behind the wheel and volunteered the information that the trouble with scientific research in Israel was that it contained too many chiefs and too few indians. Seventeen per cent of the working population of one million people were academics, and if some of the chiefs left their campuses and became indians in industry, then things would be so much the better, he added, warming to his subject. (Anyone wishing to establish bona fides is referred to Michael Fox, 3a David Shimoni Street, Rehovot.)

In confirmation of Mr Fox's assessment, Dr Eliezer Tal, Director of the National Council for Research and Development, also regretted that the country's research effort was top-heavy on basic work carried out in the universities, and getting more so with every year's intake of immigrants. (An average year's 35,000 arrivals include 350 scientists, and an influx of 600 scientists is expected from the Soviet-American deal to release Russian Jews.)

Research and development spending in Israel breaks down as follows: military, 45% of the total; university research (mainly basic) 30%; industrial, 12%; government laboratory work,

10%; others, 3%. Broadly, says Tal, the three main objectives of the government are to secure a better spin-off from the military work which consumes such a vast proportion of the budget, to look for ways in which the excessive amount of university research can be used to support industrial projects, and to encourage industry to buck up and get on with its own research programmes. To this end incentive programmes are under way which weigh the grant distribution system heavily in favour of the researcher who opts for applied work. Tal points to countries like Switzerland and Sweden as examples of top level industrial producers whose excellence reflects their disproportionately high spending on industrial research. It must be remarked, however, that they have thoroughly complacent taxi drivers.

• In a country whose development depends as much on water as on anything else, it is not surprising that the discovery of new sources is followed by ambitious plans. After the war of 1967, and following a combination of biblical clues and intelligence reports, a search for underground water in the occupied Sinai desert led to the discovery of a considerable reservoir. Carbon dating studies show that this water originated 20,000-30,000 years ago and is therefore unreplenishable fossil water. But according to Arie Issar, a hydrologist at the Ben-Gurion University of the Negev, sufficient water can be tapped to support the equivalent of 60 new settlements for 50 years. More precisely, he estimates that the output could be 50 million cubic metres a year.

The Desert Research Institute of the Ben-Gurion University, set up in 1973, has a substantial interest in this new water source. Situated at Sde Boker in the Negev Desert, 30 miles south of the main university campus in Beersheba, its scientists are undertaking a wide programme of desert research. They hope to be able to use the water to irrigate large areas of the Negev so that agricultural development can take

A combination of basic and applied research has been designed to tackle the problems that this project will have to solve. Apart from the general problems of establishing settlements in the desert and of making life bearable, or preferably attractive, for the settlers, there are more specific questions raised by the quality of the water. It has been found to be both warm (42° C) and somewhat brackish. The institute's scientists claim that the warmth may actually be an advantage when it comes to growing winter crops. The salinity is also unlikely to pose much problem since there are many crops that can cope with the salt levels involved. In addition it is hoped that a programme of plant breeding will yield other and better salt-resistant strains.

Another approach to persuading the desert to support more life than a few Bedouins is that of introducing alien vegetation which will grow even without irrigation. Two promising cases are jejoba, an American desert tree whose nuts are a source of high quality wax, and atriplex, an Australian fodder crop for grazing animals. Once the Negev is tamed, the planners see no end of exciting possibilities. There are promises, for example, of a series of safari parks teaming with African wild life. But right now it is not altogether clear when the promised water will flow into the area from the reservoirs.

• The decision of UNESCO to cut off aid to Israel was met with both sadness and bitterness in that country. Israel's president, Ephraim Katzir, felt that it was "the beginning of the destruction of civilised organisations" and expressed sorrow that politically motivated decisions, which were only to be expected in the UN itself had found their way into UNESCO affairs. To which sentiment the Director-General of UNESCO, Amadou Mbow, effectively replied in a statement that "the delegates to the general conference are government representatives. It is natural that the problems which perturb the world today should find an echo there".

In other words the oil monopoly and the political intricacies of the Middle East are justification for bringing sanctions to bear against the country which has done the most in that area in recent times for education, science and culture. For the alleged claim against Israel, that of endangering and disfiguring religious sites in the course of archaeological excavations in occupied Jerusalem, can not be taken very seriously. It is certainly a difficult job carrying out excavations in Jerusalem where every inch of land seems to be vied for by two or more religions, nowhere more so that at the disputed site outside the Western (Wailing) and Southern Walls of the Temple Mount. There is, however, next to no expert condemnation of the excavations so far undertaken there by the Archaeology Department of the Hebrew University, Jerusalem.

Ironically Israel has actually benefited financially from the UNESCO decision—the UNESCO contribution to the costs of the excavations was only a quarter of the sum paid into UNESCO funds by Israel. And in terms of participation in UNESCO, the position seems to be unchanged, in that Israel's request to join the organisation's European regional group has not been granted. Israelis are disappointed at the lack of reaction from the scientific community abroad but grimly resigned to their increasing isolation.

#### Universities in the not-so-red

British universities have been spared some of the ravages of inflation by the decision of Mr Prentice, Secretary of State for Education and Science, to mentation of the grant for 1974-75 to accepting students for 1975. about £21 million, roughly what the universities had expected for that year on the basis of the rise in costs during the quinquennium remains to be seen. 1973, which is how the government does its calculations.

gone up since then, so, although the future would have to take into account Chancellors and Principals (CVCP) increasing.

welcomed the announcement, as a help to the universities in their "grave" situation arising from the high continuing rate of inflation, they warn that substantial economies will continue.

The Secretary of State will soon be able to announce the level of grant for the financial years 1975-76 and 1976increase their recurrent grant by £15 77. Universities must know this decision million. This brings the total supple- soon say the CVCP as they are already

#### Visa for Voronel

Aleksandr Voronel, the Soviet physicist has received an exit visa for Israel.

In spite of official harassment, illicit Sunday seminars of scientists dismissed after applying for visas for Israel continued meeting during the Autumn in Moscow. On November 15, Voronel was told by the KGB that he could have permission to emigrate provided the seminars were discontinued. Voronel replied that he did not see the connection between his leaving the country and the seminars, which would stop only if the whole group were allowed to emigrate. Nevertheless even though the seminars had been continued in the interim, on December 11 Voronel received an exit visa valid until December 24.

Issued against the background be able to communicate with the of reports that various workers have operator through a built-in two-way contracted illnesses ranging from cancer to giddiness, kidney malfunctions, loss of memory and cramps after work
European Space Research Organisa
European Space Research Organisa
Space Research Organisaing for sustained periods with polyvinyl chloride and a jet fuel (MC77), the new law lists 125 substances and specifies the maximum allowable concentration of each to which workers may be exposed, averaged out over an eight hour day or a period of fifteen minutes. The permissible levels of about 80 of the substances have been lowered, some drastically, and new chemicals have been put on the list. Vinyl chloride used to be allowed in concentrations up to 20 p.p.m. The new level will be 1 p.p.m., the same as that set recently in the United States.

Other substances affected by the new law include arsenic, 20-30 kg of which is used daily in the making of glass and for which concentrations will be lowered from 0.5-0.05 mg per m<sup>3</sup>, and chromium salts. Used in the tanning of leather and as pigments in anti-rust paints, these will in future be allowed in concentrations of 0.05 mg instead of the present 0.1 mg per m<sup>3</sup>. The levels of various solvents (acetone, toluene, formaldehyde) have also been reduced, as have octane-raising additives in fuel.

The new law has been criticised at the Health Centre of Stockholm's Institute of Technology, where it has been argued that the new levels are merely repetitions of those now in force in the United Kingdom and the United States and reflect more a balance between economy and hygiene than any facts about the substances cancer-producing properties. In spite of this, the measure will be welcomed by those for whom it will mean safer working conditions.

#### ARC faces money shortages squarely

by Eleanor Lawrence

THE practical effects of the Rothschild Report are now being felt by the research councils generally and by none more so than the Agricultural Research Council (ARC). Introducing the Annual Report for 1973-74, the Secretary of the ARC, Dr W. M. Henderson, was inevitably concerned with the effects of the resulting White Paper on the distribution of government funds for agricultural research, making themselves felt as they do at a time when there is less money all round.

Since 1967-68, as Dr Henderson points out, the annual growth rate of the Soience Budget from the Department of Education and Science for all the research councils had fallen from 11.2% to 3.9% and the ARC's share has decreased from 12.2% to 4%. The source of the funds available to the ARC is also changing. In 1973-74, 59% of its budget came from the Science Budget, 23% from the Ministry of Agriculture, Fisheries and Food (MAFF) and 18% from the Department of Agriculture and Fisheries for Scotland (DAFS). The expected proportions in 1974-75 are only 38% from the Science Budget, 46% from MAFF and 16% from DAFS.

The ARC's present programme of work has fitted in with the requirements of MAFF, the 'customer', without too much upheaval and new commissions from the ministry are scheduled to begin next April. Dr Henderson had special praise for the work of the Joint Consultative Organisation, a body made up of representatives of the ministries, universities, the research council and its institutes and units, and the farming community, which was set up to recommend priorities for future work and to evaluate the existing programme.

The tight financial position implies that no new work can be undertaken by the ARC. Although there seems to be no immediate danger of drastic cuts in particular projects, a reduction in the work force seems inevitable. At the moment there is a moratorium on the filling of posts left vacant through retirement or resignation, but Dr Henderson emphasises that this is not a satisfactory answer. "We cannot," he said, "under any circumstances stop the recruitment of a due proportion of good young scientists". He could, however, give no clear indication how this was to be achieved.

One of the most frustrating restrictions will be the inability to inject the necessary money at the 'growing' points where an increase in funding would bring in the best returns.

# correspondence

#### **UNESCO** and Trieste

SIR,—Your leader of November 8 was critical of the line you thought the United Kingdom would be taking on the question of the International Centre for Theoretical Physics, Trieste, at the recent 18th General Conference of UNESCO, and attributed this probable attitude largely to Sir Harold Thompson personally.

Now that the General Conference is over, we would like to put on record that Sir Harold Thompson, as the British spokesman in the Science Commission of the General Conference, was representing the views of the Royal Society UNESCO Committee, endorsed by Her Majesty's Government. Britain was not critical of the achievement of the ICTP: indeed the British delegate praised the Centre and its Director. Nor was the United Kingdom delegation seeking the withdrawal of UNESCO funds to the ICTP in the forthcoming biennium; it voted for the budget for the basic sciences, including the full proposed provision for the Trieste Centre in 1975 and 1976.

Along with several other Member States, however, the United Kingdom delegation at the same time supported a resolution, passed unanimously at the 94th Session of the UNESCO Executive Board in May of this year, which stated that:—

"(The Executive Board)... Takes the view that Unesco's continued support to the International Centre for Theoretical Physics, Trieste, for the years 1975-76, is acceptable, but is of the opinion that Unesco's relations with and subvention to the Centre should be reexamined carefully in the light of Unesco's total support to basic sciences."

D. C. MARTIN A. B. COZENS

Royal Society UNESCO Committee, Ministry of Overseas Development, London, UK

#### Irrationalism and science

SIR,—I agree wholeheartedly with the comments of Martin Raff (Nature, December 6). I have been to a number of good conjuring shows in my time and I have invariably found that in a high proportion of the tricks I am not only unable to see how they were done, but I have been unable to understand how they could possibly have been done without an entirely unreasonable amount of joint conspiracy with mem-

bers of the audience. In no case has this led me to believe that novel mental powers were required.

If we were to believe that Mr Geller's achievements went beyond our scientific understanding in the ways that his supporters suggest, there are some very uncomfortable corollaries which have apparently been unnoticed. For example, if he can bend a fork from a distance he could presumably be able to do the smaller mechanical task of putting a kink in an artery.

I am not imputing any undesirable behaviour to Uri Geller, but if other less upright exponents of his art should appear, could they be trusted not to try this on people who were in their way? We are better now at looking for reliable evidence for such things than were the past believers in black magic or present believers in Juju, and could investigate properly the statistics of unexpected coronary thromboses or strokes among the known enemies in the past of suspected people. Having found a number of suspects for which the probability of chance gave P < 0.001, we should still have around one in a thousand who would be unjustly indicated as guilty. For further tests the extensive mediaeval literature on witchcraft should be re-examined.

I seem to remember a technique which consisted of throwing the suspect into a pond; if she sank she was innocent and received a Christian burial while if she floated she was dispatched with a silver bullet and buried with a stake through her heart at cross roads.

Since I think the whole suggestion of super-normal powers is nonsense, I am not myself bothered, but those who take the opposite view might well be needing to consider just what legislation would be necessary for dealing with a witch if their case should ever be proved.

#### Strong, attractive, vain . . .

SIR, — The recent contribution by Gribbin¹ suggests, inter alia, that there may be a significance in the titular characteristics of the Leo sub-group on the Nature editorial staff. This possibility of significance is given weight by McIntosh, who writes of those born under Leo: "The Sun rulership gives him a strong attractive personality and makes it easy for him to command loyalty from others. These qualities

make him a natural leader, and the sign has long been associated with kings and potentates". It should perhaps also be mentioned that, according to the same source, "The faults that sometimes afflict the Leonian are vanity, pomposity and greed for power".

In view of the fit between sub-group attainment and expectations, it is regrettable that further research, carried out in an institution similar to the one in which Gribbin works, has shown that the Pisces hypothesis does not hold water.

#### **Ghost authors**

SIR,—Ghost authors (*Nature*, December 6) are no new phenomenon. A good many years ago a paper by the late Professor Martin Rushton was published, giving after the author's name his qualification M.A.Cantab. Subsequently this was mistaken for a second author, and the reference "Rushton and Cantab" was a standing joke among dental research workers for some years. It found its way into at least one textbook.

#### Nullius in verba

SIR,—R. B. Cater's complaint (Nature. November 29) that 70.4% of all inquiries for a reprint spelt his name wrongly, is not as bad as be makes out.

It is a firm principle in science that the worth of any man's work is independent of that man's non-intellectual attributes, such as mere name. Far from displaying a lack of observational powers I would say that they are verifying the principle (and the motto of the Royal Society)—nullius in verba—on the words of no man.

Dr Cater would have had more cause for complaint if either (a) his work was disregarded because he was thought to be insignificant or (b) his work was accepted because his father was thought to have been a good scientist.

## Neuropharmacology of peptides

SEVERAL amino acids, such as glutamate, aspartate, glycine and gamma-aminobutyrate, have powerful excitatory or inhibitory effects on neuronal firing in the mammalian central nervous system. Recent findings have shown that certain peptides also have highly specific neuropharmacological actions, and it seems possible that some neurones may release peptides which have a neurotransmitter or modulatory role in the nervous system.

It has been known for some time that neurones in certain regions of the hypothalamus contain and release peptides with important endocrine functions. Thus neurones in the hypothalamus synthesise the hormones vasopressin and oxytocin which are released into the blood stream from the terminals of these cells in the posterior pituitary gland. Nicoll and Barker (Brain Res., 35, 501; 1971) found that vasopressin exerted potent inhibitory effects on the firing of neurones in the supraoptic nucleus, and suggested that vasopressin might be released by recurrent collateral fibres mediating inhibition of the neurosecretory cells. Vasopressin in low concentrations was also found to cause long lasting changes in pacemaker potential activity in a specific neurosecretory neurone of the land snail Otala lactea (Barker and Gainer, Science, 184, 1371; 1974). Other hypothalamic neurones secrete 'releasing factor' peptides into the portal circulation to the anterior pituitary and these peptides represent the final link whereby neural influences control the endocrine activity of this gland.

Recent findings suggest, however, that the neuropharmacological activity of certain hypothalamic releasing factor peptides may not be confined to the endocrine functions of the hypothalamic-pituitary system. The tripeptides TRH (thyrotropin releasing hormone) and MIF (melanocyte inhibitory hormone inhibitory factor) have a wide variety of behavioural effects in man and animals. In animals these peptides potentiate the psychomotor stimulant actions of Ldopa (Plotnikoff et al., Science, 178, 417; 1972) and enhance the behavioural excitation produced by a combination of tranylcypromine and L-tryptophan (Green and Grahame-Smith, Nature, 251, 524; 1974), and accelerate the rate of turnover of noradrenaline and dopamine in the brain (Friedman et al., Science, 182, 831; 1973; Keller et al., Nature, 248, 528; 1974). Several groups have claimed that TRH has transient mood elevating effects in depressed patients and in normal subjects (Prange et al., Lancet, i, 999; 1972; Tiwary et al., Lancet, ii, 1086; 1972; Wilson et al., Lancet, ii, 43; 1973; Wilson et al., Archs. gen. Psychiatr., 29, 15; 1973). The suggestion that TRH may have a role in controlling neuronal excitability in the central nervous system, apart from its endocrine function, is also supported by the recent report that more than two thirds of the total TRH in rat brain is located in brain regions outside the hypothalamus, with particularly high concentrations in certain septal and preoptic areas (Winokur and Utiger, Science, 185, 265; 1974; Brownstein et al., Science, 185, 267; 1974).

Another peptide with powerful neuropharmacological effects is the undecapeptide substance P, discovered by von Euler and Gaddum in 1931 in extracts of brain and small intestine (J. Physiol., Lond., 72, 74; 1931). The amino acid

sequence of substance P purified from bovine hypothalamus was reported by Chang et al. (Nature, 232, 85; 1971) and the synthetic material is now available. In this issue of Nature (page 734) Konishi and Otsuka show that substance P has a potent excitatory action on mammalian spinal cord motoneurones. They used an isolated spinal cord preparation from newborn rats, in which substances can be applied to the perfusion fluid in precisely controlled concentrations, and found that substance P was about 200 times more potent than the powerful excitant amino acid L-glutamate in causing a depolarisation of motoneurones. Substance P also facilitated monosynaptic spinal cord reflexes. In previous studies Konishi and Otsuka had shown (Brain Res., 65, 397; 1974) that substance P and the related peptides physalaemin and eledoisin were potent excitants of motoneurones in frog spinal cord, the latter compounds being 1,500-2,000 times more potent than L-glutamate. Takahashi et al. (Brain Research, 73, 59; 1974) also confirmed earlier reports that substance P is present normally in bovine dorsal root nerves, and that its concentration in these sensory nerves was 10-30 times higher than in the ventral root spinal motor nerve. These findings thus strongly support the view that substance P may be selectively concentrated in sensory nerves and that it could function as the transmitter substance released from sensory nerve terminals in the spinal cord, as suggested earlier by Lembeck (for review see Lembeck and Zetler, Int. Rev. Neurobiol., 4, 159; 1962). Substance P is also present in various regions of the brain, and in brain homogenates the peptide is highly localised in nerve terminal particles, or synaptosomes (Whittaker, Progr. Biopsys. molec. Biol., 15, 39; 1965). When applied iontophoretically from microelectrodes on to single neurones, in the cerebral cortex or cuneate nucleus, substance P has been found to be a powerful excitant of neuronal firing (Phillis and Limacher, Expl. Neurol., 43, 414; 1974; Krnjevic and Morris, Can. J. Physiol. Pharmac., 52. 736; 1974). The latter authors, however, found the actions of substance P to be slow in onset and longlasting, and suggest that the substance is unlikely to represent the quick acting transmitter released from sensory nerve terminals.

The possibility that 'peptidergic' neurones may exist, releasing peptide neurotransmitter substances, or that peptides may exert other long-term modulatory influences on neuronal function is one to delight the neuropharmacologist and the pharmaceutical industry. With modern techniques of peptide chemistry it should be possible to design and test a large number of structural analogues of the naturally occurring materials, and perhaps to develop neptides with highly selective neuropharmacological actions. For example, it may be possible to dissociate the behavioural and endocrine effects of substances such as TRH and MIF, or to obtain analogues of substance P that will penetrate more readily into the central nervous system from the circulation. If the initial promise is sustained, this seems likely to become an important new area for neuropharmacological research.

L. L. IVERSEN

#### Competition for laser fusion?

from a Correspondent

THE incident laser power needed to achieve a significant thermonuclear energy gain in a deuterium-tritium (DT) target which initially has a density near that of the solid state has been variously estimated to lie between 1013 and 3×1015 W; the lower power is appropriate to hollow spherical pellets seeded with materials having a nuclear charge greater than unity, and the higher power to pure, homogeneous spherical DT pellets. The predicted power needed to maximise thermonuclear gain from a given target depends not only on the sophistication and ingenuity of numerical or analytical models, but also on various physical assumptions; these may range from the technological, such as the inclusion of two-dimensional effects induced by small variations in incident light intensity or target symmetry, to the fundamental, such as a self-consistent treatment of non-linear laser-plasma phenomena. (For a good introduction to the subject, the reader is referred to review papers by J. Nuckolls, R. E. Kidder, K. A. Brueckner, R. L. Morse, and others, to be published in Laser Interaction and Related Plasma Phenomena, 3, edit. by H. Schwartz, Plenum Press.)

An interesting example of the interrelation between practical problems and more fundamental effects in laser fusion is afforded by recent radio-frequency and numerical experiments reported by Kim et al. (Phys. Rev. Lett., 33, 886; 1974), in which the trapping of radiofrequency electric fields within a density cavity, or 'caviton', has been demonstrated. Their experiment simulates the generation of a parametric instability which occurs when a non-uniform laserplasma is driven by a (pump) electric field directed parallel to the density gradient. Although this field component would be zero in an ideally symmetrical

spherical implosion, it may not be negligible in a practical experiment; the applied field is thus enhanced by linear, resonant conversion to electrostatic modes in regions near the critical density.

A wide range of other laser-plasma effects are also of interest. Consequently predictions of the laser energy needed for significant thermonuclear gain depend on the wavelength  $(\lambda)$  of the laser light. For example, Kidder estimated that, if core-corona decoupling is the limiting physical process in pure DT pellets, laser energy requirements range from 70 kJ (at  $\lambda = 0.265 \mu m$ ) to 3 MJ (at  $\lambda = 10.6 \mu m$ ), whilst Nuckolls computes that a 100 kJ, 1013 watt,  $\lambda = \frac{1}{2} \mu \dot{m}$  laser is required for useful power generation (invited paper given at VIII International Quantum Electronics Conference, San Francisco, June 1974). An economic DT fusion reactor thus requires lasers having energies significantly above those possible at present and with efficiencies of some 15% (Spalding, Energia Nucleare, 21, 176; 1974), although hybrid fusionfision energy schemes may lower the required laser efficiency (Horoshko, et al., Annals of Nuclear Science and Engineering, in the press). Probably for these reasons, Professor E. Teller recently told an audience at Stanford University that critical experiments in laser fusion may take a generation to complete (New Scientist, 64, 502; 1974).

Competition to lasers as a heat source for target compression in inertial confinement experiments comes from charged-particle beams, which can now be generated with very high electrical efficiencies. Considerable energies have already been delivered to small targets. Typical parameters for some present-day laser and relativistic electron-beam target-compression experiments are compared in Table 1. Assuming that ablation of a given target is self regulating, with energy deposition governed by the penetrating power of hot coronal electrons, the absorbed power requirement should be comparable for both laser and particlebeam approaches to inertial confinement. A fundamental problem for the particle approach may thus prove to be the generation of sufficiently high power beams, and their subsequent application at high, uniform intensities to sub-millimetre targets. Winterberg has recently made the interesting suggestion that 1-10 MV heavy ions, having an energy distribution which is instantaneously mono-energetic but which varies with time, might provide a convenient means for axial (time) compression of the beam after passage through a neutralising drift tube (Nature, 251, 44; 1974). Although 300 keV proton beams of approximately 75 J energy have recently been produced with an efficiency of 40% (Bull. Am. phys. Soc., Series II, 19, 871; 1974; papers 2C 14 and 15) no experimental attempt at pulse compression of heavy ion beams has yet been reported. If suitable high-intensity ion-beam techniques could be developed and successfully demonstrated in a compression experiment, the relatively high efficiency with which power could be deposited in the target might provide strong competition to other inertial-confinement approaches.

esent laser tech-In summary niques seem to offer the most immediate prospect for generating very high density plasmas. Significant laser developments will however be required to permit high-efficiency heating of isolated fuel targets, and to face a potential challenge from charged particle beam techniques for practical fusion energy applications. The likely time scale and scientific challenge to both approaches closely parallels current controlled thermonuclear reactor magnetic confinement programmes.

#### Probing nuclear band structure

from P. E. Hodgson

Many nuclei have low-lying states that are readily interpreted as members of a rotational band. Their energies follow quite closely the values expected from the quantum-mechanical theory of a rigid rotator, and their spins follow typical rotational sequences like  $0^+, 2^+, 4^+ \dots$  or  $\frac{1}{2}^+, 3/2^+, 5/2^+ \dots$  depending on the spin of the lowest member of the band. Furthermore, the transition probabilities for the excitation and de-excitation of these bands are found to be in good accord with the same quantum-mechanical theory.

Many such bands have now been found, especially in the regions of the periodic table far from the closed shells where nuclei are frequently deformed. But though it may be easy to identify the lower members of a band it is

often difficult to identify the higher members as there may be several states of the appropriate spin with approximately the right excitation energy. The identification is frequently made more difficult by quantum-mechanical mixing of the states of the same spin belonging to different bands that perturbs the simple sequence of energies.

Some recent work by Anantaraman and colleagues at the University of Rochester (Phys. Rev. Lett. 33, 846; 1974) has shown that the (6Li, d) reaction can sometimes be used to assist the identification of members of a particular band. Previous work had already shown that this reaction is sensitive to the transferred orbital angular momentum, indicating its usefulness in nuclear spectroscopy. This means that when a nucleus is bombarded with 6Li ions many deuterons are emitted and the angular distributions of the deuterons of a particular energy leaving the residual nucleus in a particular state is characteristic of the orbital angular momentum L given in the reaction to the target nucleus. If the target has zero spin, the orbital angular momentum couples vectorially to the spin of the transferred particle giving the spin of the final state  $J=L\pm\frac{1}{2}$ . This ambiguity can usually be resolved by shell model considerations, or by other measurements, such as that of the polarisation of the emitted particle. If the spin of the target nucleus is not zero several orbital angular momenta can contribute and they can easily be separated if they have similar magnitudes and different shapes, as is often the case. As before this determines or sets limits to the spin of the final state.

The Rochester group studied the reaction  $^{29}\text{Mg}(^{9}\text{Li}, d)$  to states of  $^{29}\text{Si}$ . It was already known that the rotational model is able to describe some of the low-lying states of  $^{29}\text{Si}$  by assuming that they belong to oblate  $K=\frac{1}{2}^{+}$  and  $3/2^{+}$  rotational bands. The  $K=\frac{1}{2}^{+}$  band is based on the ground state and has members  $\frac{1}{2}^{+}$  (0.0 MeV),  $3/2^{+}$  (2.43

## Glow discharge optical spectroscopy

from John Walker

Transistors, integrated circuits, solid state lasers and many other electronic devices are made by introducing impurities into silicon, germanium and compound semiconductors like gallium arsenide. The impurities are usually diffused in at a high temperature or are ionimplanted (fired into the material at a high speed after being accelerated by an electric field). In either case the impurity atoms are not distributed uniformly throughout the semiconductor crystal—their con-centration varies with depth. The precise variation (the 'profile') needs to be known, because it affects the production yield and the quality of the device. In general, profiles cannot be calculated accurately: they must be measured. Although various techniques are available, in one technologically important case. boron in silicon, they are either not applicable, too inaccurate, or complicated and expensive.

To resolve this problem a group of workers at the University of Illinois (Greene et al., Applied Physics Letters, 25, 435; 1974) have devised a modification of the wellknown technique of spectrographic analysis which they call "glow disoptical spectroscopy" charge (GDOS). The boron-doped silicon sample is bombarded by argon ions in an electrical discharge. This knocks atoms out of the sample, which are then excited in the discharge and emit light of particular wavelengths. Just as sodium street lamps give out an orange light characteristic of sodium atoms, so a boron discharge emits ultraviolet light at a particular wavelength. The more boron atoms there are in the silicon crystal the more intense the light emitted. Furthermore the crystal surface is gradually worn away by the boron ion bombardment, so that the change in boron concentration with depth can also be investigated.

When the method was applied to a diffused sample the measured boron profile was found to depart from the theoretical distribution by a factor of ten at some depths, confirming the inadequacy of calculations. A second silicon wafer, into which boron had been ion-implanted, had a maximum concentration at a depth of 430 nm, in agreement with calculations, but some boron had penetrated much further into the crystal than the simple theory predicted—an observation also made by other workers.

These results indicate the effectiveness of GDOS in detecting and profiling boron impurity in silicon. The method can be used on other impurities, and on compounds. For example, it has been applied to tin in gallium arsenide. Insulators can also be tested, and impurities need not be electrically active. The equipment is relatively simple, and available in most laboratories. Glow discharge optical spectroscopy obviously has a bright future, particularly in the electronics industry.

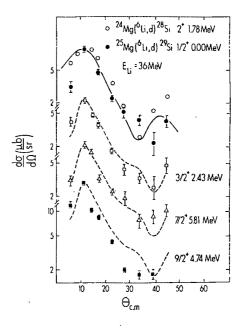

Fig. 1 Differential cross sections for the <sup>24</sup>Mg(<sup>8</sup>Li, d)<sup>28</sup>Si reaction to the 2<sup>4</sup> state at 1.78 MeV and for the <sup>23</sup>Mg(<sup>8</sup>Li, d) reaction to the states of <sup>29</sup>Si forming the K=½<sup>+</sup> band. The full curve is a distorted wave calculation of the cross section of the first reaction, and the dashed line is a smooth curve drawn through the data for the second reaction to the ½<sup>+</sup> state. All these reactions thus have the angular distribution characteristic of L=2 transfer.

MeV),  $5/2^+$  (2.03 MeV) and  $9/2^+$  (4.74 MeV), and the K=3/2 band has members  $3/2^+$  (1.27 MeV),  $5/2^+$  (3.07 MeV).  $7/2^+$  (4.08 MeV),  $9/2^+$  (5.65 MeV) and  $11/2^+$  (7.14 MeV). The energies are not in regular sequences due to the considerable band mixing. There is a missing  $7/2^+$  member of the K= $\frac{1}{2}^+$  band and there are several possible candidates, but it was not known which is the member of the band and which belong to quite different configurations.

Studies of the angular distributions of the deuterons from the reactions that go to each state in the  $K=\frac{1}{7}$  band showed that they are all the same and have the characteristic shape of an L=2 transfer. This shape is known from studies of the 24Mg(6Li, d)28Si reaction to the 2+ state at 1.78 MeV, which can only go by L=2 transfer. The 25Mg(6Li, d) reaction to the 1+ ground state of 29Si can also go only by L=2 transfer, because the spin of <sup>25</sup>Mg is 5/2+, but all the other reactions to higher members of the  $K=\frac{1}{2}$  ground state band can in principle go by several different values of L. Thus for example the reaction to the 3/2+ state can go by L=2 or 4, as these are possible solutions of the vector equation 5/2+L= 3/2+ (the odd values of L are excluded by the requirement of parity conservation). Nevertheless as shown in Fig. 1 only the lowest L=2 transfer is found in this and in all the other transitions

to this band. Among the possible candidates for the  $7/2^+$  member of the band is the state at 5.81 MeV that shows just the same angular distribution; this is suggestive but not conclusive as not all the  $7/2^+$  states were resolved in the experiment, so other candidates are possible.

In sharp contrast to this uniform L=2 behaviour the angular distributions of the <sup>23</sup>Mg(<sup>6</sup>Li, d) reaction to states of the K=3/2<sup>+</sup> band, shown in Fig. 2, have the irregular behaviour characteristic of a mixture of the allowed L-values. The curves in the figure correspond to various mixtures of .L-values, as determined by the <sup>24</sup>Mg(<sup>6</sup>Li, d) reaction. This sharp difference in the behaviour of the reactions to these two bands is all the more remarkable in view of the strong mixing between the two bands.

The mixing of the L-values for the transitions to the  $K=3/2^+$  band shows that the predominance of L=2 in the transitions to the  $K=\frac{1}{2}$  band is not due to kinematics but must therefore be due to differences in nuclear structure. At present there is no explanation for this behaviour, and it shows the need for more detailed nuclear structure studies.

It is, however, not necessary to understand the reason for the different behaviour of the transitions to the two bands in order to use it empirically as a way of identifying the different bands. It is likely that many other bands will be found to have characteristic signatures, and that these reactions will provide a useful way of studying the structure of rotational nuclei. It will also stimulate nuclear reaction calculations to try to understand the difference in the structures of the bands that give rise to this effect.

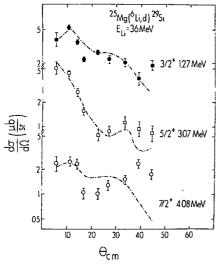

Fig. 2 Differential cross sections for the <sup>25</sup>Mg(<sup>6</sup>Li, d) reaction to the states of <sup>29</sup>Si forming the K=3/2+ band. The curves for the 3/2+ and 7/2+ states are mixtures of L=2 and L=4 distributions and that for the 5/2+ state is a mixture of L=0 and L=2 distributions.

# Structure of molecules in solution

from J. Feeney

To reach an understanding of biological recognition processes such as those involved in enzyme-substrate hormone-receptor interactions will require a detailed knowledge of the three-dimensional structures and the potential flexibility of the component molecules. Inspired by this challenge, Dr R. E. Richards, FRS and Professor R. J. P. Williams, FRS organised a meeting on November 21 at The Royal Society to discuss the present status of the various experimental methods for determining structures and conformations in solution. Although it is clear that none of the available methods offer the high precision of structural information provided by X-ray diffraction, some of these methods allow one to answer the important question of whether the unique conformation present in the crystal is the only one present in solution. Several speakers explored the applications of nuclear magnetic resonance (NMR) spectroscopy to these problems and this method emerged from the discussion as the dominant technique for providing conformational, dynamic and ionisation information for molecules in solution.

R. J. P. Williams (University of Oxford) illustrated how the conformation of ligands such as nucleic acids and peptides can be obtained from the chemical shift and relaxation time perturbations caused by the binding of a paramagnetic lanthanide ion to the molecule. When the interactions can be shown to be dipolar in origin then the chemical shift perturbations depend on  $r^{-3}$  where r is the internuclear distance between the lanthanide ion and the perturbed magnetic nucleus (proton, carbon, phosphorus) and an orientational term  $(3\cos^2\Theta - 1)$  where  $\Theta$  is the angle between this internuclear vector and the principal symmetry axis of the complex. Relaxation changes when using a lanthanide ion such as Gd3+ are isotropic and depend on  $r^{-6}$ 

A computer-simulated NMR spectrum is then generated for the fixed conformation which best fits the observed data. Only if there is an excellent fit for both the chemical shift and relaxation time perturbations can one assume that there is predominantly a single conformation in solution. • It became clear from the discussion that it is possible by careful experimentation to demonstrate the validity of the approach for rigid molecules. But for potentially flexible molecules such as peptides, the 'conformation' as formed by this technique is not simply related to the distribution of conformations but probably reflects the most populated conformation.

J. Feeney (National Institute for Medical Research, London) described an alternative NMR method of obtaining conformational information involving the well-established procedure of relating measured three-bond H-H spin-coupling constants ( $^{3}J_{HH}$ ) to the dihedral angle \varphi about the central bond. When the form of the  ${}^3J_{\rm HH}/\varphi$ relationship (the so called Karplus equation) is known for a particular system it can be used to define dihedral angles in molecules of fixed conformation. For flexible molecules it is possible to estimate the fractional populations from the averaged coupling constants and this allows one to check potential energy calculations. The method has been extended to three bond coupling constants involving other nuclei (1H-13C, 1H-31P and 1H-14N). Various applications to cholinergic neurotransmitters and hormonal peptides were considered. It is clear that for small molecules which are potentially flexible a combination of the spin-coupling constant approach with the lanthanide induced shift measurements is required to obtain the maximum amount of conformation information.

For larger molecules such as the enzyme lysozyme where one expects a unique conformation in solution, the full potential of the lanthanide induced shift technique can be realised. C. M. Dobson and I. D. Campbell (University of Oxford) described how the spectral perturbations caused by binding lanthanide ions to hen egg white lysozyme in solution could be interpreted in terms of the crystal structure of lysozyme, thus indicating that the solution and solid state conformation are very similar. By the elegant use of NMR difference spectroscopy most of the proton resonances in close proximity to the lanthanide ion binding site can be assigned with confidence. Dr Cambell showed how many other proton assignments in lysozyme can be made independently of the X-ray diffraction crystal structure. By using high magnetic fields and computational methods of resolution enhancement many of the proton resonances could be resolved and assigned from a consideration of their multiplet structures, and results from double resonance methods, pH titrations, chemical modifications, paramagnetic probes and inhibitor binding. On the basis of these experiments it is clear that this method can be extended to proteins where the X-ray structure is not yet available. As pointed out by Campbell and Dobson, the assigned resonances may be used to monitor interactions between catalytically important groups, to determine their ionisation states and to deduce the mobilities of the side chains of certain residues.

T. G. Spiro (Princeton University) showed how resonance Raman spectroscopy of haem proteins can be used to detect deviations from planarity of the porphoryin ring and other structural consequences of changing the spin and oxidation states in the haem groups. The vibrational modes containing this information exhibit greatly enhanced Raman scattering when an electronic transition to which they are coupled is irradiated with laser excitation.

X-ray and neutron scattering techniques were considered by J. E. Enderby (University of Leicester) and J. W. White (University of Oxford). Because the neutron diffraction scattering length for the proton is opposite in sign to that for deuterium, by using mixtures of H<sub>2</sub>O/D<sub>2</sub>O it is possible to achieve high contrast between the scattering from the solvent and from the solute molecules. For inelastic scatter-

ing there is a large difference in cross section between protons and deuterons which allows observation of the dynamic behaviour of individual components in the various phases of amphiphile/water systems. Low angle neutron diffraction studies on hydrated collagen and tobacco mosaic virus solutions lead to information about the radii of gyration of the molecules in solution.

From measurements of the quasielastic spectrum of laser light scattered from macromolecules in solution, G. B. Benedek (Massachusetts Institute of Technology) showed how accurate diffusion coefficients can be obtained. When considered together with sedimentation data these values provide molecular weights. The size and shape of the macromolecules can also be deduced. Interesting differences in the apparent volumes of lysozyme when denatured by different methods (guanidine and heat) were observed but no evidence for intermediate states in the unfolding process could be detected. The technique is capable of monitoring aggregation of macromolecules and this was well illustrated by a study of the manner in which the aggregation of glutamate dehydrogenase controls the amount of enzyme in its active form.

Most of the techniques considered have still to reach their full potential in their application to structure determination in solution and rapid progress can be anticipated over the next few years.

# Huntingtons's chorea and GABA

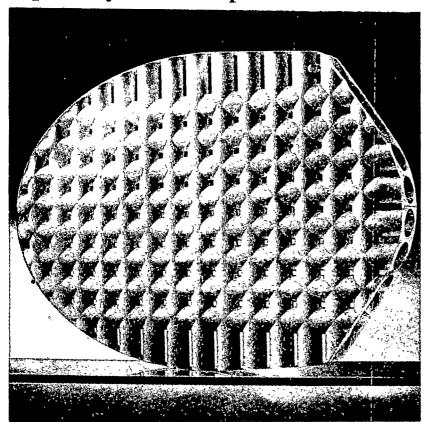

from T. J. Crow

THE apparent diversity of chemical neurotransmitter substances (there are now at least seven with good credentials) in the brain has encouraged the search for specific neurohumoural disunderlying neurological turbances diseases of obscure actiology. Ehringer and Hornykiewicz' discovery (Klin. Wschr., 38, 1236-1239; 1960) of a deficiency of dopamine in the basal ganglia in Parkinson's disease led to the introduction of L-DOPA in treatment. Now it is suggested that another progressive disease of the 'extrapyramidal' motor system, Huntington's chorea, is associated with a specific deficiency of GABA (γ-amino-butyric acid) in the same brain regions.

GABA, known for 20 years to be present in brain, has a regional distribution which follows that of its synthetic enzyme glutamine acid decarboxylase (GAD), and both are present in synaptosomal fragments. GABA is in high concentration within the striatum, globus pallidus and substantia nigra, structures within the extrapyramidal motor system, and also within the cerebellar cortex and nuclei (Fahn and Coté, J. Neurochem., 15, 209-213; 1968). The presence of a high-affinity uptake system and the demonstration of release following neural stimulation provide further evidence that this substance has a neurotransmitter role, and microionophoretic data suggest that at several sites GABA is an inhibitory transmitter. The recent development of an immunohistochemical technique by Saito et al. (Proc. natn. Acad. Sci. U.S.A., 71, 269-273; 1974) for GAD may greatly facilitate the task of localising particular gabaminergic systems.

Huntington's chorea is transmitted as an autosomal dominant condition which may affect between 4 and 7 per 100,000 of the population. The disease owes its persistence, and its peculiarly sinister character, to the fact that the average age of onset (44 years, according to Wendt) is beyond the normal period of fertility. Thus by the time symptoms appear the patient may have

## Optical systems for space

• photograph by Tinsley

The mirror illustrated (made by Tinsley in Berkeley, California) is designed to be part of a rocket-launched optical system. The grid pattern is formed by a series of holes drilled through the core to minimise weight. Because of the high stresses experienced in a large object during a launch, the accuracy of machining is critical and is evident in the regularity of intersection of the holes.

children who in turn face the prospect that they may develop the condition. The disease has both neurological and psychiatric aspects in that the development of jerky, uncontrolled, choreiform movements precedes a steady progression into dementia. Panse (Die Erbchorea; Leipzig, 1942) has demonstrated that a substantial minority of cases pass through a paranoid psychotic phase with schizophrenia-like features early in the illness. An understanding of the mechanism of these changes might have implications beyond the field of motor control.

Perry et al. first reported a deficiency of GABA in the brains of patients dying from Huntington's chorea in 1973 (New England J. Med., 288, 337-342). Later that year Bird and his colleagues (Lancet, i, 1090-1092) and McGeer et al. (Neurology, 23, 912-917) reported a reduction in the levels of GAD, which is presumed to be a marker for gabaminergic neurones. Now Bird and Iversen (Brain, 97, 457-472; 1974) have presented a detailed study of the brains of 38 patients dying with the disease and 38 controls of similar age dying from other causes. In this study the time between death, postmortem and subsequent freezing of the tissue was kept to a minimum. Glutamic acid decarboxylase activity in the choreic patients was reduced by 75% in the basal ganglia, but not in the frontal cortex. GABA concentrations were reduced by 50%, and choline acetyltransferase concentrations by 55%, although these latter were within the normal range in a substantial proportion of the brains. Tyrosine hydroxylase activities and dopamine concentrations did not distinguish the two groups although a subgroup with rigidity (a possible variant of the disease) had significantly higher dopamine concentrations. Bird and Iversen argue that the most consistent lesion in Huntington's chorea may be a loss of GABAcontaining neurones, with, in some cases, a loss of cholinergic neurones. In a study on part of the same postmortem material Hiley and Bird (Brain Res., 80, 355-358) have shown that there is sometimes a loss also of the cholinergic muscarinic receptor. That this post-synaptic change may precede the loss of the pre-synaptic cholinergic neurone is suggested by the observation that normal choline acetylase levels are sometimes present with reduced concentrations of the muscarinic receptor.

These findings provoke a number of questions concerning possible neuro-chemical-clinical correlations. For example although there is electrophysiological evidence for a role for GABA-containing neurones in the cerebral cortex, there is no evidence in the recent study that these neurones are affected by the disease process. Therefore on

the evidence thus far available the dementia of the disease must be explained on the basis of subcortical changes, or some non-gabaminergic cortical cellular dysfunction. Second, there has been considerable interest in GABA in the cerebellum (a paper by Wilkin and co-workers in a recent issue of Nature (252, 397; 1974) presents convincing radioautographic evidence that the inhibitory Golgi cell terminals on the granule cell dendrites are one cerebellar site at which a high affinity GABA-uptake system is present). Huntington's chorea is not generally considered to be a cerebellar disease, but there is sometimes histopathological evidence of cell loss in this structure. Is it possible that such cell loss, when it occurs, is also of GABA-containing cells? Finally one might speculate concerning the paranoid psychotic changes which are occasionally seen early in the disease. Recently there has been interest in the hypothesis that excess dopaminergic activity underlies the paranoid form of schizophrenia. As Bird and Iversen point out the histopathological atrophy in Huntington's Chorea may lead to a relative increase in the density of innervation by surviving nigro-striatal dopaminergic terminals. Therefore a neurohumoural imbalance at this level provides a possible basis for the development of a paranoid psychosis which in turn may disappear when continued cell loss leads to the supervention of dementia.

# Superconducting flux structure probed with positive muons

from P. G. Harper

ONE of the characters making a brief appearance in the drama of parity nonconservation (1956) was the positive muon  $(\mu^+)$ . This fundamental particle is analogous to the positron, but differs in mass (about 130 times larger), and attendant decay neutrinos. It is emitted from the decaying positive pion  $(\pi^+)$ in a spin-polarised state, that is to say, with its magnetic moment tending to lie along its direction of propagation. The  $\mu^+$  is relatively long-lived with a half-life of 2.2  $\mu$ s, and decays by positron (e+) emission. The angular distribution of the latter is anisotropic with respect to the direction of  $\mu^+$  polarisa-

These basic properties of the  $\mu t$  enable it to be used as a probe to examine magnetic materials such as Fe and Ni. and very recently (*Phys. Rev. Lett.*, 33, 969; 1974), the type II superconductive flux structure. The principle is that if a  $\mu^+$  rests in a local magnetic field, its magnetic moment (or spin axis) will rotate (precess) about

the field direction at a rate proportional to the field. Because of the emission anisotropy, the instantaneous axial tilt at the moment of decay imparts a corresponding perturbation to the e<sup>+</sup> angular distribution. The positron emission, detected by coincidence counters in some fixed direction, thus follows the  $\mu^+$  precession so that the overall time decay is modulated at the precession period. For a field of 500 G, this would be about 0.01  $\mu$ s. Since the gyromagnetic ratio for  $\mu^+$  is known with considerable accuracy, the local magnetic field can be readily deduced.

The method thus resembles the socalled 'time-dependent perturbed angular correlation' technique employed with radioactive species. The advantage of a  $\mu^+$  beam is that it does no damage and leaves no residual contamination. Of course, when the method is employed to probe a non-uniform field distribution, the e<sup>+</sup> count records a space-averaged precession so that the frequency spectrum of the modulation requires careful interpretation.

The superconductive flux structure mentioned above is perhaps the most bizarre magnetic ordering found in any low temperature solid state phase. Present physical understanding of this phenomenon is fairly complete, and is hased on developments of the remarkable 1950 theory of Ginsberg and Landau. Whereas for a thick specimen of lead, say, in its superconductive state, a weak applied magnetic field may be completely internally extinguished within 0.1  $\mu$ m of a parallel surface, in a type II material such as a lead-indium alloy, a similiar field can penetrate right across the interior. It succeeds however only by condensing regularly into quantised filamentary flux lines (or vortices) which run parallel to the external field; they form a two-dimensional hexagonal structure with a flux-line density equal to the ratio of total flux to the universal flux unit, hc/e. At the centre of each flux line, the material is actually in its normal state, so that the induction achieves its maximum (that is, external) value. Away from the centre the induction declines, while at the same time the degree of superconductivity increases. Near the mid-point of neighbouring centres the induction forms a saddle-point. A strong hope for the  $\mu^+$ technique is that it might reveal and measure the saddle-point local field.

Of course, other methods have been used to probe the flux distribution, notably NMR, neutron diffraction, molecular beams and decoration microscopy. The present experiment therefore is largely to test a fairly novel technique, though additionally, it reveals some features of  $\mu^+$  behaviour.

The alloy  $Pb_{0.90}I_{0.01}$ , and Nb were.

examined for comparison in the normal state, with the field applied, and with same field in the superconductive state. The latter was prepared by (1) cooling in the steady field to the mixed state, and (2) cooling in zero field, and then switching on. The results for the alloy were encouraging. For procedure (1), the main Fourier component of the modulated count (corresponding to the frequency of the applied field) was observed to broaden upon cooling to 5.5 K: upon further cooling to 3 K, a bifurcation was resolved, and a satellite peak identified as arising from the saddle-point mentioned above. Procedure (2) however showed no such splitting, indicating that the structure was smeared out by the preparation. Less exciting results were found for the Nb. No splitting was observed with either (1) or (2), but the main (external field) line appeared with much larger amplitude.

The authors conclude their report with a discussion concerning the possible diffusion of the  $\mu^+$ . Far from being simply trapped at a favourable location the tunnelling rate between Nb sites is estimated as being at least  $10^{12}$  s<sup>-1</sup>. If the observed sharp line in Nb is attributed to motional narrowing (as occurs in NMR for example) a large diffusion constant of the order  $10^{-2}$  cm<sup>2</sup> s<sup>-1</sup> is needed. At present, actual diffusion mechanisms remain speculative and the authors plan further work to resolve them.

#### **Comet chemistry**

from M. K. Wallis

"THE Study of Comets", The International Astronomical Union Colloquium No. 25, held from October 28 to November 1 at NASA's Goddard Space Flight Center in Maryland, was timed to take stock of new data from comet Kohoutek and also to precede critical decisions on a possible cometary space probe.

Most of the active comet researchers from the United States and Western Europe put in an appearance, but unfortunately, in spite of sponsorship from the IAU and the International Committee on Space Research, nobody from the strong Soviet and Czech groups attended.

Much interest was attracted by the reports of the new molecular emissions, revealed in the ultraviolet and radio spectra. The 1,304 and 1,657 Å multiplets have given data on atomic oxygen and carbon, reported P. D. Feldman of Johns Hopkins University. And the radio observations, reviewed by L. E. Snyder (University of Virginia) have revealed CH, OH, HCN and CH<sub>3</sub>CN in comet Kohoutek and H<sub>2</sub>O in comet

Bradfield. Quantitative interpretation is thwarted however, as all except the HCN emission is pumped. The repeated failure to detect the predicted formal-dehyde (H<sub>2</sub>CO) emission is also put down to pumping.

Surprisingly, there is also a new identification in the optical—of H<sub>2</sub>O<sup>+</sup>—a joint effort with P. Benvenuti (Asiago Observatory, Italy) and P. Wehninger (University of Tel-Aviv) as G. Herbig of Lick Observatory related. There are numerous lines from this ion, from the head and from far in the tail. They can be found on old spectra and the ion is probably very common as cometary plasma tails frequently show up on red-sensitive photographic plates, which should exclude the normal CO<sup>+</sup> emissions.

Arpigny of Liège (Institut C. d'Astrophysique) reported progress in the interpretation of molecular spectra. in particular in modelling collisional changes to the relative populations and line strengths of the purely resonant fluorescent description. Applying this potentially powerful method to the CH bands has given a reasonable total density in comet Bennett, with temperature of the colliding agent in the range 4-800°K. Analyses of the extensive H-coma were reported by H. U. Keller of LASP (University of Colorado), who has made this topic his own. All observations give outflow velocity in the range 7-10 km, which may correspond to the as yet unknown surplus energy of OH photodissociation. But the distant Lyman-a profiles of comet Bennett, observed from OGO-5, require for their explanation an atomic H component of higher velocity, around 20 km s<sup>-1</sup>, as would be expected from the photodissociation of H<sub>2</sub>O.

Including the new identifications. A. H. Delsemme (University of Toledo) advocated the simple two-stage picture of the cometary coma: H<sub>2</sub>O and certain unknown parent molecules expand radially outwards and dissociate into daughter radicals and atoms, which are subsequently destroyed by ionisation. He gave length scales for the hypothetical parents and observed daughters. But a paper by C. K. Kumar and R. J. Southall of Howard University reported widely different scales in various comets for the supposed parents of CN and C. And a chemist, R. Oppenheimer of Harvard, emphasised in a spirited contribution that numerous ion-molecule and dissociation-recombination processes can proceed rapidly inside 10.000 km in the coma. Various complex reaction chains could occur, resulting in CH2 CN. C2 and, in principle, even H<sub>2</sub>O! The fundamental constituents of comets are still very much in doubt.

H. U. Schmidt of Munich (Max-Planck Institut für Physik und

Astrophysik) reviewed progress in the fluid description of plasma motion through the coma. He considered that magnetic stress from the distorted field of the solar wind would reduce the distance of the contact discontinuity dividing off the purely cometary plasma, but explanations of how structures were produced from this plasma and gave rise to the observed tail were still lacking. M. K. Wallis (University of Oxford) argued, however, that because of cooling and recombination processes, the 'contact discontinuity' would occur inside the 10,000 km collisional region and therefore have little significance.

Sequences of pictures of ion tails of various comets had been made into a film by K. Jockers (Sacramento Peak Observatory). This illustrated particularly that subsidiary systems of rays sometimes arise from condensations in the tail and that nearby condensations and wave features move at similar speeds, so would appear to be convected features in a general flow. Progress was being made in the theory of dust tails, reported Z. Sekanina (Smithsonian Astrophysical Observatory). The fact that the 'silicate signature' in the infrared emission is not present in the anti-tail proves the particles differ in size.

There was as ever speculation about processes of comet formation: A. Mendis (University of California, San Diego) suggested that they could be accreted on the time scale of 10<sup>3</sup> years in present-day meteor streams; F. L. Whipple (Smithsonian Astrophysical Observatory) wished to use the compression of a solar gale from the young sun, while B. Donn (NASA: Goddard Space Flight Center) reckoned comets might be formed in a dense cloud within the cluster from which the sun emerged.

As to the long discussed mission to a comet, a space probe to comet Encke in 1980 now has a reasonable chance, reported I. Rasool (NASA). With a 'slow fly-by at 8 km s<sup>-1</sup>, the nucleus could be photographed and the neutral coma and plasma coma and tail could be investigated.

It is aimed to publish both impromptu and scheduled talks, by courtesy of NASA. in what will surely be voluminous conference proceedings.

#### Correction

The source of the illustrations from the ceiling of the British Museum (Natural History) (Nature, 252, 193; 1974) was not acknowledged: they were reproduced from the Botany Leaflet No. 1 published by the British Museum (Natural History).

# Pupils of a talking parrot

Richard Gregory\* & Prue Hopkins†

Chance observations on a talking parrot have led to an investigation which reveals a striking temporal relationship between pupillary constriction and learned utterances.

A FEMALE talking parrot of the species known in this country as Yellow Fronted Amazon, Panama variety (Amazona ochrocephala panamensis), about nine years old and owned for the last five by one of us, exhibits marked constriction of the pupils of the eyes when she talks. She has a repertoire of about twenty words, calls, whistles and various recognisable sounds which are frequently uttered—accompanied by sudden and large pupil contraction. Once noticed, this is unmistakable, at least in Seraphita.

Although normally the pupils remain of almost constant size, even over large changes of illumination, during utterances

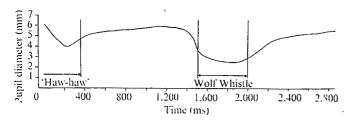

Fig. 1 Sample of analysed record (smoothed) showing shrinking pupil immediately preceding and during parrot's utterances.

they shrink rapidly to about half their resting diameter. This was such a clear and repeatable phenomenon that we decided to record it, and especially to discover time relations between the pupil shrinking and speech. During these investigations we found that the pupils would sometimes respond similarly while the parrot was listening to familiar words or sounds. Further, occasionally there would be a small shrinking of the pupils immediately prior to her speaking; as though, we thought, following some kind of internal 'rehearsal' for speech production. These further effects are smaller and more variable than the original effect observed, but after many hours of observation we are confident of them also, and have film records of their occurrence. It is known that the iris muscles are striated1, which helps to explain the lability. There is no consensual reflex: varying illumination to one eye does not produce pupillary changes in the other eye. With the speech changes, however, both pupils move together.

The effects were recorded on several occasions, over a period of two years, on video tape with sound track. Technically satisfactory sections of the video tape records were transferred to 16-mm film, with magnetic sound strip. Transfer to film was undertaken because freezing the video tape on the video tape recorder (1-inch Ampex) gave an unsteady picture and \*MRC Brain and Perception Laboratory, Department of Anatomy, The Medical School, University, Walk, Bristol BS8 1TD. †(Seraphita's home) White Gates, 4 Church Lane, Abington, Cambridgeshire.

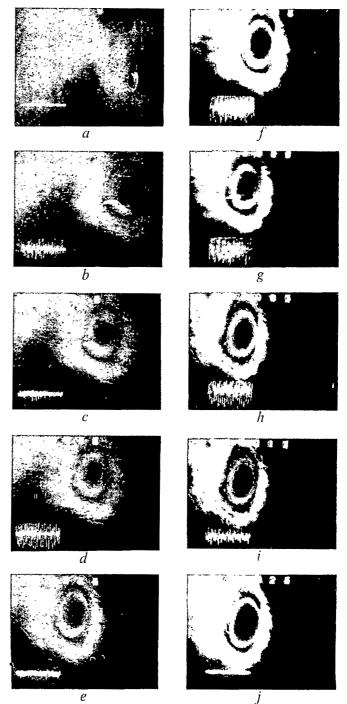

Fig. 2 Sequence from cine film of video tape, with oscilloscope record of parrot's 'wa-ha-he-e-y', electronically mixed in real time a, Time 0; b, 240 ms; c, 400 ms; d, 480 ms; e, 720 ms; f, 1,000 ms; g, 1,240 ms; h, 1,520 ms; i, 1,760 ms; j, 2,080 ms.

Speech started at 160 ms.

caused tape damage. The transfer allowed us to superimpose an oscilloscope record of the sound track, for measuring time relations between speech and pupil changes. The film camera was synchronised at 25 frames s<sup>-1</sup>, to the 25 s<sup>-1</sup> frame scan of the video system allowing time intervals to be estimated in 40 ms steps. The stop-motion projector has no sound head, so each section of speech was first classified, on an editor with a magnetic sound head (whose viewing screen was however too small for analysis) and a tape cassette of the sound track was also made for later checks. The moving inner edge of the iris—the pupil—and the unchanging outer edge of the iris of a single eye, were traced frame by frame from the magnified image given by the stop-motion projector, for sequences selected for maximum definition of the eye and when the bird's head was still. Diameters of the outer edge of the iris and of the pupil were measured both horizontally and vertically. Pupil measures were only accepted when the measures of the outer edge remained essentially constant, when measured changes of pupil size could not be due to changes in distance of the eye from the television camera.

Pupil contraction was found to start 4–5 frames before the bird's speech, which was clearly shown by the superimposed oscilloscope record of the sound track. The pupil contraction is therefore anticipatory to its speech by about 200 ms. Often contraction is nearly completed at the start of the utterance. The pupil diameter, both horizontal and vertical, shrinks by up to half the resting diameter. Contraction seems to occur for all utterances except for (innate?) very short squawks, present on sound tracks only for single frames of the film and so for less than 40 ms duration. Contractions are shown in the graph (Fig. 1) and in the sequence of cine frames from video tape (Fig. 2).

Pupil changes associated with our utterances were more variable, and by no means always present. They seemed to occur only when the parrot was 'attending'—gazing at us with a single steady eye—and only when we uttered one of her favoured words or sounds. Some of these are her name, "Seraphita"; "Hello"; "Goodbye"; "Good boy"; "Arrio" (a Spanish exclamation);

"Pretty boy"; "Prue"; and other names of her intimate acquaintance. She also has a very human laugh and an accurate telephonebell sound. The pupils contract most dramatically for what can only be described as a 'wolf whistle'. All these are uttered spontaneously, and they may be evoked by saying them to her. Most recently, we find that she can develop a new call within seconds of hearing a new sound. She produced an accurate copy of the distinctive whir of a motor-driven Nikon camera, immediately after its first brief run, when we were trying to capture her pupil closure with high resolution directly on film. This 'Nikon whir' call was spontaneously repeated several times.

A younger male blue-fronted Amazon (Amazona aestiva) was introduced into a neighbouring cage a year ago. This parrot does not talk. His pupils are found to remain of constant size—except occasionally when he picks up an unfamiliar object when a small contraction may take place. This has also occasionally been observed for Seraphita. So pupil contraction seems to be mainly though not quite exclusively associated with utterance, attending to certain familiar utterances and sounds and also sometimes, we are inclined to believe, to internal 'rehearsal'.

We have so far no theory to account for these phenomena; neither do we know how general they may be among talking birds. Could they be signals to command other birds' attention? The contraction of the jet black pupils surrounded by their brilliant gold irises is distinct enough for this. Are they associated with difficult tasks, including handling unfamiliar objects, when depth of field may be increased and perhaps also the lens accommodated for near precise vision? Or is this phenomenon no more than (in two senses?) a case of neural cross talk?

We conclude that talking parrots can be and have apt pupils but we cannot guess what they are apt to do.

We thank Philip Clark, Tony Makepeace, Anthony Downing and Freja Gregory for technical assistance.

# Audiofrequency vibrations and gravity-wave detectors

Edwin R. Fitzgerald

The Johns Hopkins University, Baltimore, Maryland 21218

Non-elastic audiofrequency vibrational modes in aluminium and other metals are suggested as a possible reason for the differences reported by various observers using large aluminium alloy bars (or disks) as gravity-wave detectors. Loading of suspended gravity-wave detector bars resulting from the gravitational attraction of the Earth is also sufficient to produce the small stresses required for the self-generation of audiofrequency sounds (acoustic emission) in materials. Both the non-elastic mode response and acoustic emission frequencies depend critically on the exact microstructure and/or residual stress state of a bar.

GRAVITY-wave detectors dependent on the excitation of elastic-wave vibrational modes in a solid have been cited variously as confirming<sup>1,2</sup> or not confirming<sup>3-6</sup> the existence of gravity waves. Most of these detectors consist of long bars of an aluminium alloy (exact alloy often unspecified) with

lengths chosen to give the first or fundamental longitudinal elastic mode of vibration in the audiofrequency range. The longitudinal modes of elastic vibrations in a free-free bar or rod have frequencies,

$$v_n(elastic) = nc_1/2l = (n/2l)(E/\rho)^{1/2}...$$
 (1)

where  $n = 1, 2, 3 \dots$ , l is the length of the rod,  $c_1$  is the longitudinal sound velocity in the rod, E is the longitudinal (Young's) modulus of the rod, and  $\rho$  is the density of the rod material. Longitudinal sound velocities in aluminium alloys range from about 4.5 to  $6.4 \times 10^5$  cm s<sup>-1</sup> so that rod lengths of 153 and 366 cm have been used for detectors with first-mode frequencies (n = 1) of 1,661 and 710 Hz, for example 1.2.5.

There are also non-elastic audiofrequency vibrational modes which depend critically on the exact microstructure or "texture" of a given sample, but are independent of elastic-wave velocities and macroscopic sample dimensions<sup>10,11</sup>. That is, non-elastic mode frequencies,  $v_{kq}$ , corresponding to an ordered arrangement of atomic masses,  $m_k$ , with spacings,  $d_k$ , extending over a

distance,  $S = Nd_k$ , in the material are given to a good approximation by

$$v_{kq}$$
 (non-elastic)  $\simeq (h/8m_kS^2)q^2$  (2)

where h is Planck's constant, and  $q = 1, 2, 3 \dots (N-1)$ . For these non-elastic modes to be observed in small-amplitude vibration experiments it is also necessary that some residual or applied steady stresses be present in the material to activate the modes. Characteristic lengths, S, are determined by the mosaic patterns in single crystals and the grain or subgrain diameters in polycrystalline materials. Such lengths are most often in the micrometre range<sup>12</sup>.

#### Vibrations in aluminium

For aluminium a value of  $S = 1.07 \times 10^{-4}$  cm gives a first-mode frequency of 1,660 Hz from equation (2);  $S = 2.14 \times 10^{-4}$  cm corresponds to a first-mode frequency of 415 Hz and a second-mode frequency of 1,660 Hz. That result is particularly interesting since Hiedenreich13 has used electron-microscope transmission to show that polycrystalline aluminium, heavily worked at room temperature, consists of slightly misoriented domains about 2×10<sup>-4</sup> cm across. Beck and Hiu14 confirmed these results, and Kellar, Hirsch and Thorp<sup>16</sup> used an X-ray microbeam method to show that pure aluminium worked at room temperature first had domains about 3.6×10<sup>-1</sup> cm wide which decreased to 2.2×10<sup>-1</sup> cm after prolonged resting at room temperature. The low order non-elastic mode frequencies given by equation (2) are very sensitive to the exact value of S; values of S, in turn, vary according to the thermal and stress history (quenching, cold-working, annealing, and so on) and states of a particular piece of a given material.

From equations (1) and (2) we see that identical mode frequencies for the two types of wave correspond to vastly different wavelengths. An elastic first-mode frequency of 1,660 Hz in aluminium corresponds to a wavelength of about 300 cm and the first non-elastic mode at the same frequency has a wavelength of  $4.28 \times 10^{-4}$  cm. Thus the usual piezoelectric crystal vibration detectors respond to the acceleration of some portion of a sample surface with dimensions much less than a wavelength (elastic mode) or much greater than a wavelength (non-elastic mode) at low audiofrequencies. In addition elastic mode frequencies for a bar of fixed length, I, increase as 1,2,3,4... whereas non-elastic mode frequencies for a given microstructural length, S, increase as 1,4,9,16...; a particular bar has only one macroscopic length, but may have a microstructure with several predominant characteristic lengths or a distribution of lengths about some mean value.

Experimental evidence of non-elastic audiofrequency modes (at room temperatures) for dynamic shear compliance measurements on small metal disks was first reported16 in 1957. Some of the differences in mechanical vibrational spectra found in samples formed from the same 0.25-inch diameter extruded bar of 2S aluminium are shown in Fig. 1 where the variation of complex shear compliance,  $J^* = J' - iJ''$ , with applied vibration frequency from 100 to 2,000 Hz is adduced for three samples. All sample disks were cut from the same bar and were of virtually identical dimensions. The first sample disks (a) have a large resonance near 1,040 Hz (actually a triplet with mode frequencies 1,040, 1,060, and 1,070 Hz). Smaller resonances appear at 1,355, 1,655, and 1,860 Hz. Other resonances, not shown in Fig. 1, were observed at 2,010, 2,370 and 2,520 Hz; 2,930, 3,260, and 3,480 Hz. The groups of triplet resonances are roughly in the ratios 16:25:36:49 so that first, second and third-order modes near 66, 265, and 595 Hz might be inferred; none of these, however, appears in the data for this first sample. The spectrum of the second set of disks (Fig. 1b) is quite different, with only small resonances at 250 and 970 Hz. The third sample (Fig. 1c) again displays a very small resonance at 265 Hz, a triplet at 970, 1,000 and 1,050 Hz, but no other dispersions below 2,000 Hz.

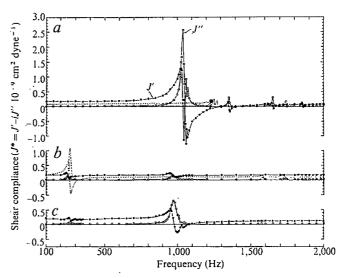

Fig. 1 Variation of complex shear compliance  $(J^* = J' - iJ'')$  with applied vibration frequency for three sets of small sample disks of 2S aluminium cut from the same extruded bar and of identical dimensions as described in the text. Dotted and dashed lines show measured values of J' and J'' respectively after No. 1 samples (a) were annealed at 1,100° F for two hours and after No. 2 samples (b) were compressed 3.0% in the direction of their axes. J' is the ratio of the in-phase component of resulting strain amplitude to the applied vibrating stress amplitude  $(a'/s_0)$  while J'' is the ratio of the 90° phase component of strain amplitude to the stress amplitude  $(a''/s_0)$  at each frequency. All measurements were made at room temperature  $(24 \pm 1^{\circ} \text{ C})$  using the method and measuring apparatus described in ref. 17, and extended from March 15 to May 14, 1962. Differences in measured compliances are attributed to variations in sample microstructures and stress states as discussed in text.

#### Cause of observed variations

These differences are, of course, attributed to differences in microstructure and/or residual stresses which vary from place to place in a material. Much larger differences in microstructures and stresses are to be expected between (and within) large bars from 5 to 10 feet long and weighing thousands of pounds such as those being used for gravity-wave detection.

Thermal and mechanical stress effects on the shear compliance spectra are demonstrated by the dotted and dashed lines (for J' and J'', respectively) in the groups of curves a and b in Fig. 1. These lines for the first sample (a) represent the results found after the sample was removed, annealed at 1,100° F for 2 h, found to have the original dimensions within  $\pm 0.0001$  inch, and then replaced in the measuring apparatus. Resonances above 2,000 Hz except the one at 2,920 Hz (moved to 2.930 Hz) also disappeared from the spectrum of this sample after annealing. By contrast the lines for the second sample (Fig. 1b) show the results found after this sample was removed and subjected to a 1,000-pound compressive stress on its parallel faces for one minute. The (mean) thickness decreased from 0.200 to 0.194 inch (3.0%) and the diameter increased as a result of this loading (major axis 0.2558, minor axis 0.2555). In addition to the large increase in the resonance at 260 Hz and the other changes shown in Fig. 1, the large resonance at 2,910 Hz 'moved' to 3,090 Hz after this load treatment.

The effects of annealing on the mechanical spectrum of the first set of 2S aluminium samples (Fig. 1a) are entirely similar to those previously reported for lead disks (99.9998 % purity).

#### 'Relevance to 'gravity-wave' observations

This discussion of the occurrence of non-elastic vibrational modes in materials is presented as a possible explanation for the differences found among various gravity-wave detectors; a particular aluminium alloy bar designed to be sensitive to vibrations at an elastic-mode frequency may, in fact, be responsive to an intrinsic, non-elastic microstructural mode

at the same (or nearly the same) frequency. Another bar of the same chemical composition and dimensions, even if cast or formed under supposedly identical conditions, may, because of slightly different thermal and/or stress histories or states, have a different microstructure and/or (mean) residual stress state which make it less responsive to the non-elastic vibrational mode frequency or frequencies found in the first bar.

A second possible explanation of the differences is that stress-induced acoustic emission (at particular, discrete frequencies) could be present and detected in some of the bars, but not in others. The same wave-mechanical theory of deformation<sup>10,11</sup> which describes the non-elastic vibrational modes previously cited also predicts the occurrence of smallamplitude audiofrequency vibrations during plastic deformation. An approximate expression for the net translational oscillating force on a lattice segment of length S in a material during steady loading is given by<sup>11</sup>

$$f_q(t) \simeq (B_1 h / Sd_k) q \exp(-i2\pi v_{kq} t)$$
 (3)

where h is Planck's constant,  $d_k$  is the regular spacing between atoms of mass  $m_k$ , extending over a distance  $S = Nd_k$ ,  $B_1$  is a velocity constant depending on the load magnitude (the macroscopic stress) and the oscillation frequency,  $v_{ky}$ , is given by equation (2), where q = 1,3,5... An estimate<sup>11</sup> of the mean force amplitude in equation (1) for q = 1 and  $B_1 = 10^3$  cm s<sup>-1</sup> is about  $2 \times 10^{-8}$  dyne cm<sup>-1</sup>. An oscillating force on the individual ordered segments of micrometre length within materials will tend to set into vibration (portions of) the entire sample; these sample vibrations will ordinariy be of very small amplitude unless a number of individual segment vibrations occur simultaneously throughout some appreciable volume of the sample. Contributions from even modes are absent from the net translational forces on segments (q =1,3,5,7..., equation (3)), but even modes do produce net oscillating moments on the lattice segments11 with amplitudes  $(B_1h/2d_k)q$  for q = 2,4,6...

The occurrence of audible sounds during severe plastic deformation is, of course, well known<sup>17,18</sup>. Of more interest to the present discussion of gravity-wave detectors, however, is the occurrence of much fainter sounds at very low stress (and strain) levels, continuing through yield as reported by Kaiser<sup>19</sup>. Sensitive piezoelectric crystal detectors similar to those used on the gravity-wave detector bars, and a very quiet loading system, were used by Kaiser to study audiofrequency sounds emanating from polycrystalline zinc, steel, aluminium, copper, lead and wood specimens loaded in tension.

An extensive investigation of acoustic emission has been carried on since 1954 by Schofield<sup>20-22</sup> over a range of stress levels, and on both single crystals and polycrystals of gold, zinc, aluminium, lead, cast tin, carbon steel and 24ST-4 aluminium. A chief conclusion reached by Schofield is that acoustic emission consists of two distinct types: (1) random, low frequency, high amplitude bursts or pulses at low stresses; and (2) a continuous high frequency emission of initial low amplitude which increases in amplitude with increasing applied stress. Schofield also found that acoustic pulses are of extremely low energy, and amplifications of 106 to 107 are required for the detection of individual pulses. In some deformation processes avalanches of pulses may occur to produce a combined signal of much more energy.

Thus the possibility of acoustic emissions must be considered in connection with the large aluminium (or aluminium alloy) bars used for gravity-wave detectors. Many of these bars are suspended from their midpoints by steel cables or chains. Piezoelectric vibration detectors are usually placed around the bar circumference at the mid-point or sometimes on the ends. A distributed load resulting from the Earth's gravitational attraction acts on such a suspended bar of cross-sectional area A and length I with a value per unit length, F/I, =  $\rho gA$ , where  $\rho$  is the density and g is the gravitational acceleration. Bending moments around the plane of suspension will also

be present, and at the cross-sectional plane of suspension a shear stress of pgl exists. For a 2024-T4 aluminium bar of length 150 cm and diameter 19 cm, for example, this shear stress amounts to  $4.06 \times 10^5$  dyne cm<sup>-2</sup> (5.82 pounds inch<sup>-2</sup>). In addition, the bending moments will produce tension at the top of the suspension plane and compression at its bottom with mean stress values of around  $1.5 \times 10^7$  dyne cm<sup>-2</sup>; exact calculations of the stress distribution can be made, but are not needed to demonstrate that the 'gravitational' stress levels in the bars are sufficient to produce acoustic emission at the rate of several pulses per second. Further, and of particular interest regarding gravity-wave detectors, Schofield observed in 1958 (refs 20-22):

"... The influence of the material from the microphysical standpoint appears to be a prominent factor determining the characteristics of the emission signals. Although the specimens were prepared from the same stock and are assumed to be 'identical' from the engineering viewpoint, the emission sources, if originating at the microlevel in the material, would be affected by the actual metallurgical and physical differences occurring locally . . . ".

As suggested by equation (3) and confirmed by these experimental observations, bars of identical dimensions, chemical composition, and nominal structures may nevertheless 'emit' somewhat different audiofrequency vibrations under the same load because of differences in microstructures or initial stress states. In particular a narrow band or single-frequency vibration detector on one bar may record no signals because it is not tuned to any of the non-elastic mode frequencies corresponding to the characteristic microstructural length (or lengths), S, of that bar. A second bar, however, may have a non-elastic mode frequency identical to that of the detector frequency and display some of the audiofrequency bursts or 'events' which occur at very low stress levels.

Elaborate precautions taken to isolate the detector systems from ambient mechanical and sound vibration, shielding from electromagnetic radiation and so on, are all of little avail if possible vibrations generated within a detector bar are ignored.

Thus expectant observers of gravitational radiation should take into account their bar material microstates and the non-elastic vibration phenomena cited here.

I thank Leon Madansky and Stanley Corrsin for discussions.

# Palaeomagnetic evidence shows Malay Peninsula was not a part of Gondwanaland

#### M. W. McElhinny

Department of Geology, University of Canterbury, Christchurch, New Zealand

Palaeomagnetic results from Malaya show that the Malay Peninsula lay at 15° N during the late Palaeozoic, a result incompatible with the hypothesis that it once formed a part of Gondwanaland adjacent to India or Australia. Cretaceous results suggest the Peninsula was not at that time finally welded to the Asian mainland.

DEBATE has recently centred around the proposition that parts of South-east Asia were once a part of Gondwanaland. Burton¹ tried to explain the westerly origin of the sediments of northwest Malaya by supposing, in a reconstruction of Gondwanaland, that the west coast of the Malay Peninsula lay adjacent to

the east coast of India. His argument was supported by stratigraphic comparisons and the reasonably good fit of the coast-lines. Ridd² went one step further and fitted the whole of mainland South-east Asia and the Sunda shelf region between western Australia on the east, and the east coast of India on the west. This reconstruction was subsequently accepted by Audley-Charles et al.³ who incorporated it into their hypothesis of the development of eastern Indonesia. Stauffer and Gobbett⁴, however, raised serious objections to such a reconstruction from palaeoclimatic and other evidence. During the late Palaeozoic both India⁵ and Australia⁶ suffered continental glaciation and lay in high southern latitudes⁻. By contrast the

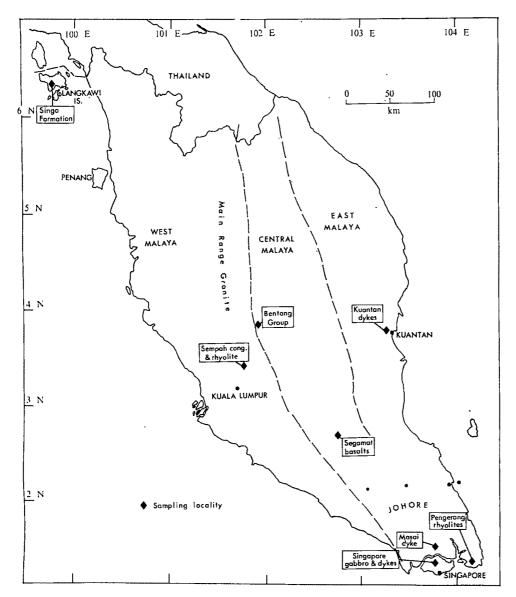

Fig. 1 Map of the Malay Peninsula showing sampling localities.

geological record of South-east Asia generally indicates tropical or subtropical conditions during the late Palaeozoic<sup>4</sup>. That the Permian of South-east Asia was laid down in warm water conditions is also accepted by Ridd<sup>8</sup>.

Both the palaeoclimatic problems and palaeogeographic reconstructions put forward can be tested using palaeomagnetic measurements. We report here the results of a reconnaissance survey of the palaeomagnetism of rocks of the Malay Peninsula. Some very preliminary results of this survey have already been reported.

Geology and sampling

The Malay Peninsula can be divided into three geologically distinct zones shown in Fig. 1. Since the first discovery of Lower Palaeozoic fossils by Jones<sup>10</sup> it has been found that Lower Palaeozoic rocks are restricted to the western zone. Recent work in Thailand<sup>11,12</sup> has recognised the extension of this western zone of Lower Palaeozoic rocks through peninsular Thailand into north-west Thailand and eastern Burma and northwards into Yunnan in China. This long geosynclinal belt has been referred to by Burton<sup>11</sup> as the Yunnan-Malay geosyncline. In the Malay Peninsula the boundary with the Lower Palaeozoic belt is approximately marked by the so-called Bentong Line<sup>13</sup>

which includes abundant radiolarian chert, some serpentine masses, metabasites and dolerite sills. It has been suggested that this marks the former position of a late Palaeozoic subduction zone<sup>14</sup>. The central zone is characterised by folded clastic Triassic–Jurassic carbonate and continental deposits whilst the eastern zone is composed of predominantly deep-water marine clastic Upper Palaeozoic rocks with patches of Upper Mesozoic continental deposits. The central and eastern regions are together considered by Stauffer<sup>15</sup> to be an island arc formed in late Palaeozoic times and welded on to the block to the west. The most recent summary of the geology of the Malay Peninsula

is given by Gobbett and Hutchison<sup>16</sup>. In the present study hand samples, oriented by Brunton compass, were collected from a number of sedimentary and volcanic formations and igneous intrusions ranging in age from Carboniferous to Cretaceous (Fig. 1).

Six samples of red muddy sandstone from the Bentong Group were collected between mileposts 75 and 76 on the road from Kuala Lumpur to Raub (3.8°N, 101.8°E). The dip of the beds ranges from 30° to 70°, and in this region they are overlain, apparently conformably, by fossiliferous Visean shales and sandstones<sup>27</sup>. The samples are thus probably Lower Carboniferous, although they could be older.

Three samples of laminated muddy sandstone were collected from the Singa Formation on the south-west part of Langkawi Island, off the north-west coast of the Malay Peninsula (6.2°N, 99.8°E). The formation covers the whole of the Carboniferous<sup>17</sup> and the stratigraphic position of the samples suggests they lie in the upper part of the Lower Carboniferous. The beds have an easterly dip of between 25° and 30°.

Twelve samples of reddish sandy mudstone were collected from the Sempah conglomerate together with seven samples of the overlying rhyolite in the Genting Sempah area on the Ulu Kali Road (3.4°N, 101.8°E). The rocks dip east at angles between 20° and 65°. Although inconclusive, Rb-Sr dating of the rhyolites<sup>18</sup> suggests they are most probably Early Permian in age with a maximum possible age of Late Carboniferous.

Ten samples were collected from rhyolites occurring at Pengerang in south-east Johore (1.4°N, 104.2°E). The lavas dip north-west at between 19° and 36°. Rb-Sr measurements on these samples suggest they are Early Triassic or Permo-Triassic in age. This is identical with the age of the south Johore and Singapore granites<sup>18</sup>, with which they are probably associated.

Ten samples of basalt and two of red agglomerate were collected from the Segamat basalts of Negri Sembilan (2.5°N, 102.8°E) described by Grubb¹³. The lavas lie unconformably on Middle to Upper Triassic rocks. The flows appear to dip in a south-westerly direction at 15°, although this dip may be in part original. A single, whole rock, K-Ar age determination from these basalts gives an age of 62 Myr (ref. 18) but this is regarded as a minimum age in view of demonstrated argon loss from other rocks in the region¹³. The basalts are probably Cretaceous in age.

Three samples were collected from basaltic dykes near Kuantan, Pahang (3.8°N, 103.3°E) and two from a dyke at Masai, Johore (1.5°N, 103.8°E). One of the Kuantan dykes gives a K-Ar age of 110 Myr and is therefore probably Cretaceous in age<sup>18</sup>.

One sample of gabbro and four samples, one from each of four thin dykes intruding the gabbro, were collected from two quarries on Singapore Island (1.3°N, 103.8°E). The gabbro is intruded by the Singapore granite of Early Triassic age<sup>18</sup> and basic dykes are not known to cut the granite. The dykes are

Solid symbols on the lower hemisphere, open symbols on the upper hemisphere.

Several specimens were cored and sliced from each hand sample and the natural remanent magnetisation was measured using a PAR-SM1 magnetometer. Pilot specimens were subjected to alternating field demagnetisation in increasing fields<sup>20</sup>. Most of these measurements were made at the Australian National University but during the final stages of this survey some additional measurements were made in the newly established palaeomagnetic laboratory in Kuala Lumpur. Measurements were then made on a Digico magnetometer and magnetic cleaning undertaken with a Schonstedt demagnetiser. In Canberra, pilot specimens of the sedimentary samples were also subjected to stepwise thermal demagnetisation in which the specimens were heated and cooled in a magnetic field of one γ (1nT) or less<sup>21</sup>.

probably of similar age to the gabbro which must be older than Early Triassic, but by how much is unknown, as there is no evidence which could define a maximum age.

#### Rb-Sr age of the Pengerang rhyolites

Four samples of Pengerang rhyolites were analysed as total rock samples at the Australian National University by the Rb-Sr method (see Table 1). The individual analyses show inadequate enrichment in radiogenic strontium to make reliable estimates

of age. A statistical analysis using the least-squares method with a two-error regression indicates an age of 238  $\pm$  23 Myr. The high mean square of weighted deviates (18.37) places this estimate in the category of a reconnaissance age determination, in so far as the samples probably had slightly different initial \*Sr/86Sr ratios; but the age can reliably be placed close to the Permo-Triassic boundary.

Bignell<sup>18</sup> obtained an isochron of  $225 \pm 6$  Myr for a combination of three analyses of Singapore granite and two of

 $k_b$   $K_b$  are precision parameters before applying tilt corrections and  $k_a$   $K_a$  are those after applying tilt corrections.

Johore granites, using a decay constant of  $1.47 \times 10^{-11}$  yr<sup>-1</sup>. Converted to the 1.39 decay constant used in our analysis, this result gives a figure of  $238 \pm 6$  Myr. Although this is also in the category of a reconnaissance result as the samples are from different localities, it is identical with that for the Pengerang rhyolites, which may provisionally be regarded as the effusive equivalent of the granites.

#### Palaeomagnetic results

Samples from the Bentong Group and Singa Formation responded well to thermal cleaning. Pilot specimens showed excellent stability up to the Curie Point of haematite. A small viscous component in the present field direction was removed at 300° C and on correcting for the dip of the strata, the samples group in a south-westerly direction with shallow inclinations (Fig. 2a). One sample was too weakly magnetised and its remanence could not be measured.

There was no difference in response of the red sediments from the Sempah conglomerate to either thermal or magnetic cleaning. Both the red sediments and rhyolite were therefore cleaned at 30 mT. Five of the twelve samples of red sediment, however, remained clustered about the present field direction, could not be cleaned and were rejected. This illustrates a problem associated with sampling red sediments in tropical countries. Even if samples are collected from road cuttings within a few years of exposure, weathering can have progressed fairly deep. In the case of red sediments it is sometimes very difficult to distinguish whether substantial deep weathering has occurred. Seven samples of red sandstone and seven rhyolites gave consistent directions after cleaning, similar to those given by the Bentong Group and Singa formations (Fig. 2b). All these late Palaeozoic samples are reverse magnetised.

The Pengerang rhyolites were extremely stable to alternating field demagnetisation, and blanket cleaning at 30 mT was carried out. One of the ten samples was normally magnetised and the other nine are reversed. The mean direction (Table 2, Fig. 2c) is very similar to that of the other late Palaeozoic groups. The basic rocks from Singapore and Johore and at Segamat and Kuantan were less stable than the rhyolites. One of

the Segamat basalts proved to be unstable but the remainder of the samples could be cleaned at 20 mT. The Segamat flows are all reverse magnetised whilst the red agglomerate and the dykes from Masai and Kuantan are normally magnetised

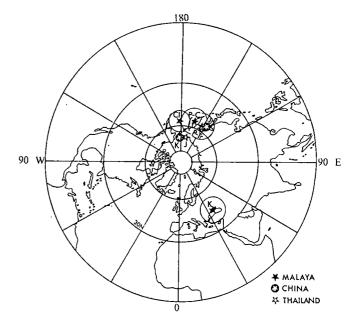

Fig. 3 Palaeomagnetic poles derived from the Malay Peninsula compared with those from China<sup>7</sup> and Thailand<sup>23</sup>.

(Fig. 2d). The Singapore gabbro and dykes are all reverse magnetised (Fig. 2e).

The mean direction of magnetisation for each of the groups is given in Table 2 together with the usual statistical parameters. The three late Palaeozoic means are very close to one another with only one of the 32 samples being normally magnetised.

Rock unit	Age	n	Lat. N	Long. E	K	$A_{95}$

Bentong Group and Singa formation	C(I)	8	57	182	37.0	9.2

n, No. of samples; K, precision parameter;  $A_{95}$ , radius of circle of 95% confidence about mean pole position.

Because of the different attitudes of the beds sampled, substantial tilt corrections have been applied. The statistical significance of the application of the fold test to four of the groups is given in Table 3 using the tables of McElhinny<sup>22</sup>. In spite of the relatively small collection of samples, there is a significant fold test for either the directions or poles for three of the four groups. This argues strongly for the stability of magnetisation of the samples at least since the time of folding, generally regarded as Late Triassic. The tilt corrections are too small for the Cretaceous group to produce any positive fold test. The presence of roughly opposed directions of magnetisation (Fig. 3d), however, provides additional stability evidence.

#### Palaeomagnetic poles and palaeogeography

Palaeomagnetic pole positions for four of the age groups are listed in Table 4. The five samples from Singapore are not considered sufficient to calculate a viable pole position and, in any case, the precise age of these rocks is not known. Between the Early Carboniferous and Early Triassic there appears to be a small westerly migration of the pole but it is hardly significant (Fig. 3). In fact, the data are such that it might be valid to combine all the 32 late Palaeozoic measurements together to

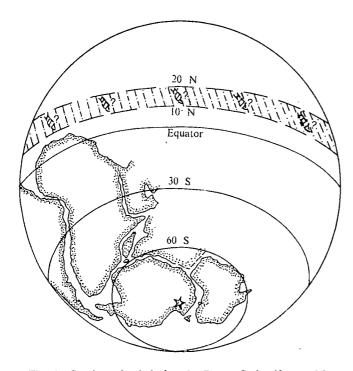

Fig. 4 Gondwanaland during the Permo-Carboniferous. The star is the mean palaeomagnetic south pole24. The Malay Peninsula must lie at 15°N, anywhere along the arc of a circle 105° from the pole. A 10° wide belt is shown together with some possible positions of the Peninsula.

produce an overall pole at 56°N, 165°E with  $A_{95} = 6.3$ °. The distribution of these poles changes from K = 6.1 to K = 17.1after correcting for the attitude of the beds, a change that is statistically highly significant<sup>22</sup>.

The palaeomagnetic poles are plotted in Fig. 3 where they are compared with poles from the Jurassic of Thailand<sup>23</sup> and the Jurassic and Cretaceous of China7. These lie fairly close to the Malayan late Palaeozoic poles but are well removed from the Malayan Cretaceous pole. This would suggest that the Malay Peninsula was not firmly attached to the mainland in Cretaceous times. The magnetic inclinations observed during the late Palaeozoic and Cretaceous in Malaya are very similar (Table 2) indicating that the Peninsula continuously occupied low latitudes of about 15°N during this time. This strongly supports the contention4 that the Malay Peninsula occupied low latitudes during the late Palaeozoic. Between the Permo-Triassic and the Cretaceous, the Peninsula underwent a clockwise rotation of 70° whilst maintaining much the same palaeolatitude.

The data for the late Palaeozoic may be used to test the hypothesis that the Malay Peninsula once formed a part of Gondwanaland. Since it is known that the late Palaeozoic is a period of predominantly reversed polarity<sup>7</sup> the data of Table 2 indicate that the Peninsula lay 105° away from the South Pole, that is, in the northern hemisphere at 15°N. Using the latest estimate of the Permo-Carboniferous pole with respect to Gondwanaland<sup>24</sup>, the Malay Peninsula must lie along a circle lying 105° away from this pole (Fig. 4). The palaeomagnetic data are clearly inconsistent with a position adjacent to India or Australia in the late Palaeozoic. Since Gondwanaland did not break up until the Jurassic, it seems unlikely that the Malay Peninsula was associated with the supercontinent in the early Palaeozoic and broke away before the other segments.

From Fig. 4 it can be seen that with due allowance for possible inaccuracies inherent in the method of positioning the Peninsula and Gondwanaland, the data do not completely rule out the hypothesis of Stauffer<sup>15</sup> that the Malay Peninsula may have been adjacent to parts of north Africa in the Palaeozoic. Further palaeomagnetic work planned for the Lower Palaeozoic of the Malay Peninsula may throw more light on this hypothesis.

Samples from the Singa Formation were collected by Dr P. H. Stauffer. Discussions with Drs C. S. Hutchison, P. H. Stauffer and T. E. Yancey were helpful. D. Edwards and P. Schmidt assisted with some of the magnetic measurements.

# Structural homology of myosin alkali light chains, troponin C and carp calcium binding protein

A. G. Weeds & A. D. McLachlan

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

Sequence comparison between the myosin alkali light chain, troponin C and carp calcium binding protein shows that the pattern of hydrophobic residues which forms the core of calcium binding protein is preserved in both troponin C and myosin alkali light chain. Strong structural similarities between the proteins are suggested. The role of gene duplication in the evolution of troponin C and myosin alkali light chain is discussed.

An understanding of the mechanism of muscle contraction at the molecular level requires knowledge of the structure of the proteins involved and the ways in which they interact. The only muscle protein whose three-dimensional structure is known is a calcium binding protein from carp (CBP), often called parvalbumin<sup>1,2</sup>. The function of CBP is unknown, but the amino acid sequence of the calcium binding component of rabbit troponin, troponin C (TNC)<sup>3</sup> is closely related<sup>4,8</sup> Collins<sup>6</sup> has observed a sequence homology between TNC and parts of the alkali light chains (ALC) of rabbit myosin<sup>7,8</sup>. We have made a more searching comparison between these proteins using the completed light chain sequence<sup>8</sup> to see how far the structural features of CBP are preserved in TNC and ALC. One aim was to try to discover why the free alkali light chains do not bind calcium and to account for the difference between the strong and weak calcium binding sites of TNC10. Another was to investigate the role of gene duplication in the evolution of these molecules<sup>1,11</sup>. Finally the general interest in the role of light chains in the function of myosin makes these comparisons pertinent.

#### Structural considerations

The characteristic features of CBP, established from the X-ray diffraction studies of Kretsinger<sup>2</sup>, may be summarised as follows. The protein contains two sites for binding calcium, related by a twofold symmetry axis. Each site lies in a corner between two helical regions, giving a basic structural unit; helix A-calcium site-helix B (abbreviated A-S-B). Duplication of this unit produces a two-unit structure (I-II) of the type A1-S1-B1-L-A2-S2-B2 (where L is a link region). CBP contains two additional helices at its N-terminal end and the packing of the six helices produces a hydrophobic core.

Figure 1a illustrates the structural features of carp CBP. Residues circled are buried in the core of the molecule<sup>2</sup> or make important hydrophobic contacts, and lines mark the main van der Waals' interactions. Figure 1a shows the pronounced asymmetry in the contacts between the four helices, such that the patterns of apolar groups are characteristically different. (In discussing these structures, a structural notation is used in which [A1(8)] refers to position 8 of helix A1.)

Ile [S(8)], (position 8 of the calcium site) is important structurally because of its buried side chain and a hydrogen bond linking the two adjacent Ile [S(8)] residues<sup>2</sup>. Phe [S1(7)] may screen calcium site 1 from water, whereas site 2 has a lysine residue at [S2(7)] and may be more exposed. The amino acids which coordinate to calcium (Fig 1a) are listed in Table 1.

Important structural features in the link region are the salt bridge between Arg [L12(5)] and Glu [A2(3)], in a crevice between helices B1 and A2, and two apolar interactions between Leu [B1(6)] and the main chain of Arg [L12(5)], and between Leu [12(7)] and Thr [A2(4)]. The internal residues Leu [B1(8)] and Val [B2(8)] both appear to interact with the two N-terminal helices. If the structure of TNC reflects that of CBP, these positions might form part of the hydrophobic core in contact with the structural units III and IV.

#### Sequence comparisons

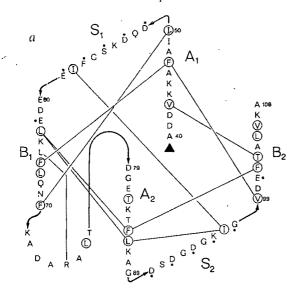

Comparison of TNC with CBP immediately suggested<sup>3</sup> that troponin C contains four units of the type A-S-B. This structure could arise by further duplication of the calcium binding components of CBP to produce a tetrahedral molecule of the form: (A1-S1-B1-L12-A2-S2-B2)-J23-(A3-S3-B3-L34-A4-S4-B4), with a new joining piece J23. Using the complete sequence of the alkali 2 light chain we have aligned the sequences using a computer program which compared sequences span by span, with a span size of 11 residues<sup>12</sup>. Similarities between amino acids were scored according to both their chemical similarity and the frequency of substitutions observed between them in a large number of different proteins. This procedure gives high scores for conservative replacements which fit readily into the same three-dimensional structure. The sequences of both TNC and ALC were compared with themselves as well as with each other, in order to identify internal repeats. Figure 1b and c shows the sequences drawn out to follow the structural features of CBP (compare Fig. 1a).

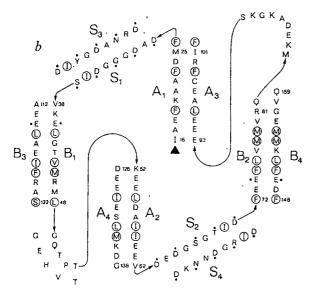

Table I Calcium co	ordinating	groups in	the calcium	i binding pro	tein, tropo	nin Cana e	quivalent p	ositions in t	he alkalı li	ght chains

X, Y and Z refer to the octahedral vertices of the calcium ligating positions, with the sequence positions indicated.
\*In CBP the Gly at position (-X) does not bind calcium, but the Asp at position (Y) links in both the Y and -X coordinating directions.

†In the (-Y) position, the carbonyl oxygen of the peptide bond coordinates to calcium.

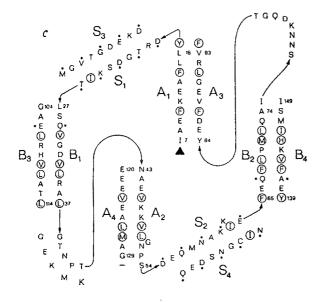

Fig. 1 a, Amino acid sequence of the two calcium binding structural units of carp calcium binding protein. Symbols AI, BI and so on are the helical segments, while SI and S2 denote the calcium binding sites. Residues circled are buried hydrophobic groups<sup>2</sup> or those making important hydrophobic contacts, and

The alignment of TNC with ALC is particularly good in the following regions: helix A1, the middle of helix B1 to L12 and the start of A2, A3, A4 and also the second half of S4 to the end of B4. As each sequence is repetitive there are also many cross-correlations, for example between TNC [L12] and ALC [L34] or vice versa.

The most striking observation is the preservation in both TNC and ALC of the pattern of hydrophobic residues which form the core of CBP. Table 2 summarises the data from Fig. 1, and shows that virtually every substitution is conservative. This suggests strong structural similarities between the three proteins. We have built a molecular model from Kretsinger's coordinates<sup>2</sup> to check that all the substitutions are feasible. Another residue which is conserved is the Glu at [A2(3)] and [A4(3)]. This is the position of the salt bridge in CBP, but the Arg in the link region is not present in either TNC or ALC. Link L34 of ALC contains two lysine residues, however, one of which might substitute in the salt bridge, while helices B1 and B3 of TNC and B1 of ALC contain arginine at position 9 which might preserve this bridge.

The only change required to fit both TNC and ALC to the CBP structure is to shorten the link region between helices B1 and A2, and B3 and A4. These links appear unnecessarily convoluted in the CBP model, and Pro [L12(4)] in both TNC and ALC could mark a bend which shortens this link. Also the glycine at the beginning of this region in both proteins could provide more flexibility at the start of the corner.

#### Internal repeats in TNC and ALC

Comparison of the sequence of TNC with itself shows clear evidence for internal repeats between structural units (I-II) and (III-IV), with unit I like III and II like IV, as observed by Collins et al.<sup>3</sup>. Helical regions which match particularly well are A2 with B4 (Fig. 1b). Such homologies are much stronger than those seen in normal proteins<sup>12</sup> and support the hypothesis of gene duplication in the evolution of this molecule. In ALC, the repeats follow a similar pattern but are much weaker. A surprising similarity which is not consistent with this pattern is the striking homology between A3 and B3 in TNC, which is analogous to that observed between helices A2 and B2 in CBP<sup>11</sup>. Again there are similar homologies in ALC, between A2 and B3 and between A3 and B2.

#### Calcium binding sites

Each of the four calcium sites of TNC and both sites of CBP contain four acidic residues within the six coordinating positions, (Table 1). Comparison of the TNC sites shows striking similarities between S3 and S4 which contain six identical residues and conserve a basic residue at position

the lines mark the main van der Waals' interactions. \*, Residues ligated to calcium ions; A, the start of the A1 helix is at residue 40 in the sequence, which follows the direction of the arrows to the C-terminal residue 108. For simplicity it has been assumed that each helix contains exactly 11 amino acids in every case. The one letter code for amino acids has been used in all the figures, where D=Asp, E=Glu, T=Thr, S=Ser, N=Asn, Q=Gln, K=Lys, R=Arg, H=His, G=Gly, A=Ala, V=Val, M=Met, I=Ile, L=Leu, Y=Tyr, F=Phe, P=Pro, C=Cys, and W=Try. b, Amino acid sequence of rabbit troponin C drawn out to correspond to the structural features of carp CBP, but with four calcium sites and four pairs of helices. A. The start of helix A1 corresponds to residue 16 in the sequence, while the C-terminus is at residue 159. c, Amino acid sequence of rabbit alkali light chain 2 drawn out as in b. A. The start of helix A1 corresponds to residue 7 in the sequence while the C-terminus is at residue 149. (The alkali light chain 1 has an additional 41 residues at its N-terminal end\*.) Other than residues 7 and 8 at the beginning of helix A1, its sequence is identical to that shown.

S(2). The match between S1 and S2 is less good although five residues are identical.

These two matches between the pairs of calcium sites S1-S2 and S3-S4 form a different pattern from that predicted on the basis of gene duplication, that is the members of each pair are more alike than S1 to S3 or S2 to S4. When the sequence of CBP was aligned with those of TNC and ALC simultaneously, structural unit II of CBP showed close resemblance throughout to TNC (IV) and ALC (IV). This is also evident in the comparisons between the calcium coordinating residues of S2 in CBP and S4 in TNC (Table 1). The calcium sites show other quite strong similarities: the tyrosine in the -Y coordinating position of TNC [S3] is comparable with phenylalanine in CBP [S1]. S1 of TNC is like S2 of CBP in having no acid group at position -X, whereas the Asp at position Y binds to calcium in both the Y and -X coordinating position (Table 1). There are five identical residues in the comparison of these two sites, but TNC [S1] contains an aspartic acid at position -Y, which makes this site unique.

Isolated ALC does not bind calcium under physiologically significant conditions, and there are less than four negatively charged groups in every 'site' of this protein (Table 1). Examination of the molecular model indicates other changes which might reduce the affinity for calcium by distorting the binding sites. For example, helix A2 would be disrupted by the extra glycine residue following Leu [A2(8)] and proline at [A2(10)], while proline [B2(6)] would distort this helix also. Furthermore, site S2 has an extra basic residue inserted in front of Ile [S2(8)]. Similarly the presence of bulky valine and methionine residues could block site S3. Thus it is not surprising that ALC fails to bind calcium ions with high affinity even though many of the structural features of the sites are apparently preserved.

Considering the four calcium binding sites of TNC in more detail, Potter and Gergely<sup>10</sup> have recently shown that isolated TNC contains two classes of calcium binding sites with different affinities. According to the CBP structural model, sites S3 and S4 are close together on either side of the approximate twofold axis at one end of the molecule, while sites S1 and S2 are close together at the other end. Sites S3 and S4 are most like the two sites of CBP, while S1 and S2 are more similar to one another than to either S3 or S4.

The most obvious interpretation of the sequences is that S3 and S4 have evolved into particularly strong binding sites, whereas S1 and S2 are weaker ones. But the structure suggests a more interesting possibility. There is evidence that the binding of calcium at the lower affinity sites of TNC switches 'on' muscle contraction and causes a conformational change in troponin (see ref. 13 for review). This suggests that during evolution the structure of the weaker binding sites acquired special constraints

which produced a lower affinity for calcium. The mechanism could then be similar to the binding of oxygen in haemoglobin, where the affinity of the haem groups is reduced by constraints in the tense deoxy structure14. On stereochemical grounds sites S1 and S2 which each contain two or more glycine residues, should be flexible and unconstrained with a high calcium affinity, while sites S3 and S4 would be more rigid and constrained. Also by analogy with CBP, site S3 with Tyr at S(7) is less exposed to solvent than site S4, which has Arg at S(7). Furthermore Site S4 has two basic groups at positions S(2) and S(7) whereas site S3 has only one. These facts suggest that site S4 may be the last to bind calcium and the first to release it, since the basic residues might weaken the calcium affinity of this site. It should be remembered, however, that the calcium affinities are altered in the complete troponin complex.

#### Gene duplication

The hypothesis that both TNC and ALC arose by two successive duplication events, producing first a dimeric structure and then a tetrameric one, is confirmed by Collins' analysis<sup>3,6</sup>, and by our own computations. This is most clearly seen from the similarity between structural units I and III of TNC and between helices B2 and B4. The repeats are much stronger in TNC than ALC, suggesting that TNC is closer to the primitive sequence. CBP could then have exolved by adding two extra helices to the primitive dimeric unit¹ or by degradation of the tetrameric structure (I-II-III-IV) to (II-III-IV). The latter seems more likely since sites S1 and S2 of CBP closely resemble sites S3 and S4 of TNC, and the first helix of CBP is noticeably similar to the A helices of TNC. (The sequence of this helix is Asp-Ala-Ala-Ala-Ala-Leu-Glu-Ala-Cys.)

Proteins with a repeating sequence of the type X-X' and an approximate twofold axis are quite common, and probably often evolve from a structural dimer X:X. If an arbitrary structure X duplicates, it is highly improbable that the two halves of structure will fit together, and a good fit would require rapid evolution independently in the two halves leading to a structure  $X_1-X_2$ , with  $X_1$  rather different from X2. But if X evolves to form a well fitting dimer X:X before the duplication, the duplicated molecule X-X requires few modifications and the two halves can remain very similar. One suggestive example is the ferredoxin of Peptococcus aerogenes15, where the polypeptide chain has two repeat units and there are two similar iron binding sites formed by clusters of sulphydryl groups. Surprisingly each site is formed by groups from both halves of the sequence, so that dimer formation is essential for iron binding to occur. It is therefore probable that the halfchain units evolved the power to interact before duplication produced a 'single chain dimer'. Applying this principle to TNC leads to the suggestion that a primitive unstable

Helix residue no.	Helix Al			Helix A3		Helix B1			Helix B3	
	CBP	TNC	ALC	TNC	ALC	CBP	TNC	ALC	TNC	ALC
4	Val	Phe	Phe	Leu	Phe	Leu	Leu	Val	Leu	Leu
7	(Ala)	(Ala)	(Ala)	(Cys)	(Gly)	Phe	Val	Val	Ile	Val
8	Phe	Phe	Phe	Phe	Leu	Leu	Met	Leu	Phe	Leu
11	Ile	Phe	Tyr	Phe	Phe	Phe	Leu	Leu	(Ser)	Leu
		Helix A2 • •			Helix A4		Helix B2			Helix B4
	CBP	TNC	ALC	TNC*	ALC	CBP	TNC	ALC	TNC	ALC
1	(Asp)	(Lys)	(Asp)	(Asp)	(Glu)	Val	Phe	Phe	Phe	Tyr
4	(Thr)	Leu	Val	He	Val	Phe	Phe	Phe	Phe	Phe
5	(Lys)	(Asp)	(Lys)	(Glu)	(Glu)	(Thr)	Leu	Leu	Leu	Val
7 .	Phe	Ìle	Val	Leu	Leu	Leu	Mct	Met	Met	(His)
8	Leu	Ile	Leu	Met	Met	Val	Met	Leu	Met	Ile

The hydrophobic residues shown are those which play an important part in holding the helices and calcium sites together in the CBP structure. Residues in brackets are not hydrophobic, and demonstrate the asymmetry of the patterns of hydrophobic groups in the different helices.

structure of the type A-S-B was originally stabilised by formation of a dimer, and gene duplication subsequently yielded the two-unit structure (A-S-B)-L-(A-S-B). The similarity between helices A and B which has already been noted could be accounted for if the (A-S-B) unit itself was formed from a single precursor helix H and a piece of polypeptide chain, C. Dimenisation of H-C to stabilise the helices, followed by gene duplication would lead to H-C-H-C, the precursor of (A-S-B).

#### Light chain function

If carp calcium binding protein, rabbit troponin C and the alkali light chains have similar three-dimensional structures, they may also have related functions. While the function of TNC is most clearly understood, the role of CBP remains obscure<sup>16</sup>. The presence of parvalbumins in skeletal muscles of higher ventebrates may indicate a calcium binding role directly related to muscle contraction17. There is no evidence to support any calcium binding role for the alkali light chains, and isolated light chains do not bind calcium in the concentration range  $10^{-7}$  M to  $10^{-5}$  M in the presence of 1 mM Mg2+ ions (J. Kendrick-Jones, personal communication). Thus in spite of the structural similarity, this protein may have lost an original function related to calcium binding and now possess an entirely different function, possibly connected with the ATPase activity of myosin. Experiments to demonstrate participation of these light chains in the ATPase activity of skeletal myosin18,19 have given variable results and cannot be regarded as conclusive. The reaction of the disulphide analogue of ATP with the single thiol group in the S4 corner of ALC is suggestive but not conclusive, since other thiols in the heavy chains are also labelled20.

Interest in the effects of calcium on myosin has been increased by the discovery that calcium regulation in molluscan muscles depends on a specific light chain associated with the myosin 'heads' (the EDTA light chain of scallop myosin)21. Thus mammalian muscle appears to have evolved a different form of calcium regulation, though the discovery of species with dual regulation22 has led to the speculation that vertebrate muscle might also contain a myosin regulatory system. X-ray evidence suggests a direct effect of calcium on vertebrate myosin23,24 and biochemical studies have sought to confirm this25,26. Kendrick-Jones has recently shown that of the three light chains present in rabbit myosin, one (the DTNB light chain) can substitute for the EDTA light chain of scallop myosin and restore calcium sensitivity to the desensitised myosin<sup>27</sup>. Thus this light chain acts as an inhibitor to switch 'off' the scallop actomyosin ATPase when calcium is removed. This suggests that the DTNB light chain is analogous to troponin I in the actin-linked regulatory system rather than troponin C. It is now important to establish whether the DTNB light chain has an equivalent inhibitory function in mammalian myosin and whether, in living muscle, the alkali light chains have any function related to calcium regulation.

We thank Drs H. E. Huxley and J. Kendrick-Jones for critical reading of this manuscript and helpful discussions. Note added in proof: Tufty and Kretsinger28 have kindly sent us a draft of their paper in which they have interpreted the ALC sequence in terms of three "EF hands". These three correspond to sites 1, 3 and 4 in Fig. 1c.

## An SV40-induced initiation factor for protein synthesis concerned with the regulation of permissiveness

Katsuhisa Nakajima, Hideo Ishitsuka & Kin-ichiro Oda

Department of Tumor Virus Research, Institute of Medical Science, PO Takanawa, Tokyo 108, Japan

An SV40-induced factor, which catalyses binding of late human adenovirus mRNA to ribosomes to form the 80S initiation complex for protein synthesis, is present in high salt extracts of ribosomes from the transformed simian cells. THE defective step of human adenovirus growth in African green monkey kidney (AGMK) cells seems to reside in the inability of ribosomes to bind with late viral mRNA for capsid proteins to form polyribosomes, since certain species of late viral mRNA are absent in polyribosomes of the infected cells

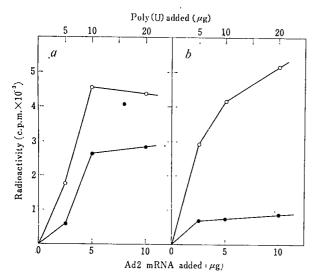

Fig. 1 Response of preincubated S30 to added RNA. The cells were washed with Earle's solution and suspended in 2 vols of TKM (10 mM Tris-HCl, pH 7.4, 10 mM KCl, 1.5 mM Mg (OAc)<sub>2</sub>) at 0° C for 10 min. The swollen cells were disrupted by about 20 strokes of a Dounce homogeniser and the tonicity was immediately restored by the addition of 1/3 vol. of tenfold concentrated medium K(1 × medium K contains 30 mM Tris-HCl, pH 7.4, 120 mM KCl, 5 mM Mg(OAc)<sub>2</sub> and 3 mM dithiothreitol (DTT)). The homogenate was centrifuged at 1,000g for 5 min to remove nuclei and the supernatant was centrifuged at 30,000g for 10 min. The supernatant (S30) was supplemented with 5 μM each of 20 amino acids, 5 mM ATP, 0.5 mM GTP, 6 mM phosphoenolpyruvate (PEP), 10 μg ml<sup>-1</sup> of pyruvate kinase and incubated at 37° C for 50 min. The incubated S30 was centrifuged at 10,000g for 5 min and the supernatant was dialysed against medium K. The reaction mixture (0.15 ml) for amino acid incorporation contained 50 μl of preincubated S30, 1 mM ATP, 0.1 mM GTP, 10 mM PEP, 0.2 mg ml<sup>-1</sup> of pyruvate kinase, 20 μM of 19 naturally occurring L-amino acids (minus phenylalanine or leucine) and 1μCi ml<sup>-1</sup> of <sup>3</sup>H-phenylalanine (10 Ci mmol<sup>-1</sup>) or <sup>3</sup>H-leucine (32 Ci mmol<sup>-1</sup>) in the presence of either poly(U) (○) or Ad2 mRNA (●). The mixture was incubated at 37° C for 1 h and the hot trichloroacetic acid (TCA)-insoluble count was measured. a, T22 cell S30; b, C14 cell S30.

although they are present in the cytoplasm<sup>1</sup>. This defect, however, can be complemented either by coinfection or transformation of the cells with SV40, indicating that a factor(s) is induced by SV40 which might enable the ribosomes to bind with this species of late adenovirus mRNA.

Initiation of protein synthesis in *Escherichia coli* requires three factors (F1, F2 and F3)<sup>2-5</sup> that associate with ribosomes, and similar factors (M1, M2 and M3)<sup>6-8</sup> have been found in mammalian cells. Of these, F3 (M3) is concerned with mRNA selection by ribosomes and, therefore, has the regulatory function of deciding the species of mRNA to be translated. The function of this factor can easily be modified as has been demonstrated in *E. coli* after infection with phage T4 (ref. 9), T7 (refs 10 and 11) or MS2 (ref. 12).

Here we show that a factor(s) is present in the high salt extract of ribosomes from SV40-transformed AGMK cells which are permissive for human adenoviruses, but not in ribosomes from untransformed AGMK cells which are non-permissive. The factor enables ribosomes to bind with late adenovirus mRNA and to form the 80S initiation complex for protein synthesis. We discuss a mechanism of induction of this factor by SV40 in relation to the mechanism of cell transformation by oncogenic viruses.

#### Response of preincubated S30 to added RNA

Differential response to RNA of ribosomes prepared from SV40-transformed AGMK cells, clone T22 (ref. 13), and untransformed AGMK cells, clone C14 (ref. 13), was compared by protein synthesis with preincubated S30 in response to either late adenovirus type 2 (Ad2) mRNA or poly(U). Late Ad2

mRNA was prepared as poly(A)-containing RNA from polyribosomes of the infected KB cells as reported previously<sup>1</sup>. The RNA was sedimented in an SDS-sucrose gradient and the 24S region was collected because the size of mRNA for hexon, a major component in adenovirus capsid proteins, was estimated as 24S on the basis of the molecular weight of hexon, 130,000 (ref. 14). A certain species of mRNA of this size is apparently absent from polyribosomes of the adenovirusinfected C14 cells but present in the infected T22 cells<sup>1</sup>. As shown in Fig. 1, C14 cell S30 translates late Ad2 mRNA very poorly by comparison with T22 cell S30, whereas both translate poly(U) with almost the same efficiency. A slight incorporation of amino acids by C14 cell S30 in response to late Ad2 mRNA is probably caused by contamination of cellular mRNA, although poly(A)-containing RNA separated on poly(U)-Sepharose consists predominantly of Ad2 mRNA as described previously1. The gel electrophoretic analysis of the products (Fig. 2) showed that hexon was synthesised with T22 cell S30 in response to late Ad2 mRNA but not with C14 cell S30. These results indicate that a factor(s) responsible for translation of certain species of late Ad2 mRNA is present in SV40-transformed AGMK cells but not in untransformed AGMK cells.

#### Formation of 80S initiation complex

The presence of an initiation factor which catalyses binding of late Ad2 mRNA to ribosomes in the high salt extract of ribosomes (ribosomal wash) from SV40-transformed AGMK cells was demonstrated by formation of the 80S initiation

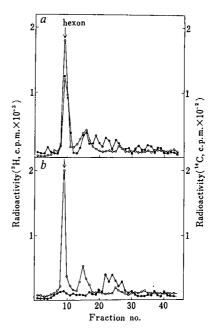

Fig. 2 Gel electrophoretic analysis of product synthesised with S30. Protein synthesis with S30 in response to late Ad2 mRNA was carried out as described in Fig. 1, except that ³H-leucine and 19 cold amino acids were replaced by ¹⁴C-amino acid mixture. After the reaction, pH was adjusted to 11.0 by the addition of 0.1 N NaOH and the mixture was incubated at 37° C for 15 min. The mixture was dialysed against 0.1 M sodium phosphate (pH 7.4) containing 0.1% SDS and 0.01% 2-mercaptoethanol overnight. The products were concentrated by evaporation at 37° C in dialysis tubing and Ad2 virions labelled with ³H-amino acids mixture were added. After heating at 100° C for 1 min, the products were subjected to electrophoresis. Electrophoresis was carried out on 7.5% polyacrylamide gel (10×0.6 cm) at 80 V (15 mA per gel) for 4 h. The buffer used was 0.05 M sodium phosphate (pH 7.2) containing 0.1% sodium dodecyl sulphate (SDS). Gels were then sliced and the slices were counted in 5 ml of Triton X-toluene scintillator after dissolution in 0.5 ml of 50% H<sub>2</sub>O<sub>2</sub> at 80° C overnight. a, T22 S30; b, C14 S30. ♠, ¹⁴C; ○, ³H.

complex for protein synthesis. Ribosomes washed with 0.5 M KCl were prepared from preincubated C14 cells S30. High salt extract of ribosomes was prepared from cells either permissive or non-permissive to adenoviruses. Met-tRNA<sub>f</sub> was prepared by charging methionine to tRNA from T22 cells with *E. coli* S100.

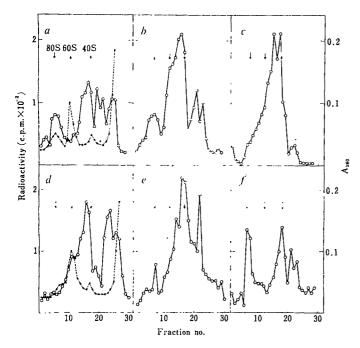

Fig. 3 Formation of the 80S initiation complex with Ad2 mRNA. Ribosomes were prepared from the preincubated C14 cell S30. The S30 was treated with sodium deoxycholate (0.8%) and centrifuged at 16,000g overnight through a cushion of 60% sucrose in medium K at 4° C. The pellet was suspended in 1 ml of 50 mM triethanolamine-HCl (TEA), pH 7.6, containing 0.5 M KCl, 1.5 mM Mg(OAC)2 and 1 mM puromycin²2 and incubated at 0° C for 10 min followed by incubation at 37° C for 10 min. It was centrifuged through a 10-30% (w/w) sucrose gradient in 50 mM TEA, pH 7.6, containing 0.5 M KCl and 5 mM Mg(OAC)2 at 23,000 r.p.m. for 16 h at 4° C in a Spinco SW 25.1 rotor. The 40S and 60S ribosomal subunits, collected separately from the gradient, were stored at 0° C in medium K containing 20% glycerol after centrifugation at 16,000g for 5 h. Ribosomal wash fraction was prepared from crude ribosomes obtained from the preincubated S30. Ribosomes were gently stirred for 1 h at 0° C in 0.25 M sucrose containing 50 mM Tris-HCl, pH 7.4, 10 mM MgCl2, 1 M KCl, 2 mM DTT, 10 mM 2-mercaptoethanol and centrifuged at 200,000g for 4 h at 4° C through a cushion of 0.5 M sucrose in the same solution. The top supernatant was dialysed overnight against 80% ammonium sulphate in 50 mM Tris-HCl, pH 7.4, containing 50 mM KCl, 0.1 mM EDTA, 10 mM 2-mercaptoethanol and 5% glycerol dialysed against the same buffer for 4 h at 0° C and stored at —80° C. Transfer RNA was prepared from T22 cells and amino-acylated by S100 extract of E. coli. Formation of the 80S initiation complex was carried out in four successive incubation steps according to Levin et al. The components added in each reaction step were dissolved in 40 mM Tris-HCl, pH 7.4, containing 1 mM DTT and 0.4 mM GTP. Each reaction was carried out at 37° C for 5 min. Step 1; (0.1 ml) 30 pmol of Met-tRNA, 75µg of ribosomal wash proteins, 0.1 M KCl. Step 2: (0.1 ml) 0.25 A<sub>280</sub> units of 40S subunits, 80 mM KCl and 5 mM MgCl2. Step 3: (0.05 ml) 9.1 Helabelled late Ad2 mRNA (about 5,000 c.p.m.), 65 mM KCl an

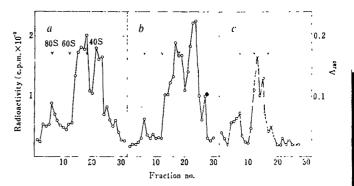

Fig. 4 Formation of the 80S initiation complex with SV40 mRNA. Formation of the initiation complex was carried out as described in Fig. 3. Ribosomal wash proteins (75 µg) used were prepared from: a, T22 cells; b, C14 cells; c, GC7 cells. SV40 mRNA was prepared as poly(A)-containing RNA from polyribosomes of the infected GC7 cells at 48 h after infection as previously described.

The binding of mRNA to ribosomes was carried out with either 3H-labelled late Ad2 or SV40 mRNA in four successive incubation steps according to Levin et al.15 (Figs 3 and 4). Late Ad2 mRNA prepared from KB cell polyribosomes forms the 80S initiation complex with T22 and KB cell ribosomal wash (Fig. 3a and b) but not with GC7 and C14 cell ribosomal wash (Fig. 3c and d); GC7 cells are also a line of AGMK cells, non-permissive to adenoviruses. A small shoulder observed at 80S in Fig. 3c and d may indicate the presence of a small amount of cellular mRNA in Ad2 mRNA preparation. The ribosomal wash prepared from a permissive monkey kidney cell line, Vero cells, formed a smaller amount of the 80S complex (Fig. 3e), which may reflect the lower susceptibility of Vero cells to adenovirus infection than KB and T22 cells. Late Ad2 mRNA prepared from the cytoplasm of infected C14 cells formed the complex with the T22 cell ribosomal wash with the same efficiency as late Ad2 mRNA prepared from polyribosomes of the infected KB cells (Fig. 3f) indicating the functional integrity in formation of the 80S complex of late

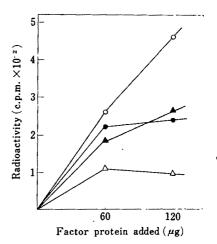

Fig. 5 Formation of methionyl-puromycin. The reaction mixture (0.3 ml) for formation of the 80S initiation complex containing <sup>3</sup>H-met-tRNA (about 50 pmol, 20,000 c.p.m.) and either 8 μg of late Ad2 mRNA or 20 μg of poly(AUG) (Sigma) was incubated at 37° C with increasing amounts of ribosomal wash proteins as described in Fig. 3. Puromycin was then added to a final concentration of 1 mM (final volume 0.5 ml) and incubation was continued at 37° C for 30 min. The reaction was terminated by the addition of 0.5 ml of 0.2 M sodium phosphate buffer (pH 8.1) and <sup>3</sup>H methionyl-puromycin was extracted<sup>23</sup> with 1.5 ml of ethyl acetate saturated with the same buffer. An aliquot (1 ml) of the ethyl acetate layer was counted in 10 ml of Bray's scintillator. O, Ad2 mRNA, T22 cell ribosomal wash; Δ, Ad2 mRNA, C14 cell ribosomal wash; Φ, poly(AUG), C14 cell ribosomal wash.

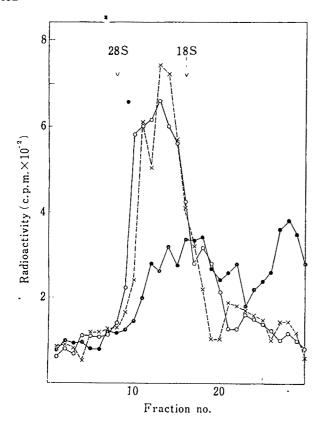

Fig. 6 Size distribution of late Ad2 mRNA after binding reaction. The reaction for formation of the 80S initiation complex with 3H-labelled late Ad2 mRNA was carried out as described in Fig. 3 with ribosomal wash proteins from either T22 cells (O) or C14 cells (•). The reaction was terminated by the addition of 0.5% SDS and the mixture was centrifuged in a 15-30% (w/w) SDS-sucrose gradient at 24,000 r.p.m. for 18 h at 28° C in a Spinco SW 25.1 rotor. Each fraction was counted after TCA precipitation. ×, 3H-labelled late Ad2 mRNA was centrifuged without reaction.

Ad2 mRNA transcribed in non-permissive monkey cells. The formation of the complex depended on Met-tRNA<sub>f</sub>. The inability of C14 and GC7 cell ribosomal wash to bind late Ad2 mRNA to ribosomes does not result from an inactivation of factor proteins. The 80S initiation complex with SV40 mRNA was formed with ribosomal washes from C14 and GC7 cells which are permissive to SV40 (Fig. 4). The ribosomal washes from T22 and C14 cells facilitated binding of poly(U) to ribosomes at low concentrations of Mg2+ with the same efficiency, indicating that both ribosomal washes contain initiation factors M1 and M2. The mRNA-protein complex slightly larger than 40S was formed with the ribosomal wash from both permissive and non-permissive cells (Figs 3 and 4). It is not yet clear whether this complex is the 40S initiation complex or the ribonucleoprotein particle formed between late Ad2 mRNA and proteins in the ribosomal wash.

#### Functional integrity of 80S complex

To demonstrate that the 80S complex formed with late Ad2 mRNA is active in the initiation of protein synthesis, the formation of methionyl-puromycin (met-puro) in the reaction mixture with the ribosomal wash from both T22 cells or C14 cells was examined. Formation of met-puro increased linearly with increasing amounts of T22 cell ribosomal wash (Fig. 5), whereas with C14 cell ribosomal wash it reached a plateau after a small increase. This difference was not observed when late Ad2 mRNA was replaced with poly(AUG). Addition of 120 μg each of C14 and T22 cell ribosomal wash to the binding mixture did not alter the amount of met-puro formed by T22 cell ribosomal wash alone, indicating that an inhibitor of the formation of either the intiation complex or dipeptide is not present in C14 cell ribosomal wash. The stability of late Ad2 mRNA during the binding reaction was studied by examining the alteration in its size. The size distribution of late Ad2 mRNA in an SDS-sucrose gradient after the binding reaction with T22 cell ribosomal wash was the same as that of nonincubated late Ad2 mRNA (Fig. 6), whereas the binding reaction with C14 cell ribosomal wash resulted in the degradation of late Ad2 mRNA. RNase activity in the ribosomal wash was low and not significantly different for C14 and T22 cells. These results indicate that formation of the functional complex with ribosomes protects mRNA from degradation and that the factor present in the ribosomal wash of T22 cells is specific for late Ad2 mRNA.

#### Genesis and biological significance

These results provide the first evidence that the permissiveness and non-permissiveness of the cells to virus infection is regulated at the initiation of protein synthesis. They also offer a good system for characterising the nature of the initiation factor M3. Appearance of a new initiation factor responsible for late Ad2 mRNA translation in SV40-transformed simian cells may be the result of either modification of a pre-existing M3 factor or induction of a new M3 factor by the SV40 gene function. The SV40 helper function for growth of human adenoviruses in monkey cells is one of the virus early functions, since an early mutant of SV40, tsA7 (ref. 16), defective in virus DNA replication, expresses this function at the non-permissive temperature. An adeno 2-SV40 hybrid virus, Ad2+ND1 (refs 17 and 18) in which only 18% of the SV40 DNA is integrated into Ad2 DNA, expresses the SV40 function to induce U antigen and to support adenovirus growth in simian cells. The factor itself may not be coded by the SV40 genome, however, as the early region estimated by hybridisation competition is too small<sup>19,20</sup> to code various proteins and the SV40 induced-U antigen is localised in the nuclei of the infected cells. The factor may be synthesised as a result of derepression of the host cell genome by some unknown SV40 early gene product. Our findings indicate that the efficiency of the helper function in supporting synthesis of Ad2 virion antigen in simian cells previously infected with SV40 (24 h before infection of adenoviruses) depends on the multiplicity of SV40 infection and correlates with the efficiency of induction of cellular mRNA synthesis. The alteration of ribosomes in the SV40-infected simian cells so as to respond to late Ad2 mRNA to synthesise hexon is also multiplicity-dependent. These results support the assumption that the derepression of the cellular function is involved in the helper function. Derepression of the cellular function by SV40 may cause the pleiotropic changes in the cells which would result in the alteration of various cellular systems, such as the cell surface structure21 and the protein-synthesising system, causing the cell to become malignant.

We thank Dr H. Shimojo for support and Drs Y. Kaziro and K. Iwasaki for discussions. This work was supported by research grants from the Ministry of Education of Japan.

# **Echinomycin:** a bifunctional intercalating antibiotic

M. J. Waring & L. P. G. Wakelin

Department of Pharmacology, Medical School, Hills Road, Cambridge CB2 2QD, UK

The interaction between echinomycin and circular DNA or sonicated rod-like DNA fragments shows that this antibiotic binds by a bifunctional mode of intercalation. Binding parameters for a variety of natural and synthetic DNAs vary widely, indicating that echinomycin interacts selectively with specific nucleotide sequences.

THE significance of twofold symmetry in the structures of small molecules which bind to DNA, itself characterised by a dyad axis of symmetry perpendicular to the helix axis, was emphasised by Sobell et al.1 in their model for actinomycin-DNA binding derived from a crystallographic study of a 1:2 actinomycindeoxyguanosine complex. Subsequent work has shown the importance of symmetry-related elements in the recognition of DNA sequences by repressors<sup>2,3</sup>, restriction enzymes<sup>4</sup> and possibly transcriptional factors4.5, suggesting that principles of symmetry may prove to be a general feature of recognition processes involving DNA.

We were struck by the apparently perfect symmetry in the structure of the antibiotic echinomycin<sup>6</sup> proposed by Keller-Schierlein et al.7. Echinomycin has long been known to bind to DNA<sup>8,9</sup> but the nature of its interaction has remained obscure. It is an extremely potent inhibitor of RNA synthesis<sup>8-10</sup>, some

four to five times more potent than actinomycin D in vivo10, and there is every indication that its antitumour and other biological activities result from its binding to DNA<sup>11</sup>. During the course of our work, proton magnetic resonance studies<sup>32</sup> suggested that echinomycin contained four more hydrogen atoms than expected from the published structure?. While the revised structure (Fig. 1) retains a twofold axis of rotational symmetry for the cyclic octapeptide dilactone and its attached quinoxaline-2-carboxylic acid chromophores, the sulphur-containing cross-bridge (replacing the dithian ring originally proposed<sup>7</sup>) introduces an element of asymmetry. In respect of this pseudo-symmetrical appearance, as well as the sequence of amino acid residues in the two halves, there are obvious parallels with the structure of actinomycin1.

#### Specificity for double-helical DNA

Echinomycin is much less soluble in purely aqueous systems than actinomycin, which necessitated the development of a novel solvent-partition method to investigate its binding to nucleic acids. Representative results, full details of which will be published elsewhere, are shown in Fig. 2. These curves reveal that the binding is completely specific for DNA, not RNA, that single-stranded or heat-denatured DNAs bind less antibiotic than intact double-helical DNA, and that complete disruption

1 Structure of echinomycin. Abbreviations: MeVal, methylvaline; Ser, serine; Ala, alanine; Cys, cysteine; DiMe-L- Cys, N,S-dimethyl-L-cysteine. The formula is a revision of that published previously7, based on new results from mass spectrometry and nuclear magnetic resonance spectroscopy32.

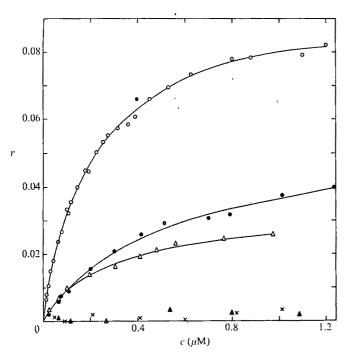

Fig. 2 Interaction between echinomycin and nucleic acids. The buffer (SHE) contained 2 mM HEPES, 10 μM EDTA and 9.4 mM NaCl (pH 7.0 at 20° C; total ionic strength 0.01). Portions (3 ml) of nucleic acid solutions (182 μM with respect to nucleotides) were shaken together with 4 ml of echinomycin dissolved in iso-amyl acetate for 2 h at 20.0° C to establish equilibrium. The phases were then separated by centrifugation at 2,000 r.p.m. for 30 min in an MSE Super Minor centrifuge. The free antibiotic concentration in the aqueous phase (c) was determined from the absorbance of the organic phase at 315 nm measured in a 40 mm light path semimicro cuvette, based on a molar extinction coefficient of 1.15 × 10⁴ for echinomycin in iso-amyl acetate and its partition coefficient between this solvent and SHE buffer (8.93 ± 0.32 × 10<sup>-3</sup> at 20° C). The total antibiotic concentration in the aqueous phase was determined by measuring the absorbance at 325 nm after dissociating the complex by addition of an equal volume of dimethyl sulphoxide (DMSO). In 50% (v/v) DMSO-buffer mixtures the molar extinction coefficient was determined to be 1.24 × 10⁴ at 325 nm irrespective of the nucleic acid concentration. The concentration of bound echinomycin was obtained by difference and expressed in terms of r, mol antibiotic bound per mol of nucleotides. O, Native calf thymus DNA sheared to produce fragments of approximately 18S free from single-stranded ends by the method of Pyeritz et al.³0; ♠, single-stranded circular DNA from bacteriophage fd; △, calf thymus DNA denatured by rapid cooling; ♠, calf thymus DNA denatured by rapid cooling; ♠, calf thymus DNA denatured in the presence of 1% formal-dehyde; ×, total ribosomal RNA from E. coli B.

of secondary structure by denaturation of DNA in the presence of formaldehyde abolishes the binding altogether. A Scatchard plot of the data for calf thymus DNA yielded a straight line up to an revalue (antibiotic molecules bound per nucleotide) of about 0.06; the slope and intercept of this line gave an apparent association constant  $K_{\rm ap}$  of  $6.0\pm0.3\times10^6$  M<sup>-1</sup> and the number of sites per nucleotide (n) as 0.087, equivalent to one binding site per six base pairs in this DNA. Values of  $K_{ap}$  and n for the heat-denatured DNA were  $4.0\pm0.4\times10^8$  M<sup>-1</sup> and 0.032, respectively; for fd DNA they were 2.2±0.2×10<sup>6</sup> M<sup>-1</sup> and 0.053. These parameters, two to three times lower than those for the native double-helical DNA, undoubtedly reflect the limited interaction between echinomycin and 'hairpin' helical segments present in the single-stranded DNAs; witness the lack of interaction after formaldehyde treatment. These results corroborate the qualitative conclusions of earlier workers8,9 and compare well with parameters reported for the binding of actinomycin to DNA<sup>12,13</sup>.

#### Bifunctional intercalation

The quinoxaline chromophores of echinomycin are similar in size to the quinoline chromophore of chloroquine, which is

known to bind to DNA by intercalation<sup>11,15</sup>. Their symmetrical disposition with respect to the octapeptide ring, together with the apparent structural and functional resemblance between echinomycin and actinomycin, suggested that both chromophores might be capable of intercalation, in a symmetry-related fashion, at the same time. A double-intercalation event would be expected to result in twice the unwinding of the helix caused by binding of a monofunctional intercalating agent<sup>15</sup>, twice the extension along the helix axis<sup>16</sup>, and markedly enhanced binding to negatively superhelical circular DNA at low values of r (ref. 17). These predictions have been verified.

Figure 3 compares the unwinding of the helix associated with binding of echinomycin to that caused by ethidium, an established (monofunctional) intercalating drug<sup>15.18.19</sup>. Echinomycin removes and reverses the supercoiling of circular PM2 DNA in decisive fashion, with an equivalence binding ratio<sup>15</sup> of 0.028 ± 0.004 antibiotic molecules bound per nucleotide. Under the same conditions equivalence occurs with 0.051 ±0.007 ethidium molecules bound per nucleotide. Thus the helix-unwinding angle of echinomycin is 1.82 ±0.30 times that of ethidium, or 21.9° per bound antibiotic molecule if the estimate of 12° unwinding for ethidium<sup>18</sup> is accepted<sup>15.19</sup>. This is the first time a drug has been found which unwinds the DNA helix by an angle larger than does ethidium, the actual value being almost double.

Figure 4a shows the extension of the helix caused by binding of echinomycin,  $1.87\pm0.05$  times the theoretical extension of 3.35 Å required to accommodate a single aromatic ring system, corresponding to a lengthening of about 6.3 Å per bound antibiotic molecule. Comparable experiments with proflavine and ethidium were reported to yield a value of  $2.7\pm0.2$  Å (refs 16 and 20). Again the value for echinomycin is twice as high.

Figure 4b compares binding isotherms for the interaction between echinomycin and closed or nicked circular PM2 DNA. They cross at an r value of about 0.027, confirming the equivalence binding ratio determined in the sedimentation experiments (Fig. 3a) and corresponding to an unwinding angle 1.89 times

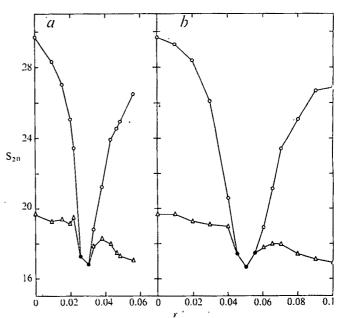

Fig. 3 Effects of (a) echinomycin and (b) ethidium bromide on the sedimentation coefficient of PM2 DNA in SHE buffer. The DNA preparations of contained 80-90% closed circular duplex molecules. Ο, S<sub>20</sub> of closed circles; Δ, that of nicked circles; Φ, weight-average S<sub>20</sub> when the relaxed closed circular molecules cosedimented with the nicked circles. Ultracentrifugation experiments and spectrophotometric measurements of ethidium-DNA binding were as previously described is. Echinomycin-DNA complexes were formed by adding small volumes of antibiotic dissolved in acetone to the DNA in SHE buffer; the acetone was then removed under reduced pressure. The binding ratio (r) was determined from a curve constructed as in the legend to Fig. 2. Sedimentation coefficients are uncorrected values determined directly at 20° C.

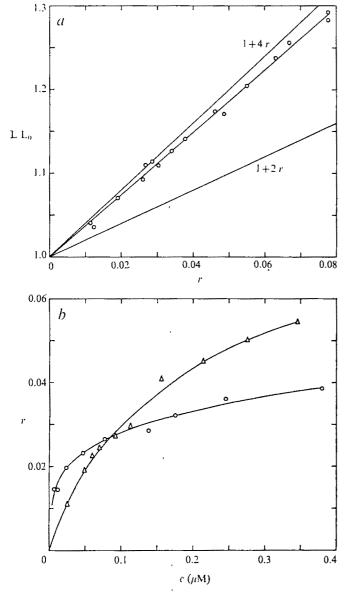

Fig. 4 a, Relative length increase  $L/L_0$  of echinomycin-DNA complexes as a function of the binding ratio.  $L/L_0$  was calculated from viscosity measurements on sonicated rod-like DNA fragments in SHE buffer at  $20^{\circ}$  C using a capillary viscometer as described by Cohen and Eisenberg<sup>16</sup>. The DNA fragments were prepared by sonicating calf thymus DNA to a molecular weight of  $5.4 \times 10^{\circ}$  in an MSE 150 W ultrasonic disintegrator; their intrinsic viscosity in the absence of antibiotic was 3.9 dl g<sup>-1</sup>. Complexes of known binding ratio (r) were prepared as in Fig. 2. The line fitted to the points is a least-squares line, constrained to pass through the origin, of slope  $1+3.73\,r$ . Also shown are theoretical lines corresponding to the lengthening expected for ideal monofunctional intercalation  $(1+2\,r)$  and ideal bifunctional intercalation  $(1+4\,r)$ . b, Binding of echinomycin to closed  $(\bigcirc)$  and nicked  $(\triangle)$  circular PM2 DNA in SHE buffer, determined as described in Fig. 2. The sample of nicked circles was generated by repeated freezing and thawing.

greater than that of ethidium. More important, the enhanced binding to closed circles at ratios below the crossover, and restricted binding above it, are clearly seen. The differential binding to the two forms of DNA at low r is considerably more marked than that reported for ethidium<sup>21</sup>, as expected if the ratio of equilibrium constants for closed circles compared to nicked circles  $(K_I/K_{II})$  is an exponential function of the unwinding angle<sup>17</sup>. Equations (4) and (7) of Davidson<sup>17</sup> predict a value of  $K_I/K_{II} = 5.8$  for echinomycin binding to a typical closed circular DNA at  $r \to 0$ , based on an unwinding angle of 22°. One consequence of this is that any biological property resulting solely from preferential interaction with negatively superhelical

circular DNA would be amplified some 2.23 times with echinomycin  $(K_{\rm I}/K_{\rm II}=5.8)$  in comparison with ethidium  $(K_{\rm I}/K_{\rm II}=2.6)^{17}$ . Furthermore, detailed measurements of the interaction between echinomycin and a range of natural and artificially-closed circular DNAs should enable more accurate estimation of such parameters as the superhelix free energy<sup>21</sup>, in addition to providing a more sensitive probe for the biological relevance of circularity in DNA.

#### Nature of the binding site

The unwinding angle and extension of the helix per bound echinomycin molecule, being double the values observed with classical intercalating drugs, lend strong support to the argument that each chromophore participates in an intercalation process symmetrically related to the binding site of its partner. The two intercalation sites are presumably distinct, because it is practically inconceivable that both chromophores might be accommodated in the potential space between one set of adjacent base-pairs. The symmetry argument would therefore predict that whatever constraints apply to the intercalation site for one chromophore should apply in antiparallel fashion to the site for the other. In the extreme case where each chromophore demanded one specific site out of the ten distinguishable types of potential space<sup>19</sup>, the specificity of binding of the antibiotic as a whole would be phenomenal: one in 40 or one in 100 possible locations along the length of a random sequence would be acceptable, depending on the number of base pairs (1 or > 1)between the intercalated chromophores.

Echinomycin lacks that extreme specificity. Nevertheless, there is some form of subtle specificity in its interaction with DNA. Binding parameters determined for a range of natural DNAs having G+C contents from 29 to 72% yielded values of  $K_{\rm ap}$  from  $4.5\times10^6$  M<sup>-1</sup> to  $4.0\times10^7$  M<sup>-1</sup> with a tendency for the DNAs richer in G+C to bind the antibiotic more tightly. However, two DNAs of identical base composition (*Escherichia* 

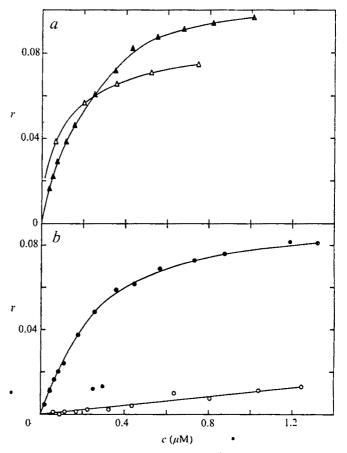

Fig. 5 Interaction between echinomycin and poly(dA) poly(dT) ( $\bigcirc$ ), poly d(A-T); ( $\bigcirc$ ), poly(dG) poly(dC); ( $\triangle$ ) and poly d(G-C); ( $\triangle$ ) in SHE buffer at 20° C, measured as in Fig. 2.

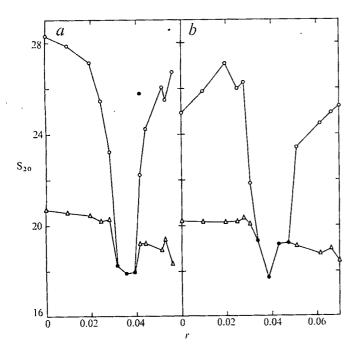

Fig. 6 Effect of echinomycin on the sedimentation coefficient of PM2 DNA at ionic strength 0.1 (a) and 0.5 (b). Symbols and methods as described in the legend to Fig. 3. The buffers were SHE supplemented with NaCl to the required ionic strength. At ionic strength 0.1 equivalence occurs with  $0.036 \pm 0.006$  echinomycin molecules bound per nucleotide; at ionic strength 0.5 the value rises to  $0.041 \pm 0.007$ . In the same buffers equivalence binding ratios for ethidium are  $0.055 \pm 0.005$  and  $0.048 \pm 0.009$ , respectively 25.

coli and Salmonella typhimurium; both 50% G+C) yielded significantly different association constants. Numbers of sites derived from Scatchard plots fell within the range 0.054–0.087 sites per nucleotide, but no correlation with the base composition was apparent.

Striking differences were found when the binding to synthetic DNA polymers was investigated (Fig. 5). Three polymers bound the antibiotic well, albeit with widely different binding constants that is, poly(dG)·poly(dC), poly d(G-C) and poly d(A-T). By contrast, poly(dA) poly(dT) showed barely detectable binding (Fig. 5); neither did poly(dI) poly(dC), poly d(I-C) and poly(rA)·poly(rU), notwithstanding their regular helical secondary structure. The data for the three polymers which showed strong interaction were re-plotted according to the statistical mechanical treatment of Zasedatelev et al.22, from which the number of base pairs occluded per bound echinomycin molecule was calculated to be three for poly d(A-T) and poly d(G-C) but nearer four for poly(dG) poly(dC). The interactions with synthetic polydeoxyribonucleotides will be discussed fully elsewhere, but it should be noted that the capacity of a given polymer to bind echinomycin is not simply correlated with its precise helical form23, nor with the extent to which its helical structure resembles the B-form of natural DNAs. Since coliphage T2 DNA, whose major groove is largely filled by glucosyl substituents, bound the antibiotic well ( $K_{ap} = 1.5 \pm 0.1$  $\times 10^7$  M<sup>-1</sup>; n = 0.054) it is likely that the binding site for the non-intercalated peptide portion of echinomycin lies in the minor groove, as is believed to be true for actinomycin<sup>1,13</sup>. If so, the presence and/or orientation of the 2-amino group of guanine is likely to have important influence on the binding reaction, as is known to be the case with actinomycin<sup>1,13,24</sup> This is clearly implied by the different binding properties of polymers apparent in Fig. 5.

#### Physical characteristics of the binding reaction

The equilibrium constant for binding to native calf thymus DNA at ionic strength 0.01 showed no detectable variation

with temperature between 20 and 40°C. Thus  $\Delta H$  must be close to zero and the binding reaction is driven by a large positive entropy change,  $\div 31$  e.u. per mol of echinomycin bound. These parameters are in exact agreement with those reported for actinomycin binding under almost identical conditions<sup>12</sup>. Unlike actinomycin, however, the solubility of echinomycin in aqueous systems is practically independent of ionic strength and temperature and remains about 5  $\mu$ M. This limited solubility corresponds to a negative entropy change of approximately 25 e.u., suggesting that the major driving force for the binding reaction is the transfer of echinomycin from an aqueous phase into a hydrophobic environment.

When the salt concentration is raised the character of the binding reaction changes. At ionic strength 0.1 the value of  $\Delta S$ falls drastically to near zero and the  $\Delta H$  of binding becomes  $-8.5\pm2.6$  kcalorie mol<sup>-1</sup>. At the same time the equivalence binding ratio for PM2 DNA increases relative to that of ethidium, yielding an apparent unwinding angle of  $18.4\pm3.0^{\circ}$ ,  $1.54\pm0.25$  times that of ethidium (Fig. 6a). In the same solvent, viscometric measurements like those presented in Fig. 4a reveal an extension of the helix corresponding to 1+3.0 r, that is,  $1.50\pm0.05$  times the theoretical extension for a single intercalation event. On raising the ionic strength to 0.5 the trend is continued (Fig. 6b). The unwinding angle becomes  $1.18\pm0.19$ times that of ethidium, and the helix extension falls to  $1.16\pm0.03$ times the value for ideal monofunctional intercalation. The agreement between these totally independent assays of the effect of echinomycin binding on the DNA helix leaves little room for doubt that at ionic strengths 0.01, 0.1 and 0.5 the binding occurs by bifunctional, sesquifunctional, and almost monofunctional intercalation respectively.

#### Structural requirements

The cross-bridged symmetrical octapeptide ring of echinomycin is not merely a convenient handle on which two potentially intercalative chromophores are mounted. In order to investigate the possible role of the chromophores in isolation we studied the interaction of quinoxaline-2-carboxamide (a gift from Dr A. Dell) with DNA. This compound (O2C) produced no detectable effect on the sedimentation of closed circular PM2 DNA at Q2C/nucleotide ratios up to 1:1 in buffer of ionic strength 0.01. Moreover, binding was undetectable by perturbation of ultraviolet absorption spectra or equilibrium dialysis under conditions<sup>25</sup> where interaction characterised by a binding constant as low as 2×103 M<sup>-1</sup> would have been measurable, a factor of 3,000 lower than the binding constant for echinomycin itself. Clearly the tight binding of echinomycin to DNA cannot derive solely from intercalation of the chromophores but must involve interactions with functional substituents elsewhere in the intact molecule, that is, on the peptide ring. Nevertheless, although the chromophores alone do not appear to be able to bind to DNA they undoubtedly play a vital part in dictating the geometry of the antibiotic-DNA complex on which such sequence-specificity as exists must depend. Their intercalation causes the helix to unwind and it is in this distorted configuration that interactions between the peptide portion of the antibiotic and substituents in the DNA must be optimised. Such interactions with the undistorted helix may be unfavourable or indeed impossible.

The role of the bridge across the two antiparallel halves of the peptide ring may be more critical. Echinomycin belongs to a family of chemically related metabolites produced by streptomycetes, known generically as quinoxaline antibiotics<sup>11,26</sup>. This family includes the triostins, which are also antibacterial and antitumour agents<sup>11</sup> capable of powerfully inhibiting RNA synthesis<sup>10</sup>. Triostin A is structurally homologous to echinomycin except that the cross-bridge is formed by N,N'-dimethyl-cystine<sup>26</sup>. Triostin C differs further in that the N-methyl-valine residues are replaced by N,γ-dimethyl-L-alloisoleucine<sup>26</sup>. Both triostins A and C were found to remove and reverse the supercoiling of PM2 DNA but the ratios required to reach equivalence, while still lower than the equivalence ratio for

ethidium, were higher than the equivalence ratio for echinomy-

#### **Implications**

Although drugs which bind to DNA are of paramount importance in several areas of chemotherapy27, not least the treatment of cancer, their capacity to discriminate between DNAs from different sources is minimal if not actually nonexistent19. Few exhibit anything approaching sequence-specificity, the preference of actinomycin for binding to GpC sequences being a possible exception<sup>1,24</sup>. Echinomycin appears to be little better, but at least its capacity for bifunctional reaction heralds the possibility of gaining more genuine sequence specificity. Absolute specificity might be achieved through direct interaction between functional groupings on the basepairs and the drug molecule, or indirectly via recognition of a local conformational peculiarity of the DNA associated with a particular nucleotide sequence23.28. There is evidence that either or both of these phenomena are features of echinomycin-DNA interaction, and we are currently exploring the details in order to develop a precise molecular model for the binding process. Once the exact intermolecular contacts are established, and the importance of the symmetrical structure of the antibiotic is clarified, the way will be open to devise means of enhancing the selectivity of binding. Naturally-occurring analogues with various amino acid substitutions exist, and some analogues with modified chromophores have been synthesised<sup>11</sup>.

A detailed molecular model should also throw light on two outstanding problems concerning the intercalation reaction itself, that is, the origins of the neighbour-exclusion phenomenon (if it exists)19,22,29 and the absolute magnitude of helix-unwinding angles which are currently referred to an assumed value of 12° for ethidium<sup>15,18,21,25</sup>. It may also add to our understanding of how macromolecules such as repressors, transcriptional factors, restriction enzyme's and polymerases recognise specific loci in DNA, and the role of symmetry relationships in such recognition.

We thank many colleagues for helpful advice and discussion, and Dr F. H. C. Crick for a critical evaluation of the manuscript. The work was supported by grants from the Royal Society and the Medical Research Council.

# New observations of the angular diameterredshift relation for radio sources

A. Hewish, A. C. S. Readhead & P. J. Duffett-Smith

Mullard Radio Astronomy Observatory, University of Cambridge, UK

Measurements of the angular sizes of radio source components in the range 0.1"-1.0", using the technique of interplanetary scintillation, reveal an absence of small-diameter sources at the largest redshifts. The cosmological implications of this result are discussed.

It is well known that the angle subtended by a 'standard rigid rod' varies with redshift in a manner which depends upon the assumed cosmological model. In classical world models this angle exhibits a minimum near z=1 which contrasts with the linear decrease of angle obtained for Euclidean geometry. Attempts to use the observed angular diameters of optical galaxies and radio sources to discriminate between different cosmologies have run into various difficulties. The subtleties of applying the test to galaxies have been described by Sandage1 and although progress has been made towards solving some of the problems2 the observations do not yet extend to large enough redshifts for a decisive result to be obtained. Radio

sources are characterised by a large spread of physical sizes which has made them unsatisfactory as rigid rods. When the largest angular sizes of radio sources having steep spectra are plotted against redshift an approximately linear decrease is found to a redshift  $z\sim2$ . Miley has suggested that this apparent Euclidean behaviour might be due to cosmological evolution such that the physical size of a source is smaller at earlier epochs.

Here we use new observations made at a higher angular resolution by the method of interplanetary scintillation.

#### Scintillating sources as standard rods

A radio source will not scintillate strongly unless it contains components which, individually, subtend an angle of less than 2" in any direction and our study is therefore confined to compact features within radio sources, in contrast to their overall angular size.

The observations are taken from a recent survey of scintillating radio sources at 81.5 MHz which has been fully described elsewhere, and we also make use of some additional measurements at 151 MHz. Amongst the 1,500 sources listed in this survey is a complete sample of ~200 3CR sources, a substantial fraction of which have been optically identified and for which the redshifts are therefore known.

By restricting our attention to strongly scintillating sources (those which emit at least 40% of their 81.5 MHz flux from components having an angular size <2") which are also non-variable, we suggest that we obtain a more closely defined range of objects at large redshifts than has been available hitherto for use in the angular diameter versus redshift test. Our reasons are as follows:

(1) An investigation of the nature of this sample has shown that strong scintillators are sources of the highest intrinsic luminosity<sup>5</sup>.

(2) It may be deduced from the spectra of the sources, and by combining scintillation results with high resolution maps made with the Cambridge 5-km telescope, that for sources with steep spectra ( $\alpha > 0.75$ ) the compact features of size <1" are nearly always located in the outer components of typical 'double' radio galaxies. In addition, the ratio (component size/component separation) can be inferred for sources whose components are unresolved by mapping, and it is notable that the values inferred are in fair agreement with those obtained directly from mapping the larger sources. This shows that the source morphology is preserved over a wide range of angular size. The physical sizes of the compact features are typically 2-5 kpc and they are probably similar to the bright "heads" which have been found in Cygnus A (ref. 7); in strong scintillators, however, these regions must emit a substantial fraction of the total flux.

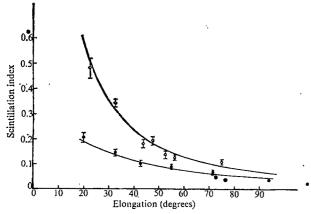

Fig. 1 The observed variation of scintillating flux density ΔS at 151.5 MHz as a function of solar elongation ε, for two typical sources. Also shown are theoretical curves for Gaussian sources of given angular size. (), 3C446 (0.1"); , 3C275 (0.7").

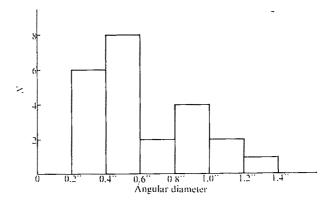

Fig. 2 The distribution of angular diameters for 23 strongly scintillating sources at 81.5 MHz.

(3) In a small number of cases strong scintillators are associated with objects having an overall angular size of less than 1", such as 3C273, 3C279 and 3C446. Sources of this type often exhibit temporal variability at centimetre wavelengths, and have flat radio spectra. These highly compact sources may therefore usually be distinguished, in the absence of angular size data, from the typical double radio sources which have steeper spectra and which are non-variable. Such sources have been excluded from our sample.

#### The observations

Measurements both of angular diameter, and of the fraction of the total flux in components of size <2", can be made with fair accuracy by the method of interplanetary scintillation on sources of high flux density, provided that they can be observed over a wide range of solar elongation ε. The method is illustrated in Fig. 1 which gives two examples of how the r.m.s. scintillating flux density  $\Delta S$ varies with  $\epsilon$ . The angular diameter is obtained by comparing the observations with theoretical curves based on a model of the interplanetary plasma8. The value is not sensitive to the assumed source model9 and the results that we use are based on a circularly symmetrical Gaussian model4. If two or more scintillating components of equal size, spaced by at least 1", are present in a given source (as might be the case for a typical double radio source) the derived angular size is unchanged but the fraction of the total flux in these components is slightly underestimated. The overall reliability of the scintillation technique has been checked by comparison with VLBI methods<sup>10</sup> at the high resolution limit of 0.1"-0.2" and by comparison with maps obtained with the 5-km telescope at the low resolution limit of 1"-2". We find no reason to doubt the validity of results such as those given in Fig. 1.

In the sample of 200 3CR sources there are (classified as A sources in Readhead and Hewish's catalogue') 23 strongly scintillating sources for which curves of a similar quality to those shown in Fig. 1 have been obtained. This sample excludes sources lying within ±20° of the galactic plane where interstellar scattering can give rise to a significant increase in the angular size at 81.5 MHz (ref. 11). The distribution of angular diameters derived from the scintillation curves is shown in Fig. 2.

The rapid decrease in the number of sources having sizes >1" is to be expected because the degree of scintillation falls steeply in this range. A more surprising feature is the peak in the distribution at about 0.4". This value is twice the resolution limit of 0.2" and is unexpected since, a priori, there is no reason to suppose that there will not be a very wide dispersion in the angular sizes of the compact components. If the actual sizes were more or less uniformly scattered over the range below 1.0" then we should expect the numbers to increase rapidly towards the resolution limit because the use of the scintillation technique

introduces a strong selection effect favouring the detection of sources having the smallest angular size.

What other observational selection effects might account for the observed distribution? One possibility might be that the compact components have roughly the same physical size and luminosity, and that they subtend an angle of 0.3"-0.4" when they lie at a distance such that their scintillating flux density falls near the limit for classification as an 'A' source in the catalogue. In that case, however, there should be a correlation between flux density and angular size which is certainly not observed. Thus this possibility cannot explain the observations.

A more important possibility is that we are measuring an apparent size due to angular scattering in the interstellar medium11. Our recent measurements (to be published shortly) of this effect show that an extragalactic point source would have an apparent angular diameter of  $0.17'' \pm 0.3''$  (sin  $b^{11}$ )<sup>-1/2</sup>, which gives a mean value of 0.2''for a random distribution of sources at latitudes  $b^{II} > 20^{\circ}$ . A further check was made by observing a number of sources in the sample at 151 MHz, where the interstellar scattering would be nearly four times smaller. At 151 MHz the angular diameters were typically only 20% smaller, as shown in Fig. 3, in good agreement with the above formula for source broadening at 81.5 MHz. It therefore follows that the values at 81.5 MHz are only slightly modified by interstellar scattering and this is not sufficient to produce a maximum in the distribution near 0.4". We conclude that the distribution of angular diameters is real and cannot be explained by observational selection or other spurious effects.

#### The angular diameter—redshift relation

The angular diameters of the scintillating components are shown as a function of redshift z in Fig. 3, where the limits of the scintillation technique are also indicated. When a given source was observed at 81.5 MHz and 151 MHz both values are shown, and the differences can be ascribed to interstellar scattering as mentioned earlier. It is not surprising, in view of the limitations of the technique, that the measurements show little obvious redshift dependence although there is a tendency for the mean diameter to increase at large z. There is, however, a remarkable deficit of sources having diameters less than about 0.3" in the range  $0.7 \le z \le 1.6$  (denoted by the quadrilateral in Fig. 3).

The sloping lines in Fig. 3 show the expected trend, on the basis of Euclidean geometry, for a population of sources whose physical sizes are independent of redshift. If the population in the range  $0.2 \le z \le 0.5$  is typical then we expect to find about six sources having diameters < 0.2" in the range 0.7 < z < 1.6. Instead of the expected number, clustered near the resolution limit of 0.2", no sources are observed, even though this is the region where the scintillation technique has the greatest detection sensitivity.

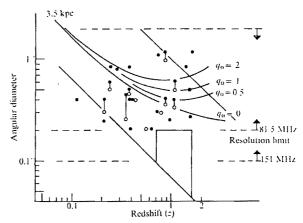

Fig. 3 The angular diameter *versus* redshift relation for strongly scintillating sources. ●, 81.5 MHz; ○, 151 MHz.

A straightforward explanation of these results can be given if a non-Euclidean world model is assumed. The curves in Fig. 3 show the angle subtended by a rigid rod of length 3.5 kpc for different cosmological models assuming  $H = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ . The observations do not seem to fit the curve for a deceleration parameter  $q_0 = 0$ , but are consistent with  $0.5 \le q_0 \le 2.0$ . Any tendency for the linear sizes of scintillating components to vary with epoch will, of course, modify the derived value of  $q_0$ . If  $q_0$  is to be smaller, for example, the linear size must increase with z.

It is clearly desirable to obtain information on a larger sample of sources but it is already evident that the angular sizes of scintillating components in radio sources are hard to explain by Euclidean geometry. Strongly scintillating radio sources appear to provide the best rigid rods that are currently available for cosmological tests.

We thank Dr M. S. Longair and Dr J. E. Baldwin for discussions.

# letters to nature

# X rays predicted from flares of UV Ceti stars

Known UV Ceti flare stars are all located within 20 pc of the Sun, and their distribution seems to be isotropic. They are cool, low-luminosity objects with masses less than  $0.5 M_{\odot}$ . Both optical<sup>1</sup> and radio<sup>2</sup> radiations have been observed during flare events. X rays have also been predicted<sup>3,4</sup>, but no positive

observations have yet been reported. We present here new estimates of X-ray emission, based on the ratio between X-ray and radio flux from solar bursts. It is anticipated that the intensities of the X-ray flares will be more than 10 photons cm<sup>-2</sup> s<sup>-1</sup>; within the range of sensitivities of present satellite detectors (approximately 0.5-0.01 photon cm<sup>-2</sup> s<sup>-1</sup> for a flare duration of 3 min in the energy range 1-10 keV).

Table 1 Predictions and upper limits of X-ray emission during flares of UV Ceti stars

Variability in the types, intensities, and durations of stellar and solar flares makes uncertain both optical/X-ray and radio/ X-ray scaling comparisons. Uncertainties in the optical scaling model of Kahler and Shulman4 arise, however, from two additional sources. First, the optical excess from solar flares is difficult to measure and has been reported for only a few large flares. Second, because of the limited range of optical band widths in which flare stars have been observed, direct comparisons are not possible and bolometric comparisons between stellar and solar flare emissions are dependent on the model used. Predicting X-ray emission using the ratio between solar X-ray radiation and solar radio radiation is less ambiguous because radio signals from solar flares and from flare star bursts have been observed at the same frequencies. Scaling UV Ceti-type emission by using that ratio is justifiable because of the similarities between solar and flare-star bursts and because of the temporal correlation between the X-ray emission and the radio burst signals observed from solar flares<sup>5,6</sup>. Laboratory studies have shown the applicability of such scaling over remarkable ranges of the physical parameters7. Kahn<sup>8</sup>, using both plasma and synchrotron models, has shown that the observed characteristics of flares of UV Ceti stars are consistent with volumes, temperatures, and densities not much different from those suggested for the corresponding models of solar flares. Mullan9 has developed a model of the spots observed on red dwarf flare stars which indicates that the magnetic fields responsible for the star spots have strengths of approximately 20 kgauss. Such fields, approximately 10 times as strong as those observed in sunspots, would provide a factor of 100 in the energy available for release in flares over comparable volumes. The factor of 100 also helps to account, albeit only slightly, for the much greater radio luminosity of flare-star bursts relative to those of the Sun. Lovell<sup>2</sup> has pointed out that many flare-star radio bursts are 104-106 times more intense than the most intense solar radio flares.

Our predictions, based on the ratio between X-ray emission and radio emission from a particular solar flare<sup>10</sup>, are presented in Table 1 together with other predictions and observational upper limits. For comparable energy ranges, the X-ray to radio scaling results yield a factor of 10<sup>4</sup> more X-ray emission than the X-ray to optical scaling suggested by Kahler and Shulman<sup>4</sup>. The solar-flare data we have used does not quote a value for the flux above 10 keV; we have, however, estimated the X-ray emission for energies above 10 keV by scaling the predictions of Kahler and Shulman<sup>4</sup> by the factor of 10<sup>4</sup>. We

obtained an X-ray luminosity of  $3\times10^{28}$  erg s<sup>-1</sup> and an X-ray flux of  $2\times10^{-3}$  photon cm<sup>-2</sup> s<sup>-1</sup> at Earth for a 10 Jy radio burst (210 MHz) of UV Ceti. Although more optimistic than the predictions of Kahler and Shulman<sup>4</sup>, these values lie a factor of  $10^3$  below the predictions of Grindlay<sup>3</sup> and, in this energy range, outside the levels of detectability of present satellites.

Using the requirement that the integrated X-ray flux from all UV Ceti flare stars should not exceed the observed, diffuse X-ray background, and assuming the mean flare-star parameters cited by Edwards<sup>11</sup>, we have calculated upper limits for the X-ray emission of a  $\Delta m_V = 1$  flare of UV Ceti (Table 1). These values are 10-8 times the diffuse luminosity of the Galaxy in each energy range considered. The fluxes based on our scaling predictions do not exceed these limits by more than a factor of 10 in any of the energy ranges. Because of all the uncertainties in the flare-star parameters, especially in their Galactic distribution and density which have been determined only within 20 pc of the Sun, and because of the additional uncertainty in the frequency of occurrence of radio flare bursts, the disagreement is not significant. Depending on the details of their Galactic distribution, the UV Ceti flare stars may, in fact, satisfy the spatial, spectral, and flux characteristics required of unresolved sources of the observed, diffuse X-ray background12.

A search for coincident optical, radio, and X-ray coverage of flare activity in UV Ceti stars is now under way. As indicated by the final entry in Table 1, the MIT OSO-7 X-ray detectors have sufficient sensitivity to refute or to confirm the more optimistic predictions if coincident coverage is obtained. Rates of radio flare bursts above a threshold of 0.2 Jy are comparable to the rates of optical flares above a threshold of approximately  $\Delta m_U = 0.5$  for YZ CMi and AD Leo<sup>13</sup>. A coordinated optical and radio observing programme, using high time-resolution photometric techniques (see ref. 14) has been carried out; and we are examining the OSO-7 data for coincident X-ray observations. Improvement in X-ray sensitivity by a factor of 10 can be obtained using the new, pointed X-ray observatories such as the Netherlands Astronomical Satellite (ANS) or the MIT SAS-C observatory which is scheduled to be launched next June. Prospects for coordinated observing programmes are being investigated.

In the case of solar fast-drift radio bursts (Type III), low energy (~4 keV) X-ray emission is more strongly correlated with the decimetre radio flux than with the metre radio flux, although considerable scatter exists in both populations

(S. Kahler, personal communication and ref. 19). Still better correlation has been found between the higher energy (>20 keV) X-ray flux and the 3 GHz radio flux observed in impulsive solar-flare events20.

Unfortunately, radio observations of UV Ceti flare stars have been almost entirely at radio frequencies about or below 400 MHz. We hope that higher frequency radio observations will be possible and will soon be available.

We thank Dr J. Grindlay for discussing his data before publication; Mr T. Markert, Dr T. Matilsky and Dr A. Solinger for many helpful conversations; and Professors G. Clark, H. Bradt and P. Morrison for encouragement and suggestions. This work was supported in part by the National Aeronautics and Space Administration and the National Science Foundation.

### Positional agreement between 3U1706+32 and the cluster of galaxies A2241

UNIDENTIFIED X-ray sources at high galactic latitudes have been the subject of much discussion (see ref. 1 and refs therein). We call attention here to the existence of a rich Abell cluster of galaxies in the error box of the Uhuru high galactic latitude source 3U1706+32. The X-ray error box is rather large (9.8 square degrees), and the apparent intensity of the source is  $R_x = 4.1 \pm 0.6$  counts s<sup>-1</sup> in Uhuru counts<sup>2</sup>. The cluster, Abell 2241, is located at 16 h 57.8 min  $+32^{\circ}37'(1950)^{3}$ ; it belongs to distance group 3 and has an estimated redshift,  $z \approx 0.07$ (ref. 3). The cluster is of richness group 0 (ref. 3) and has been classified4 as an irregular (I) cluster. The positional agreement between this cluster and 3U1706+32 was not reported in the survey of positional correlations between 3U X-ray sources and Abell clusters of galaxies of distance groups,  $D \leq 3$ , (ref. 5). The cluster A2241 should, therefore, be added as a possible identification to the list<sup>5</sup> of 21 clusters which have been tentatively identified with X-ray sources; no additional Abell cluster of distance group 3 or nearer lies within Uhuru<sup>2</sup> high galactic latitude error boxes.

Although A2241 is located within the error box of 3U1706-32 and is therefore a candidate for identification with the X-ray source, we stress that a much improved X-ray position is required before a certain identification can be made. The X-ray luminosity of the cluster, assuming it to be at a redshift of 0.07, is about  $10^{45}$  erg s<sup>-1</sup> (for  $H_0 = 55$  km s<sup>-1</sup> Mpc<sup>-1</sup>). This luminosity is somewhat higher than the X-ray luminosity range ( $\approx 10^{43}$  to  $\approx 3 \times 10^{44}$  erg s<sup>-1</sup>; see ref. 6) obtained for the other irregular clusters previously identified with X-ray sources, but is comparable with the luminosities of the brightest known regular X-ray clusters.

As is true for most of the other X-ray clusters, radio emission has also been observed from A2241; a double radio source, with a strength of 0.9 Jy at 1.445 MHz, is located in the projected area of the cluster. An elliptical galaxy is located at the radio centroid7. It will be very interesting to learn whether or not the X-ray source is centered on this galaxy.

We consider that A2241 is a possible optical candidate for the high galactic latitude X-ray source 3U1706-32. A better measurement of position is however, required. It is also important to measure the cluster redshift so that, if the identification is correct, the X-ray luminosity can be calculated more accurately.

#### Radio structure of the M87 jet

THE central region of M87 has a complex radio structure. There are at least three components1.2, with diameters  $\approx 0''.0013$ ,  $\approx 0''.01$  and  $\approx 0''.3$ , coincident with the optical nucleus of the galaxy and on either side there are two elongated components, ~25" in extent, the radio counterparts of the jet and counterjet3,4. When observed with a resolution of ≈5", the structure of these outer components is similar and depends little on observing frequency, but at higher resolutions the jet component is seen to possess fine structure which the other lacks5.6. Here I report results of interferometer observations at 408 and 1,666 MHz, with resolving powers  $\approx 0.5^{\circ}$ along the jet, which reveal the position and extent of this fine structure in more detail.

At 408 MHz the interferometer was formed from the Mk 1A (76 m) telescope at Jodrell Bank and a 25-m parabaloid at RRE Defford (baseline 172,700 $\lambda$ ). At 1,666 MHz the Mk II (38 m $\times$ 25 m) telescope and the Mk III (38 m×25 m) telescope were

used (baseline 132,300 $\lambda$ ). The 1,666-MHz interferometer incorporated an improved radio link system (Spencer and Warwick, unpublished) which compensates for changes in the link path delay due to changes in atmospheric conditions. The resulting phase stability enables the position of the radio nucleus to be measured; it is within 0.5" in right ascension and 2" in declination of the optical nucleus, in agreement with earlier radio position measurements.

Strip distributions in right ascension, obtained by direct Fourier inversion of the 1,666 MHz amplitude and phase data,

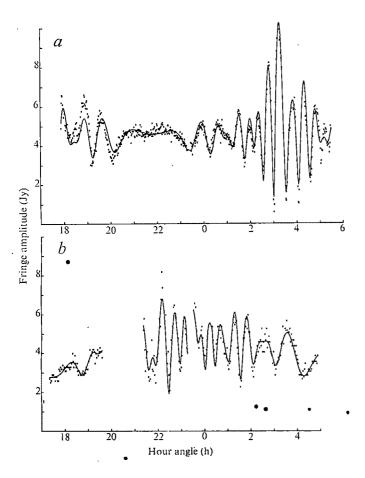

Fig. 1 Variation of fringe visibility with hour angle at a, 1,666 MHz; b, 408 MHz.

show that there are other compact components in the source. The two which are best defined lie on the jet side at between 12" and 15" and at  $\approx$ 18" away from the nucleus. On the other side the amount of emission from compact components is smaller but there may be weak features (  $\lesssim 0.5$  Jy) at  $\approx\!8^{\prime\prime}$  and  $\approx\!13^{\prime\prime}$  away from the nucleus. To investigate the radio structure further the fringe amplitude data were analysed using a model-fitting technique which assumes that the components have Gaussian symmetry. The data are shown in Fig. 1a with the curve which would be given by the adopted model brightness distribution. Because the range of resolutions in the N-S direction is poor, at the declination of M87, the widths of the components are not well defined. In the adopted model all the widths were constrained to be zero but values up to  $\approx 2''$  are also consistent with the data. The values of the optimised parameters of the model are given in Table 1.

The 408-MHz data were only analysed using the model-fitting technique and the adopted values of the parameters are also given in Table 1. The absolute positions of the components cannot be determined at this frequency but from the agreement between the two models it is clear that the 408-MHz observations refer to the same regions of the source as those at 1,666 MHz and that the most intense component is in fact the radio nucleus

The spectra of the individual sources in the nucleus cannot be determined unambiguously. Graham's attempt<sup>3</sup> is incorrect because he recognised only two components and he also included some flux density measurements which are almost certainly contaminated by contributions from compact components in the jet. The present work shows that at least one of the very compact nuclear sources must have a low frequency cut-off near 1 GHz, for the unresolved component in the model has a flux density of 3.5 Jy at 1,666 MHz but less than  $\approx$ 2 Jy at 408 MHz. Further high resolution observations are needed to delineate the spectra more clearly.

The agreement between the well defined components of the 408 and 1,666 MHz models means that the basic structure of the radio jet depends little on observing frequency. The other components in the two models do differ but at both frequencies they indicate that the region between the nucleus and the well defined components in the jet is also a source of radio emission. The brightness distribution of this region is probably complex and synthesis observations are required to reveal its structure unambiguously. Figure 2 shows a photograph of the central region of M87 (ref. 11) and below, plotted on the same scale, contours of the radio emission as described by the model at 1,666 MHz. The striking correspondence between the brightness distributions at optical and radio wavelengths indicates that the structure of the jet is essentially the same over a frequency range of  $\approx 10^6$ :1.

U, Unresolved, dimension arbitrarily put to zero.

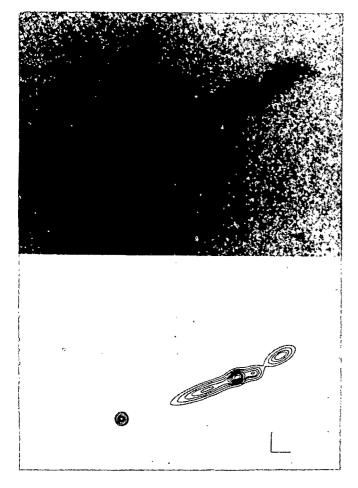

Fig. 2 Comparison of the optical and radio structures of the M87 jet. The photograph is taken from Felten et al. 11. North is at the top and east to the left. Many contours have been omitted from the intense nuclear source for the sake of clarity and the poorly defined component widths have been arbitrarily assigned the value 1". The L in the bottom right hand corner represents 2" in each coordinate. (Photograph reproduced with permission of the Astrophysical Journal.)

A convincing explanation of the physics of the M87 jet is still awaited. The present results show clearly that the electrons responsible for the radio and optical synchrotron emission have very similar spatial distributions, but further high resolution work, especially to locate the variable component<sup>12</sup> and to determine the polarisation structure of the knots at different frequencies, is required before the radio observations can place important constraints on theories of the jet.

I thank R. S. Warwick, R. J. Davis and M. Bentley for the use of computer programs and for discussions.

## 22.2-GHz high emission nebulosities associated with the Carina Nebula central region

MAPS of Carina Nebula, obtained at relatively low frequencies, have shown that most of the radiation arises from a central region and has a simple double structure, separated by about 9.4'. Gardner et al.1 studied Carina Nebula at 5 GHz, the highest frequency so far used, with the Parkes radio telescope and observed a beamwidth of 4'.

Shaver and Goss<sup>2</sup>, used the Molonglo interferometer at 408 MHz (with 2.65' and 2.86' beams in right-ascension and declination, respectively) to study the same region. The two main sources, G287.4-0.6 and G287.6-0.6 (Car I and Car II, respectively1) were suggested as optically-thin thermal regions in the range 408 MHz to 5 GHz, and were assigned electron temperatures of 8,600 K and 8,100 K, respectively.

Using the 13.7 m radio telescope of the Itapetinga Radio Observatory, Atibaia, SP, Brazil, we derived a continuum map at 22.2 GHz from the central region of Carina Nebula, with a beamwidth of 4', and a linearly polarised feed. Because of the large angular extension of the source, we used a loadswitching and on-off technique, with beams 45' apart, for the mapping. Successive positions measured in the source were separated by one beamwidth in declination and/or rightascension. We corrected for tropospheric attenuation and calibrated all measurements against Virgo A, for which we

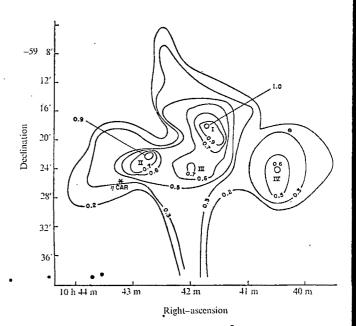

Fig. 1 A radio map from the central region of Carina Nebula obtained on a continuum at 22.2 GHz. Isotherms are normalised in relation to the stronger emission at Car I.

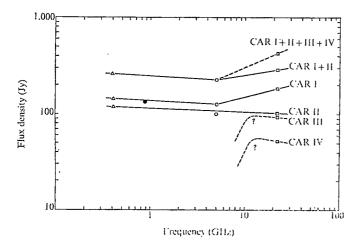

Fig. 2 Integrated spectra for the different components in Carina Nebula. At 22.2 GHz, the flux densities are: 183 Jy for Car I; 104 Jy for Car II; 94 Jy for Car III and 52 Jy for Car IV (all within  $\pm 20\%$ ).  $\triangle$ , ref. 2;  $\bigcirc$ , ref. 3;  $\square$ , our data.

assumed a flux density of 21.5 Jy at 22.2 GHz. The inaccuracies of the intensities measured from Carina Nebula were estimated to be about  $\pm 20\%$ , as the sum of r.m.s. errors, attenuation errors, and source size correction errors. The absolute pointing accuracy of the radio telescope is known to be better than 20", which is negligible compared with the beamwidth at 22.2 GHz.

Figure 1 shows the map at 22.2 GHz, not restored for aerial smoothing. The two main sources identified at 5 GHz1.3 agreed well with those at 22.2 GHz, but the whole region became rather more complex at this higher frequency. Two new structures appeared, one at about  $\alpha_{1950.0} = 10h$  42.0min and  $\sigma_{1950.0} = -59^{\circ}$  24.0', and another at  $\alpha_{1950.0} = 10h$  40.4min and  $\sigma_{1950.0} = -59^{\circ}$  24.0' (corresponding to G287.5–0.7 and G287.2-0.8, respectively) which we have designated Car III and Car IV, respectively.

No enhanced radiation was measured in the direction of ηCar itself, and the radio emission from the central region seemed to follow southwards in a straight bridge centred at about  $\alpha_{\text{1950.0}}=10\text{h}$  42.0min. There is generally no good correspondence between the radio features at 22.2 GHz and the optical features from the nebula.

Figure 2 shows spectra for the central region of the nebula, using data from Gardner and Morimoto3, and Shaver and Goss<sup>2</sup>. We restored the sizes of the sources by simplified techniques<sup>4,5</sup>; to derive integrated fluxes at 22.2 GHz and we assumed a Gaussian form for the antenna beam, and Gaussian distribution of brightness across the sources, with elliptical symmetry. Only Car II seemed to be a normal H II region, optically thin in the range 408 MHz to 22.2 GHz. The other spectra, the integrated ones, and that one for Car I, seem to receive contributions from sources with high emissions, still optically thick at 5 GHz, and probably thin at 22.2 GHz.

The two identified and resolved new sources, Car III and Car IV may be very compact H II regions, with turnoverfrequencies in the range 5 to 22.2 GHz. If we assume that these sources are already optically thin at 22.2 GHz, and the turnover frequency  $f_c$  is about 10 GHz, we can estimate a mean emission after Terzian and Dickey<sup>6</sup>

$$\langle E \rangle = (f_c^2 T_e^{3/2})/k_c \tag{1}$$

where  $T_{\rm e}$  is the electron temperature, and the absorption coefficient  $k_c$  at the turnover frequency (MHz) is

$$k_c = 9.8 \times 10^{-15} \ln(49.5 T_e^{3/2})/F_c$$
 (2)

Assuming that  $T_e \approx 8,600 \,\mathrm{K}$  for these sources, we obtain high mean emissions, of about  $4.3 \times 10^8$  cm<sup>-6</sup> pc.

An accepted distance of Carina Nebula is about 2.7 kpc (ref. 7), from which we estimate an approximate radius for Car IV (better defined in Fig. 1) of about 3.2 pc. The value for the emission is

$$\int_0^R N^2 \, \mathrm{d}R \tag{3}$$

where R is the radius and N the electron density. For a constant distribution of N along R, and along the line of vision, we find an electron density of about  $1.2 \times 10^4$  cm<sup>-3</sup>. The values for  $T_e$ ,  $\langle E \rangle$  and N, estimated for the enhanced sources in the central region of Carina Nebula, correspond to an extreme case of a typical compact H II region as proposed by Mezger<sup>8</sup>. Measurements at a frequency between 5 and 22.2 GHz, and at a frequency above 22.2 GHz, are required to understand better the nature of this interesting nebula.

This research has been partially supported by Brazilian agencies FAPESP, CNPq and CAPES.

## Gyron Field—gravitational analogue of magnetic force

An electrostatic field E in a stationary coordinate system, when referred to a moving coordinate system, can produce both an electric field E\*, and a magnetic field B\*. If v is the uniform velocity of motion, perpendicular to E, then by the usual Lorentz transformation:

$$\mathbf{E}^* = \mathbf{E}/\sqrt{(1-\beta^2)}$$
 and  $\mathbf{B}^* = \mathbf{v} \times \mathbf{E}/c\sqrt{(1-\beta^2)}$ , where  $\beta = \mathbf{v}/c$ .

Consider two stationary point masses,  $m_1$  and  $m_2$ , with respective electric charges  $q_1$  and  $q_2$ . Suppose that the particles are located at 0, r/2, 0 and 0, -r/2, 0 in a system of Cartesian coordinates. If the masses and charges are chosen so that the force of electrostatic repulsion exactly balances that of gravitational attraction, then

$$q_1 q_2 / 4\pi \varepsilon_0 r^2 - G m_1 m_2 / r^2 = 0 \tag{2}$$

where G is the constant of gravitation and  $\varepsilon_0$  is the electrical permittivity of space. Positive signs indicate repulsion and negative signs attraction.

Now suppose that the two particles, while maintaining the same distance apart, are moving with uniform velocity, v, parallel to the x axis. This motion will not disturb the equilibrium of the particles.

From equation (1), the electric force of particle 1 acting on particle 2 becomes

$$\mathbf{E}^* q_2 = q_1 q_2 / 4\pi \epsilon_0 r^2 \sqrt{(1 - \beta^2)}$$
 (3)

Similarly, the magnetic force becomes:

$$q_{2}(\mathbf{v} \times \mathbf{B}^{*})/c = -(q_{2}/c^{2})\mathbf{v} \times (\mathbf{v} \times \mathbf{E})$$

$$= -q_{1}q_{2}\beta^{2}r/4\pi\epsilon_{0}r^{3}\sqrt{(1-\beta^{2})}$$
(4)

The negative sign indicates that this component of force represents attraction.

The electric charges  $q_1$  and  $q_2$  are invariant under a Lorentz transformation, whereas the masses  $m_1$  and  $m_2$  must vary as

$$m_1^* = m_1/\sqrt{(1-\beta^2)}$$
, and so on (5)

Within the framework of special relativity, the ordinary gravitational force, analogous to equation (3) in the moving system, becomes:

$$Gm_1*m_2*/r^2\sqrt{(1-\beta^2)}=Gm_1m_2/r^2(1-\beta^2)^{3/2}$$
 (6)

Hypothetically, linear motion of translation will not disturb the equilibrium of the two point masses. The gravitational force in equation (6) is, however, not functionally compatible with the total electric forces of equations (3) and (4). To achieve the balance of forces a velocity-dependent gravitational force analogous to the magnetic component of equation (4) (which is proportional to  $\beta^2$ ) must be added to equation (6). Thus:

$$[q_1q_2/4\pi\varepsilon_0r^2\sqrt{(1-\beta^2)}](1-\beta^2)-[Gm_1m_2/r^2(1-\beta^2)^{3/2}]$$

$$(1-A\beta^2)=0 \quad (7)$$

where A is a parameter to be determined. From equation (2):

or 
$$A\beta^2 = 1 - (1 - \beta^2)^2;$$
 
$$A = 2 - \beta^2$$
 (8)

This analysis seems to establish the existence of a gravitational force dependent on the relative velocities of moving bodies, as well as on their masses. We suggest that this special force, which must apply to translational motion as well as to rotational motion, be called the 'Gyron Force'.

Lorrain and Corson<sup>1</sup> have mentioned the possibility that such a force exists. They have speculated about "a gravitational equivalent of the magnetic field" but have given no quantitative statement. Moreover, they indicated that this force "could only be attractive", whereas the positive sign of A in equation (7) indicates that the force, as we have derived it, is repulsive. Furthermore, Blokland<sup>2</sup> has concluded, by somewhat obscure reasoning, that the quantity we have designated as A should probably have a value of about 2.

In special relativity, the apparent mass of a body depends on its energy, in terms of the familiar Lorentz transformation. Precise experiments<sup>3</sup> have shown that gravitational and inertial masses are identical to at least 13 significant figures. Apparent mass rather than rest mass must, therefore, be used to define gravitational forces. Thus, our derivation of the gyron field disagrees with that of Sciama4 who used the rest mass instead.

This analysis ignores such phenomena of general relativity as curvature of space. It is, however, clear that the principle must apply in the area common to both general and special relativity. We recognise that a complete derivation must be built on a tensor rather than a vector or scalar theory of gravitation. The result derived here does not depend, however, on any specific theory of gravitation.

We further point out that the existence of forces associated with moving or, especially, rotating masses strongly supports the idea that gravitational waves exist. Such waves must be quadrupole in character. Only the existence of electric charges of opposite sign makes possible the radiation of dipole electromagnetic waves.

We thank Dr Hüseyin Yilmaz of Perception Technology Company for discussion.

# Observation of Comet Kohoutek at 1.4 mm

We made observations of Comet Kohoutek at Kitt Peak with the National Radio Astronomy Observatory (NRAO) 36-foot telescope during two consecutive periods: December 27, 1973-January 2, 1974; and January 6-January 13, 1974.

We used a 1-mm system with our own high performance three-part bolometer<sup>1</sup>: diameter=6.5 mm;  $\tau \simeq 7$  ms; optical NEP at 1 mm=5×10<sup>-14</sup> WHz<sup>-1</sup>. It has a limit of detection of 2 Jy per hour of observation on the radiotelescope with good weather. The system applies a differential modulation at 20 Hz on the sky with two beams each of 1' separated by 2.2'. Scanning of the source and secondary low-frequency modulation to eliminate drifts is carried out by moving the whole telescope.

The bandpass of the system ranges from 1 mm to 3 mm, with a sharp cutoff at 1 mm; the efficiency increases from about 25% at 1.2 mm to 100% at 2 mm. The mean wavelength on a planet of spectral index 2 is thus about 1.6 mm. In the case of cometary dust emission, with a spectral index of pro-

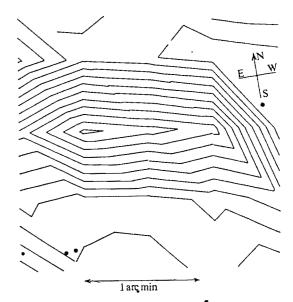

Fig. 1 Comet Kohoutek December 30, 1973; differential isoflux at 1 mm. This map shows interpolated values of points separated 0.5'. It is obtained from preliminary data taken from 1855 to 2000 ur, which are not corrected for field rotation or for atmospheric drift.

bably between 3 and 4, we estimate the mean wavelength to be 1.4 mm.

The field of view of the instrument was of the order of 1' quasicircular, determined from observations of unresolved sources such as planets. The absolute calibration of the flux was made through a straightforward comparison between the observed cometary emission and the flux coming from different planets, observed through the dome during the same day (J.D.G.R. et al., unpublished), corrected for the atmospheric attenuation given by the relationship  $\exp(-a \sec z)$ , where a is a function of time and z is the zenith angle. The position of Venus and Jupiter very close to the comet made this calibration particularly easy.

During the first period, Comet Kohoutek (1973f) was detected clearly on December 30, 1973. On the first evaluation, the cometary flux was of the order of  $100\pm30$  Jy. It was even possible to map the comet's head (Fig. 1). In spite of the poor spatial resolution, it is quite clear that this shape is elongated and orientated in the direction of the Sun, demonstrating that it was the comet, which was under observation.

We next observed the comet on January 12, 1974, when it was much fainter: its flux was then of the order of  $10\pm5$  Jy. This result, compared with the first, shows that to a first approximation the cometary flux at a wavelength of about 1.4 mm seems to decrease as  $r^{-2}$ , where r is the distance from the comet to the Sun.

The total energy available for heating the dust grains is given by:

$$E_1 = \sigma T^4 \sim 1/r^2$$

Therefore, the temperature of the grains should change as  $r^{-1/2}$ . The observed decrease in flux density is much more rapid than anticipated, implying a decrease in the global emissivity of the dust cloud.

This decreasing rate of emissivity may arise from several sources. Two likely possibilities are, first, a change of the dimensions of the emitting head (that is, a probable change in the production rate of dust); second, a change in the emissivity of the dust grains.

Consider the first hypothesis, and suppose that the flux should change as  $\Delta^{-2}r^{-1/2}$ , where  $\Delta$  represents the distance between the comet and Earth. It can then be calculated, to fit the observed variation ( $\Delta^{-2}r^{-2}$ ) to the predicted variation, that the size of the head changed at that wavelength from roughly 1' at the end of December to about 20" around January 12, 1974.

This observation, which represents the first detection at 1.4 mm of a cometary emission, provides new information concerning the rate of dust production and the ejection mechanism of the dust. Comparison of this observed flux with others made at shorter and longer wavelengths, using the blackbody emission law, will probably give the dependence on wavelength of dust grain emissivity, which is directly related to their composition and size.

We wish to thank Elisabeth Rather for programming assistance and the NRAO team for their collaboration at Kitt Peak National Observatory. These observations were sponsored by Centre National de la Recherche Scientifique, Centre National d'Etudes Spatiales, and Institut National d'Astronomie et de Geophysique.

# Microwave search for molecules in Comet Kohoutek

We report here a molecular radio line search in Comet Kohoutek using the 108-116 GHz spectral line receiver on the NRAO 36-foot telescope during January 14-18, 1974. We discuss some of the reasons for the negative results obtained in our search for transitions of methyl cyanide, cyanogen, cyanoacetylene, propynal and formic acid (all good 'parent' molecules for the diatomics and radicals known in the optical spectra of comets).

We particularly searched for the two transitions of methyl cyanide which had been detected by Ulich and Conklin¹ when the comet was 0.8 AU from the Sun before perihelion. As we were observing the comet after perihelion, when it was approximately the same distance from the Sun, the temperature of the cometary material and the excitation conditions should have been comparable. The transitions were detected at the level  $T_A \sim 0.6 \pm 0.1$  K, and our peak-to-peak upper bound for the transitions was  $T_A \sim 0.3$  K.

Initially, we thought that this might indicate a time dependence in the sublimation of 'parent' molecules, perhaps caused by inhomogeneities in the composition of the comet nucleus. We have since learned, however (T. Clark, private communication) that there was a 'time of flight' error in the position ephemeris of the comet that we and many other radioastronomers used. During our observations, the magnitude of the error was ~ 45", as it was during the observations of Ulich and Conklin who used the same ephemeris. For observations with beamwidth 1', a pointing error of this magnitude is clearly very serious. It seems unwarranted therefore to draw many conclusions about the existence of molecules in the comet from these observations.

The National Radio Astronomy Observatory is operated by Associated Universities, Inc., under contract with the National Science Foundation.

#### Solar neutrino puzzle

Davis and his collaborators, using a technique based on the reaction  $^{37}\text{Cl}(v,e^-)^{37}\text{Ar}$ , have been able to set a bound to the flux of neutrinos arriving from the Sun. The latest experimental results¹ correspond to 1 SNU (solar neutrino unit,  $1\times10^{-36}$  neutrino capture per  $^{37}\text{Cl}$  nucleus per second), whereas solar models yield values higher by one order of magnitude². Here I propose an explanation of the discrepancy between theory and experiment on the basis of the assumption that strong interactions between nuclear particles are of gravitational nature³-6.

I shall assume that within the range of nuclear forces, the gravitational constant is 38 orders of magnitude larger. For

distances larger than the Compton wavelength of the proton  $\lambda = 2.1 \times 10^{-14}$  cm, its value decreases exponentially, not to zero, but rather to a value of the gravitational constant as we know it. On the other hand, for distances within 0.21 fermi, the gravitational force would behave as a short range, chargeindependent, non-exchange force, responsible for the strong interactions between nucleons. To remain in agreement with the mass defects of atomic nuclei, the value of the gravitational constant at distances which are small compared to the wavelength of the proton has to be of the order  $G^* = 2.75 \times$ 10<sup>30</sup> c.g.s.

The assumption of a limiting range in the gravitational potential is in itself not as arbitrary as it may seem. The Hubble diagram of quasars7 suggests that the cosmological constant is not zero, which represents by definition a limiting range of the gravitational field. I suggest that there is also a lower boundary. Our physical world is observable between ~ 4,000 Mpc and 1/5 fm.

Should strong interactions between nucleons be gravitational, then all signal carriers with zero rest mass, such as photons and neutrinos, would interact with nucleons like hadrons if their energy is a few GeV. This has been observed for photons in experiments at DESI, Hamburg. An increase of the interaction forces with increasing gravitational mass of the interacting particles could also explain the unexpected increase in the total proton-proton cross section obtained with the CERN intersecting storage rings by the Pisa and Stony Brook teams at energies above 20 GeV.

At  $G^* = 2.75 \times 10^{30}$  c.g.s., the gravitational radius of the proton will become of the order of the Compton wavelength of the proton, leading to the inference that elementary particles behave as black holes. A hypothetical observer within such a black hole can use the Friedmann field equations. Cosmological entities observable within this 'lilliputian' universe have nuclear physical counterparts for an outside observer. For instance, the absolute value of the cosmological constant within the lilliputian universe is identical with the Compton wavelength of the particle. Because of the large value of  $G^*$ , the proton will occupy a hypersphere of radius  $\sim \lambda$  embedded, as is our world, in a four-dimensional continuum. Should the hypersphere of the proton intersect the hypersphere of our world, a proton will appear in our world, as a closed twodimensional space of constant curvature. (Antiprotons intersect our three-dimensional space from the other side.) Assuming that the hyperspheres of particles cannot intersect each other, we arrive at the concept of the hard core, with a range of  $\sim 2\lambda = 0.42 \times 10^{-13}$  cm, which is about the range of the hard core,  $0.53 \times 10^{-13}$  cm, in Levy's potential of nuclear forces. Cosmological, quantum mechanical laws and geometrical rules of two- to four-dimensional spaces supply a sufficient number of equations to yield a quantitative model-like description of fundamental elementary particles<sup>3-5</sup>.

A gravitational interaction between neutrinos and nucleons leads to the inference that even radioactive neutrinos, or neutrinos produced in nuclear reactions occurring in the interiors of stars, can transfer a momentum to nucleons and lose energy while passing through the mass of the star. As long as the transferred energy is small compared to the rest mass energy of the target particle, the momentum transfer can be computed in a classical manner. A neutrino of relativistic mass  $E_{\nu}/c^2$ , passing at a distance a from a nucleus of mass m, will through gravitational interactions transfer a momentum:

$$p_a = aE_v 2G^* m \lambda^{-1} c^{-3} \int_{a}^{\infty} r^{-2} (r^2 - a^2)^{-1/2} (1 + r) \exp(-r) dr$$

where distances are expressed in units of the Compton wavelength of the proton,  $\lambda = 2.1 \times 10^{-14}$  cm. The energy loss of the neutrino will be

$$\Delta E = p_a^2/2m \text{ erg}$$

This energy loss, occurring in an interaction with a nucleus of atomic weight A, can be approximated by

$$\Delta E = 1,630 A E_v^2 \exp(-4.10a) \qquad 0.5 < a < 1.0$$
  
= 390 A E\_v^2 \exp(-2.66a) \quad 1 < a < 5

Assuming that in such elastic interactions a neutrino cannot approach closer to a proton than the hard core range  $a = 2r_0 = 0.625$ , and energy losses at impact parameter a > 5 are negligible, the energy loss suffered by a neutrino of energy  $E_0$  MeV after passing through an absorber of unit (1 g cm<sup>-2</sup>) thickness will be

$$dE/dR = 8.7 \times 10^{-8} E_{y}^{2} \text{ MeV}$$

After traversing an absorber of R g cm<sup>-2</sup> thickness a similar neutrino will emerge with an energy

$$E_{\nu} = E_0/(8.7 \times 10^{-8} R E_0 + 1) \text{ MeV}$$

I note that this result is insensitive to the chemical composition of the absorber. (Inelastic collisions are not considered.)

The average density of the Sun being 1.41 g cm<sup>-3</sup>, and its radius  $5.4 \times 10^{10}$  cm,  $R = 7.6 \times 10^{10}$  g cm<sup>-2</sup>. A neutrino starting with an energy  $E_0$  MeV at the centre of the Sun will leave it with energy  $E = E_0/(6.57 \times 10^3 E_0 + 1)$  MeV. A neutrino from either the <sup>7</sup>Be reaction ( $E_0 = 0.861$  MeV), or the <sup>8</sup>B reaction  $(E_0 = 14.06 \text{ MeV})$  would arrive at the Earth with energy ~150 eV, far below the threshold (0.81 MeV) needed to detect neutrinos in the Homestake mine experiments of Davis.

The energy loss would, however, be much less if the neutrinos were to originate in sunspots, or in stars with densities much below the density of the Sun. One would expect Davis to observe some neutrino flux through the 37Cl(v,e-)37 Ar reaction during sunspot activity, or perhaps during outbursts of nearby supernovae (see ref. 8 for example).

My hypothesis could be tested at an accelerator where neutrinos and antineutrinos of energy 0.5-5 GeV are produced. According to my ideas, some of their energy would be lost in the iron shield used to absorb the muons and other ionising particles. A neutrino of energy 1 GeV, after traversing an iron absorber 20 m thick, would emerge with an energy of 700 MeV, adequate to produce muons when entering a bubble chamber.

# Elemental abundances in interplanetary dust

It is generally believed that the main fraction of dust in the interplanetary medium is generated by the gradual disintegration of short-period comets in the inner Solar System1,2. Analysis of interplanetary dust-grains is, accordingly, a technique for gathering information on the nature of cometary matter. Until now, however, no particle with

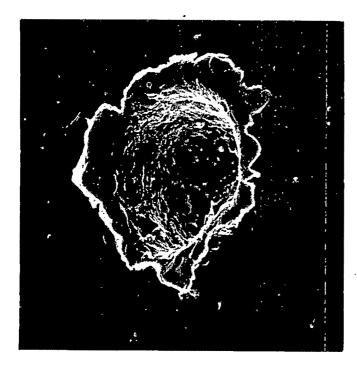

Fig. 1 110 μm diameter micrometeorite crater from Skylab-IV.

an unarguable interplanetary origin has been subjected to detailed chemical analysis.

Here we report the measurement of elemental abundances in two interplanetary dust grains obtained by analysis of meteoroidal residue found inside micrometeoritic craters. The two craters were discovered by scanning optically the 800 cm<sup>2</sup> aluminium surface of the S-228 transuranic cosmicray experiment, exposed to space for 67 d during the Skylab-IV mission. The larger crater is 110 µm wide (measured at the intersection of the pit with the plane of the original surface) and 75  $\mu$ m deep (measured from the pit bottom to the original surface plane). The smaller crater is 35  $\mu$ m wide and 26  $\mu$ m deep. The morphology of both craters is identical to hypervelocity craters produced in laboratory simulations and to craters found on metal grains from lunar soils3. The morphology is diagnostic proof that the craters were produced by genuine interplanetary dust grains impacting at velocities in excess of a few km s<sup>-1</sup>. Laboratory calibrations on aluminium targets (J. F. Vedder, private communication) indicate that the meteoroids had diameters of 30  $\mu$ m and 9  $\mu$ m.

In the scanning electron microscope, residue of the impacting meteoroids can be seen as conspicuous blebs and stringers lining the walls and floors of the craters (Figs 1 and 2). Energy-dispersive X-ray analysis of the 110  $\mu$ m crater in the SEM revealed the presence of Fe, Mg, Si, Ca and Ni in the crater bottom with relative peak heights qualitatively similar to those obtained for chondritic meteorites. For a more quantitative result, both craters were analysed in an ARL-EMX electron microprobe. The craters were tilted with respect to the electron beam and spectrometer to eliminate blocking of the emitted X rays by the steep crater walls. The sizes of the spots analysed on the floors of the large and small craters were 30  $\mu$ m and 3  $\mu$ m respectively. Only a single spectrometer was used for all elements, thereby eliminating the differential geometry problems that would arise from using different spectrometers for different elements. During an analysis run, the orater was kept in a fixed position and the spectrometer was scanned over all of the elements analysed. Before and

after the analysis runs, the spectrometer was scanned over mineral standards for calibration. Repeatability of the peak measurements on the standards was good, and errors arising from spectrometer tuning were small compared with errors caused by the geometry of the crater bottom. Two runs were carried out on each crater. The beam was repositioned and refocused between runs. The aluminium substrate material round the craters was pure; the only indigenous elements detected in it were Ti (130 parts per million), Mg (300 p.p.m.) and Si (4,000 p.p.m.). The only significant substrate interference was by Ti. The Ti upper limit in Fig. 3 represents the substrate Ti concentration.

Because of the complex geometry of the crater it was not possible to use conventional correction procedures on the probe data; the results should accordingly be considered as only semi-quantitative. The geometry affects the absolute X-ray flux received by the spectrometer but does not affect strongly the relative intensities from different elements. The

Fig. 2 Bottom of the 110  $\mu$ m crater showing physical evidence for meteoroid residue. Scale bar=10  $\mu$ m.

measured relative abundance ratios should be fairly accurate. This ratio technique has been applied with considerable success<sup>4,5</sup> to the analysis of other specimens with non-planar geometry.

The small crater was analysed with a point beam at several spots around the crater floor. Iron and sulphur were detected as major elements, and Ni and Mg as trace elements. The small size of the crater makes quantitative analysis difficult but the implied Fe:S ratio is roughly consistent with FeS. The Fe, S and Ni residues indicate that the crater may have been produced by a troilite (or pyrrhotite) meteoroid. Troilite is a common mineral in most meteoritic types. The Fe:Mg ratio was 50:1, so the Mg content is not of major concern.

The results of the two analyses on the large crater are shown in Fig. 3. The two runs agree well with each other, and the agreement with carbonaceous chondrites is within a factor of two for the seven elements quantitatively analysed. Sulphur, a cosmically abundant but volatile element, is not plotted because it was not looked for during that analysis. A sulphur analysis done at a later date, however, showed that sulphur is present in the crater with quite high abundance, qualitatively similar to the abundances of the Fe, Mg, Si group, and compatible with chondritic abundances.

The crater analyses indicate that, for two randomly sampled meteoroids, a 9 µm particle had a composition consistent with troilite and a 30 µm particle contained chondritic abundances. Particles of similar size and chemistry are common in carbonaceous chondrite meteorites and the implication is that the source material for interplanetary dust may be similar to this primitive meteoritic type. Evidence for a similarity to carbonaceous chondrites rather than to other meteorite types comes from the inferred grain sizes within the 30  $\mu$ m particle. As no known mineral contains cosmic abundances, the particle must have been composed of an aggregate of smaller mineral grains. For the composition of the particle to be close to cosmic abundances the constituent grains must have been considerably smaller than 30  $\mu$ m. Few chondritic meteorites outside the carbonaceous group have typical grain sizes as small.

Although these may be the first laboratory analyses of interplanetary grains, there are several other lines of evidence that support similarities between chondritic meteorites and interplanetary material. Studies of the extra-lunar component of lunar soils have demonstrated that the bulk of the micrometeoroid mass hitting the lunar surface has trace element abundances identical to C1 chondrites. In addition

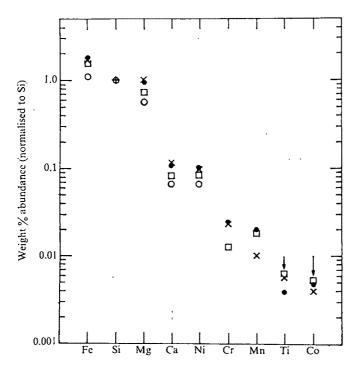

Fig. 3 Elemental abundances in the 110 μm Skylab-IV compared with average carbonaceous chondrite abundances. The open squares and open circles represent different probe runs on the crater. The filled circles and crosses are, respectively, CI and C3 meteorite averages<sup>12</sup>. Ti and Co were not detected in the crater and the upper limits are indicated by arrows.

analyses of meteor spectra1,7 and measurement of mesospheric ion enrichment during meteor showers<sup>8</sup> suggest that the bulk of millmetre-sized particles at 1 AU have abundances close to chondritic values. The apparent similarity between interplanetary material and carbonaceous chondrites should not, however, be construed as evidence that both types of object have a common source. The similarities are probably only a consequence of each type representing primitive, well preserved samples of early solar system materials.

From the microprobe analyses we estimate that some 10% of the two Skylab-IV meteoroids survived as residue. This degree of residue retention is consistent with laboratory simulations9,10 using iron projectiles, but not with studies of micrometeorite craters on lunar rocks11. The difference may arise because the impact of Skylab was on soft metal whereas on lunar rocks it is normally on to silicate materials. The impact conditions are quite different in the two materials, as shown by laboratory observations that for a fixed projectile energy, a hypervelocity crater in metal will have almost ten times the volume of a crater produced in a silicate target10.

The successful detection of residues in the Skylab-IV micrometeoritic craters suggests that if other craters, in appropriate targets, can be recovered from space it may be possible to carry out a statistical evaluation of elemental abundances in debris generated by comets. Primitive meteorites contain large (> 30 µm) inclusions of materials with strongly non-cosmic abundances (such as olivine, magnetite, sulphides, calcium aluminium inclusions and chondrules). Residue analysis of 100 craters or so in the 100-300  $\mu$ m size range would show whether or not these types of particles were also incorporated into the dust-ice matrix of comets. Positive or negative results of such a search would have fundamental implications regarding the interrelationships between comets and meteorite parent

We thank Buford Price and his cosmic ray group at Berkeley for making this project possible.

### Lunar magnetometry and mantle convection

THE hypothesis that the lunar mantle is at present convecting in a manner somewhat similar to that of the Earth is strongly supported by further analysis of lunar magnetometer data. Using the assumption that the electrical conductivity of the lunar interior varies with temperature, as laboratory measurements on rock-forming silicates indicate, I conclude that the Moon has a thermal boundary layer which is no more than 200 km thick and an interior which is relatively isothermal. Such a temperature profile is predicted by the hypothesis of a slowly convecting lunar mantle; it is in serious conflict with the hypothesis that the Moon is statically cooling and has a rigid crust extending to a depth of many hundreds of kilometres.

Early interpretation1 of magnetic transient data from the lunar surface indicated the magnitude of the electrical conductivity of the lunar interior. Sonnett et al.2 argued that these experiments should be interpreted in terms of important compositional differentiation about 200 km below the lunar surface to account for the large electrical conductivity peak there, which the data seemed to imply. Rama Murthy<sup>3</sup> pointed out that such a conductivity profile could result from the presence of an FeS layer at this depth. Kuckes4 concluded that a serious question of uniqueness existed in the Sonett conductivity profile since the data could be fitted equally well with a simple two parameter profile. Subsequent computations by Sonett et al.5 confirmed this conclusion. Hobbs6 applied the Backus-Gilbert test to these two models and argued that the significance of the eight-layer model proposed by Sonett et al. was limited.

Because of the difficulty in assigning a unique conductivity profile to fit the observations, I have chosen to interpret these data in a somewhat different manner, which is much less sensitive to such difficulties. Since the electrical conductivity variation with temperature exhibited by most rock-forming silicates is very strong, direct comparison of temperature profiles with the experimental observations is much more inclined to be unique than are fits of the electrical conductivity profile. Though the exact chemical composition of the lunar interior is not known, the electrical conductivity o can, with reasonable certainty, be assumed to have approximately the exponential variation with temperature T which characterises a semiconductor, namely,  $\sigma = \sigma_0 \exp(-\varepsilon/kT)$  ( $\varepsilon$  an activation energy, k Boltzmann's constant). Measurements of the average lunar density, the lunar moment of inertia and the composition of the lunar material returned to Earth suggest that the composition of most of the lunar interior is relatively uniform. I thus assumed, as a working hypothesis, that the important variation in the lunar electrical conductivity is due to temperature alone and can be written in the exponential form indicated, with the activation energy  $\varepsilon$  and the normalisation constant  $\sigma_0$ fixed though unknown.

To abstract the information needed from the experimental data we continued the practice, initiated by Dyal and Parkin<sup>1</sup>, of comparing in detail the behaviour of transients simultaneously recorded by Explorer 35 and Apollo 12. So that a large amount of data could be considered, individual transients were Fourier analysed in time and the ratio of the dominant amplitude was used to compute experimental values for the field amplification and the lunar transfer function A (ref. 7). The values of A derived by this method conform with those of Sonett et al.<sup>2</sup> in the domain of frequency overlap.

Figure 1 shows rather clearly that only the very outer portion of the Moon can have a significant temperature gradient. A significant temperature gradient extending deeper than about 200 km does not fit the data well.

The effect of varying the temperature gradient below 175 km, that is, below the knee in temperature profile 1, is shown in Fig. 2. The experimental predictions for these three temperature profiles were computed on the basis of the 2.33 eV activation energy reported by Duba *et al.*<sup>8</sup> for olivine. Although all three temperature profiles plotted in Fig. 2 fit the data reasonably

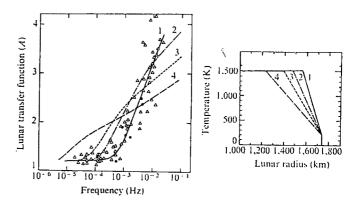

Fig. 1 Experimental values of the lunar transfer function compared to theoretical curves generated by several temperature profiles. The experimental points were obtained by simple Fourier analysis of magnetic transients in the Explorer 35 and Apollo 12 magnetometer records  $\bullet$ , From radial field night-time data;  $\triangle$ , from horizontal field daytime data. The conductivity  $\sigma$  of the outer half of the Moon was assumed to depend on temperature as  $\sigma = \sigma_0 \exp(-\epsilon/kT)$ .  $\epsilon$  was chosen to be 1.5 eV; the general results are not sensitive to the magnitude of  $\epsilon$  if it is greater than about 1 eV. The temperature of 1,500 K for curve 1 was obtained by comparing the magnitude of the conductivity derived to the laboratory measurements of olivine by Duba et al.8. The theoretical curves include a 0.2 contribution to A by the diamagnetism of the solar wind²³.

well, profiles with a temperature difference much greater than 400 K between 1,000 and 1,565 km radius clearly will not. Effectively, the steepness of the experimentally deduced variation of the transfer function A with frequency implies that the electrical conductivity cannot increase by more than an order of magnitude with depth between 1,565 and 1,000 km. Assuming that the significant conductivity dependence in the lunar interior is due to temperature and that the activation energy associated with this temperature dependence is large (as laboratory data indicate) the conclusion that the Moon has a thermal boundary layer which is only a few hundred kilometres or less thick is rather definite.

In the theoretical formulation of the transfer function A, the frequency  $\omega$  and conductivity  $\sigma$  appear only as a product, that is, as ωσ. Thus a change in the value of the conductivity normalisation constant  $\sigma_0$  has the effect of only translating the curves for A horizontally in Figs 1 and 2. The shapes of the theoretical fits shown in Fig. 1 are not particularly sensitive to the value of the activation energy constant ε provided that it lies in the range to make the temperature dependence strong. For rock-forming silicates at the temperatures in question this assumption is fulfilled. The allowable temperature gradient in the interior region shown in Fig. 2 varies inversely with the activation energy  $\varepsilon$ . The vital features, required to obtain the conclusions derived, are that electrical conductivity increases rapidly with temperature, a lunar transfer function A which increases steeply with frequency to a value greater than 3, and the assumption of compositional uniformity.

Leavy and Madden<sup>9</sup> have attempted to fit lunar magnetometer data using the temperature profile proposed by Toksoz *et al.*<sup>10</sup> who considered the thermal history of a hot, cooling Moon. For present-day conditions they obtained a temperature gradient extending to a depth of more than 600 km. Leavy and Madden<sup>9</sup> concluded that consistency with the magnetometer data can only be obtained by assuming that the conductivity of the lunar interior is characterised by a very low activation energy, that is, the conductivity does not change very rapidly with temperature. They point out that this property is difficult to reconcile with the measured properties of the materials generally believed to constitute the lunar interior.

The conclusion that the lunar interior below a depth of about 200 km or less is convecting suggests a striking similarity to terrestrial conditions. The older parts of the Earth's lithosphere are about 100 km thick and have a temperature difference of about 1,300° C across them. About one half of the heat flow observed at most continental sites is derived from the mantle, that is, about  $0.8 \times 10^{-6}$  calorie cm<sup>-2</sup> s<sup>-1</sup> (ref. 11). This value yields an average lithospheric thermal conductivity of about 8×10<sup>-3</sup> calorie cm<sup>-1</sup> °C<sup>-1</sup> and an average specific heat generation for the Earth's interior of  $3.7 \times 10^{-15}$  calorie cm<sup>-3</sup> s<sup>-1</sup>. This value for the thermal conductivity, a 200-km lunar lithosphere, and a temperature difference of 1,200° C across it yields a lunar mantle heat flow of  $0.4 \times 10^{-6}$  calorie cm<sup>-2</sup> s<sup>-1</sup> and an average specific heat generation for the lunar interior of  $7 \times 10^{-15}$  calorie cm<sup>-3</sup> s<sup>-1</sup>. The heat flow computed is about one half that observed12; the specific heating is about double that for the Earth.

It is well known that the Earth's mantle convection induced linear features like mountains, oceanic trenches and island arcs, notably absent on the Moon. I note that the stress on a spherical shell due to loading by a linear feature with a fixed force length and angular width varies approximately as  $r/t^2$ where r is the radius of the shell and t is its thickness. The force length associated with such a feature should vary in proportion to gravity if simple loading by a mountain range is in question, or in proportion to the radius of the body if the viscous drag of the circulating eddy in the lithosphere is involved (assuming constant viscosity). In either case the net stresses trying to break up the lunar crust would be about two orders of magnitude lower than on the Earth.

A great disparity apparently exists between the magnitude of the mantle electrical conductivity of the Moon and the Earth. Because of the complications introduced by the high electrolytic conductivity of the oceans and sediments, the electrical conductivity of the Earth's upper mantle is not well known; it is, however, apparently an order of magnitude greater than that of the Moon<sup>13</sup>. In addition to the very strong temperature effect the electrical conductivity is quite sensitive to composition, particularly changes in the Fe3+ concentration; thus, this disparity is perhaps not too surprising.

Turcotte et al.14 conclude that the critical temperature for mantle convection in the lunar interior is about 1,300° C which closely coincides with the temperature derived. Cassen and Reynolds15 have considered the effect of the temperature dependence on viscosity and have shown that convection can play an important role in the lunar thermal history. The thermal

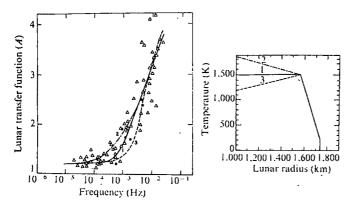

Fig. 2 The variation of the lunar transfer function as the temperature gradient of the lunar interior is varied. From radial field night-time data;  $\triangle$ , from horizontal field daytime data. The electrical conductivity was assumed to vary as  $\sigma = \sigma_z \exp(-\varepsilon/kT)$  with  $\varepsilon = 2.33$  eV. The magnitude of the temperature gradient in the interior region of profiles 2 and 3 is about 6% of that in the thermal boundary layer, that is, outside a radius of 1,560 km.

models of McConnel and Gast<sup>16</sup> which include convection are consistent with our conclusions. Tozer's convective model<sup>17</sup> also predicts a temperature profile in agreement with our analysis; however, the temperature and radioactive heating rate he proposes seem rather low to obtain either convection or the observed value of the observed electrical conductivity.

Without convective transfer of heat most models of the lunar interior lead to the development of a thermal boundary layer too thick to be compatible with my analysis. Toksoz et al.10 have argued for a statically cooling Moon which, at present, has a thermal boundary layer about 600 km thick. Reynolds et al.18 have also shown that an initially cold Moon with a uniform carbonaceous chondritic composition develops a very thick boundary layer.

The computations of Hanks and Anderson<sup>19</sup> show that a present-day thin thermal boundary layer consistent with our conclusion can, however, be generated by the proper combination of surface heat sources and initial temperature conditions at the time of lunar formation. Using a steady state approximation, their work shows that the assumption of complete early differentiation of the radioactive elements to the lunar surface can lead to a wide variety of thermal boundary layer thicknesses depending on the exact balance between initial temperature, absolute magnitude of the radioactive heating rate and the thickness of the heating layer. In any case, the temperatures they discuss are sufficient to make convection likely.

Urey<sup>20</sup> and Gold<sup>21</sup> have long argued for a cold inactive lunar interior. Although exact calculations have not been made, T. Gold (private communication) has argued that deposition of the surface radioactive material somewhat after cold accretion could lead to general consistency with our results. Urey<sup>20</sup> and Gold<sup>21</sup> have also raised concern about the support of the mascons by the lunar lithosphere. While the magnitude of the gravitational anomalies is, in terms of percentage, quite large compared to the terrestrial phenomena, Kaula<sup>22</sup> has argued that isostatic compensation on the Moon is as good or somewhat better than on the Earth and that a 150-km thick lithosphere is sufficient to support the mascons.

I thank Drs Dyal, Parkin and Daily for their help. A discussion with Dr Ness on the role of plasma diamagnetism in the solar wind lead to clarifying this aspect of the work. Helpful discussions with Drs Bilson, Gold and Turcotte and computational help from Messrs Berkowitz and Beckwith are also acknowledged. This research was supported by a NASA grant.

#### Martian terminator waves

I HAVE suggested that the supersonic motion of the Earth's terminator could generate atmospheric waves1, and Raitt and Clark claim to have discovered these waves in the terrestrial thermosphere<sup>2</sup>. The Martian terminator will also be supersonic in a wide band of latitudes in the Martian upper atmosphere and may be expected to produce waves if the region's radiative response occurs on a shorter time scale than the dynamic response.

In Martian low and middle latitudes the terminator moves with a speed,  $V_T$ , of:

$$V_{\rm T} = 240 \cos \phi \, \text{m s}^{-1}$$

where  $\varphi$  is the geographical latitude. If we assume a pure CO<sub>2</sub> atmosphere then the speed of sound, C, is

$$C = 16.2 T^{\frac{1}{2}} \text{ m s}^{-1}$$

where T is the local atmospheric temperature. Supersonic waves may be generated at the equator in regions where T < 220 K, and at latitude 30° if T < 164 K. If we assume that the minimum temperature in the Martian atmosphere is 140 K at the tropopause<sup>3</sup> then these waves can exist for  $|\phi| < 37^{\circ}$ .

In December 1971 Mariner 9 photographed Mars. There were 10 distinct observations of atmospheric wave structure on or near the terminator between latitudes  $+40^{\circ}$  and  $-20^{\circ}$ . Typical wavelengths were 40 km and the lack of any wave structure when photographed through orange filters indicates that the waves occurred in the atmospheric layer above the dust storms that were blowing during the Mariner expedition4. As the dust existed up to 10 km altitude it seems highly reasonable to assume that the terminator waves were generated in the stratosphere (that is, above 15 km) when the stratospheric temperature was sufficiently low. The observed latitudinal extent of the waves agrees well with this hypothesis. There is good reason to believe that the Martian stratosphere is isothermal over a height range of at least 15 km (ref. 3). Provided that the stratospheric temperature is low enough to generate supersonic waves then the resulting disturbances are in phase over that height range. The oscillation produced will, therefore, be evanescent, or very nearly so.

The only waves that will escape destructive interference are those for which the trace of the phase velocity in the direction parallel to the Equator equals the speed of the terminator within the source region of the wave. Only two types of atmospheric oscillations can have supersonic phase velocities. First, very low frequency infrasonic waves which satisfy the dispersion relationship

$$k^{2} = \frac{\omega^{2}}{C^{2}} \frac{\omega^{2} - \omega_{an}^{2}}{\omega^{2} - \omega_{B}^{2}}$$
 (1)

when they are evanescent; and second, the characteristic

surface wave<sup>6</sup>, which is always evanescent, and obeys the relationship

$$\omega^2 = C \omega_{\rm B} k \tag{2}$$

where  $\omega$  and k are the angular frequency of the wave and wavenumber, respectively,  $\omega_B$  is the local Vaisala-Brunt frequency, and  $\omega_{an}$  is the non-isothermal acoustic cutoff frequency, given in terms of the temperature gradient α as<sup>5</sup>

$$\omega_{an}^2 = \frac{\gamma^2 g^2}{4C^2} \div \frac{\gamma g}{2T} \alpha$$

where  $\gamma$  (=1.4) is the ratio of specific heats and g(=3.76 m s<sup>-2</sup>) is gravitational acceleration.

The type of oscillation generating Martian terminator waves can be located by finding  $\alpha$  from equations (1) and (2). For example, the waves at  $+40^{\circ}$  latitude occur when  $V_T = C$ ; thus, the wave parameters are given by  $V_T = C = \omega/(k \cos \theta)$ , where 0 is the solar declination. If we assume  $\theta = 0^{\circ}$ , then  $\alpha =$ 4.26 K km<sup>-1</sup> from equation (1) and 25.6 K km<sup>-1</sup> from equation (2). The first of these is the only realistic value.

It is worth studying Revolution 17 of Mariner 9. Terminator waves were observed at -20° latitude, 20°W longitude. Temperature profiles obtained during this revolution7 indicate that at this latitude the terminator was supersonic from an altitude of 30 km to at least 50 km. The minimum temperature of the tropopause at 38 km is 160 K, and it rises immediately above the tropopause with a gradient of 4 K km<sup>-1</sup>. These experimental results certainly agree very closely with this theory.

There remains, however, one unusual feature of the Martian terminator wave observations. The tilt of the wavefronts corresponds to that expected during the Northern Hemispheric summer, whereas the latitudinal extent of the wave observations seems to indicate that the Northern Hemispheric stratosphere was at a lower temperature than the southern stratosphere.

## Effects of meridional winds on the interpretation of satellite inclination data

DURING the past decade, the analysis of long term changes in inclination of Earth-orbiting satellites has been used to determine characteristics of the zonal wind field in the Earth's upper atmosphere. As reviewed by King-Hele<sup>1</sup>, results of analyses of this type indicate that, on average, the atmosphere between 200 and 350 km rotates faster than the Earth. Average eastward wind speeds of the order of 100 m s<sup>-1</sup> with respect to the Earth's surface are indicated in the altitude region around

The effect of thermospheric winds on satellite inclination is quite small, of the order of 0.1° over a period of several months; as a result long and accurate observations are required to produce useful information. The deduced wind speed applies to a height slightly above perigee and is most heavily weighted by the low latitude wind field, as the effect is strongest at the equator. Since at least several months of data are required for an adequate analysis, the inferred wind is an average over the local times and seasons covered by satellite perigee during that period.

Recent accurate satellite observations using Hewitt cameras have allowed shorter term changes in orbital inclination to be usefully studied. In this way, local time variations of upper atmospheric winds have been determined. Using data of this type for the orbit of Cosmos 316, King-Hele<sup>2</sup> tentatively inferred an 8-h oscillation n the zonal wind field at altitudes of 150–170 km. Here we show that such an interpretation of the data is not unique. In fact, we suggest that short term variations of the inclination may be more realistically explained in terms of meridional wind effects.

The zonal component of the upper atmospheric wind field is not the only component which affects satellite inclination. The meridional wind field can also have a notable effect, especially if its magnitude is as large as that of the zonal wind. King-Hele<sup>3</sup> treated the effect of a meridional wind on satellite orbits and derived the following approximate relationship between the inclination i and the orbital period in days  $T_{1i}$ :

$$\frac{\mathrm{d}i}{\mathrm{d}T_{\mathrm{D}}} = \frac{1}{3\sqrt{F}} \left[ \Lambda \sin i \left\{ (1-4e)\cos^2 \omega - \frac{1}{z}\cos 2\omega \right\} - \left[ -\epsilon(1-\kappa)^{1/2} \left\{ (1-\frac{1}{4}\kappa) \left(1-\frac{1}{2z}\right)\cos \omega - \frac{1}{4}\kappa \cos 3\omega \right\} \right], \quad (1)$$

where  $\sqrt{F=1-\Lambda T_0}$ , cosi;  $\Lambda$ =atmospheric eastward angular velocity in units of the Earth rotation rate; e=orbital eccentricity;  $\omega$ =argument of perigee; z=ae/H; a=semi-major axis of the orbit; H=atmospheric density scale height at perigee;  $\varepsilon$ =atmospheric northward angular velocity in units of Earth rotation rate;  $\kappa$ =sin² $i/(2-\sin^2i)$ .

This relationship is based on a number of reasonable approximations, and is valid for  $z \gtrsim 5$ . As pointed out by King-Hele, the zonal velocity (parameterised by  $\Lambda$ ) leads to a secular change in i as the value of  $\omega$  of the satellite orbit changes. The meridional velocity (parameterised by  $\varepsilon$ ) has no net effect if  $\varepsilon$  is a constant and if the satellite orbit makes a complete cycle in  $\omega$ . The first condition is probably not valid in the thermosphere, however, and the second is not satisfied when short term changes in inclination are studied.

Recent observations of the meridional wind field using the ionospheric radar backscatter technique (see, for example, Evans<sup>4</sup>) indicate that meridional winds can attain speeds of the order of 100 m s<sup>-1</sup> and that there is a strong dependence on local time and season. Theoretical studies of thermospheric dynamics<sup>5</sup> show an additional dependence on latitude. Since perigee latitude and local time and the season vary over the span of orbital data used in inclination analyses, so does the meridional wind ε. Thus, it seems probable that a non-negligible contribution to the change in a satellite's orbital inclination could result from interaction with the meridional wind field whether or not the satellite perigee completes a cycle in ω.

Perhaps even more relevant to the study of short term inclination changes is the observation that meridional wind effects generally will not average out when  $\omega$  goes through only a fraction of a cycle. Although this is immediately evident from equation (1), we have, for purposes of illustration, integrated this equation for a nominal satellite orbit using various combinations of constant values of  $\varepsilon$  and  $\Lambda$ . The orbit used had the following initial values: a=7,682 km, e=0.15,  $i=50^{\circ}$ ,  $\omega=100^{\circ}$ . The initial perigee height for this orbit was 164 km and the parameter z was about 50. The atmospheric density was assumed to vary only with altitude (no latitudinal, seasonal or local time variation) and the vehicle drag parameter  $(C_DA/W)$  was taken to be 0.02 cm<sup>2</sup> g<sup>-1</sup>. The

time history of the orbit over a 5-month period was established using an orbit simulation computer program available at The Aerospace Corporation. It was found that the relevant orbital variables are described with accuracy sufficient for our purposes by the expressions:

$$\omega = 100^{\circ} + 3t$$
  
 $e = 0.15 - 0.00015t$   
 $T_{10} = (111.5 - 0.0286t)/1,440$ 

where t is the time (d) from epoch.

Integration of equation (1) using the above expressions yields the results shown in Fig. 1 for four different combinations of  $\Lambda$  and  $\varepsilon$ :  $\Lambda=1.0$ ,  $\varepsilon=0$  (a);  $\Lambda=1.2$ ,  $\varepsilon=0$  (b);  $\Lambda=1.0$ ,  $\varepsilon=0.2$  (c);  $\Lambda=1.0$ ,  $\varepsilon=0.4$  (d). Curves a and b show the monotonic decrease in inclination that results from purely zonal winds, the larger value of  $\Lambda$  leading to a more rapid decrease in i. The slower variation of i near T=110 min and T=108 min occurs when the satellite perigee goes through apex in the Southern and Northern Hemispheres, respectively. Curves c and d show how meridional winds can affect the time change in inclination. After a complete cycle in  $\omega$  (at T=108 min) the net effect of these constant meridional wind fields is seen to cancel out; but over a time period less (or more) than a com-

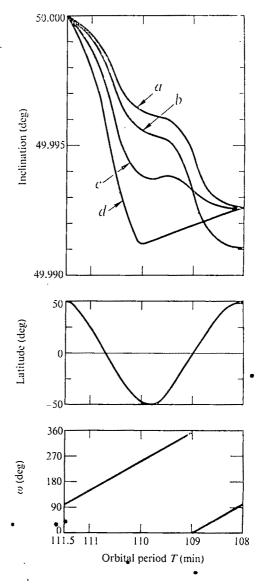

Fig. 1 Orbital inclination, latitude of perigee, and argument of perigee as functions of orbital period. The zonal and meridional wind parameters are:  $\Lambda=1.0$ ,  $\epsilon=0$  (a);  $\Lambda=1.2$ ,  $\epsilon=0$  (b);  $\Lambda=1.0$ ,  $\epsilon=0.2$  (c);  $\Lambda=1.0$ ,  $\epsilon=0.4$  (d).

plete cycle, the change in inclination is substantially affected by the meridional component. The rate of decrease in inclination, attributable to the prevailing zonal component, is modified by the meridional component to be faster or slower depending on whether the satellite motion is against or with the meridional wind. Thus, for example, if the earlier portions (up to T=110min) of curves c or d were used to deduce zonal winds assuming no meridional wind effects, the inferred value of  $\Lambda$  would be larger than actually so. It is seen in curve d that if  $\varepsilon$  is large enough, the inclination can actually increase when the satellite moves in the same direction as the meridional wind. In fact, the inclination data for Cosmos 316 presented by King-Hele<sup>2</sup> show periods during which the inclination increases in a manner quite similar to that depicted in Fig. 1. In an analysis based on only zonal wind considerations, such data would be difficult to fit (as King-Hele acknowledged) and the best fit attainable would in essence disregard such features.

We emphasise that the curves presented here are only illustrative. As pointed out previously, the meridional wind field depends strongly on season, local time and latitude; therefore, in realistic situations the effect of meridional winds would be highly variable depending on the orientation of the satellite orbit in space. The meridional wind effects shown in Fig. 1 are undoubtedly extreme, as we have assumed  $\epsilon$  to be constant and of magnitude comparable to peak values rather than zonally averaged values. Nevertheless, even with smaller values of  $\epsilon$ the effect of meridional winds can easily modify the rate of change in inclination attributable to pure zonal winds. Thus, it seems that inclination data, particularly those encompassing less than a cycle in ω, cannot safely be interpreted on the basis of only zonal wind behaviour.

We thank Dr D. R. Hickman for discussions and Mr W. D. Downs and Mr J.W. Cook for the use of the TRACE orbital determination program. This work was conducted under a US Air Force Space and Missile Systems Organisation (SAMSO) contract.

# Relativistic angular momentum of power circulation

THE purpose of this letter is to show that a special relativistic turning effect results from the angular momentum of the mass circulation connected with closed circuit mechanical or electromagnetic power transmission.

As a result of the relativistic equivalence of energy and mass, the momentum density of a body or a volume section through which power is transmitted is a function of the power flowing through it. In terms of relativity, this follows from the symmetry of the energy-momentum tensor<sup>1</sup>. If P<sub>i</sub> is the power flow per surface unit and c the velocity of light, the relativistic momentum density of the power flow is

$$\mathbf{g} = \mathbf{P}/c^2 \tag{1}$$

The direction of g is the same as that of the power flow, and P can be attributed to any kind of energy transmission, such as mechanical, thermal or electromagnetic. In the latter case, P is identical with the Poynting vector  $\mathbf{P} = \mathbf{E} \times \mathbf{H}$  ( $\mathbf{E} = \text{electric}$ field strength, H = magnetic field strength). For example, the relativistic momentum of a rotating line shaft or of an electric cable of length I transmitting power N is

$$G = NI/c^2 \tag{2}$$

In other words, a body transmitting power can incorporate a momentum without moving in the direction of the momentum.

Of particular interest is the case in which power (that is, mass) circulates on a closed path within a body or a space section. A simple zero-loss power circuit may consist of an electric and a mechanical section: a loss-free electric motor drives a loss-free generator by a line shaft and the electric power delivered by the generator is transmitted back to the electric motor by a loss-free electric cable, so that the power circulates continuously between the electric motor and the generator. Each section of such a power circuit contains a momentum given by equation (2).

A closed mechanical power circuit can be obtained by connecting the ends of a flexible transmission shaft such that it forms a closed ring with mean radius R and that a torque M is conserved in the whole shaft. If the shaft is in rotation about its circular axis with angular velocity  $\omega$ , a power flow  $N=M\omega$  (a mass flow  $m=N/c^2$ ) circulates through it. Equation (2) then yields the angular momentum of this power circulation:

$$J_1 = 2\pi R^2 M\omega/c^2 \tag{3}$$

Inother words, the annular shaft posseses an angular momentum about the axis perpendicular to its plane (a axis) without rotating about this axis. If the shaft rotates freely about the a axis with an angular velocity  $\Omega$ , then the total angular momentum about the a axis is  $J = J_1 + \theta_1 \Omega$ , where  $\theta_1$  is the moment of inertia of the annular shaft about the a axis. Because of the law of conservation of angular momentum, a decrease of  $J_t$ on account of a decreasing power circulation results in a corresponding increase of  $\theta_1\Omega$ . Suppose that  $\omega$  slows down at a rate  $d\omega/dt$  because of internal friction of the flexible shaft. Then the relation between the angular acceleration  $d\Omega/dt$  about the a axis and the rate of decrease of power circulation  $M d\omega/dt$  is

$$d\Omega/dt = -(1/\theta_1) dJ_1/dt_1$$

$$= (-2\pi R^2 M/\theta_1 c^2) d\omega/dt$$
(4)

Electromagnetic power circulation can easily be achieved in a closed superconducting circuit. Figure 1 resembles such a circuit and consists of a toroidal capacitor with a potential difference U between the inner and the outer toroid. Through the

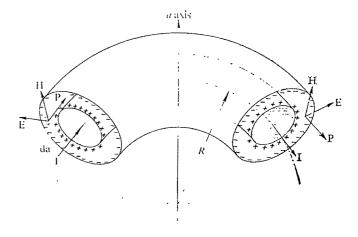

Fig. 1 Illustration of the power circulation in a toroidal capacitor,  $P=E\times H$  - Poynting vector; E= electric field strength; H= magnetic field strength; I= current through the inner superconducting toroid; da - area element of the cross section.

inner superconducting toroid a current I is flowing. At each point of the free space between the toroids there exists a magnetic field  $\mathbf{H}$  and an electric field  $\mathbf{E}$ . The electromagnetic power flow within the toroids is given by

$$N = \int_{1}^{2} \mathbf{P} \, \mathrm{d}\mathbf{a} = UI \tag{5}$$

where P is the Poynting vector and da is an area element of the cross section 1-2 perpendicular to P. Equation (1) yields the momentum density of the electromagnetic field, and the angular momentum of the electromagnetic power circulation about the principal axis of the toroids (a axis) is given by

$$J_2 = (2\pi R^2 U I)/c^2 \tag{6}$$

where R is the mean radius of the toroids.

As the total angular momentum of the toroidal capacitor must be conserved, a change of the electromagnetic power circulation results in a transfer of angular momentum from the electromagnetic field, equation (6), to the conductors. Suppose that the electromagnetic power circulation changes at the rate dN/dt = UdI/dt + IdU/dt, then the corresponding angular acceleration of the toroids about the a axis is

$$\frac{\mathrm{d}\Omega}{\mathrm{d}t} = \frac{2\pi R^2}{\theta_2} \left[ \frac{I \, \mathrm{d}U}{c^2 \, \mathrm{d}t} + \left( \frac{U}{c^2} - \frac{m_e}{e} \right) \frac{\mathrm{d}I}{\mathrm{d}t} \right] \tag{7}$$

with  $e/m_e$  the specific charge of the conduction electrons and  $\theta_2$  the moment of inertia of the toroids about the a axis.

A change of the electromagnetic power circulation can most easily be realised either by a change in the potential difference or by a change in the current intensity. In a practical laboratory experiment, a reduction of the potential difference U can easily be obtained by an internal discharge of the toroids; alternatively the current I can be reduced by heating the superconducting toroid above its critical temperature. Superconducting cables at present under development are designed for power capacities of up to 10 GW (equivalent to mass flow rates of 0.1 mg s<sup>-1</sup>). Under laboratory conditions, much larger power capacities are possible<sup>2,3</sup>, Suppose that a power of 10 GW circulates within a closed circuit cable with R=3 m. Equation (6) yields a relativistic angular momentum of 64 g cm<sup>2</sup> s<sup>-1</sup>, which should be measurable by present means.

The most intense power circulation achieved so far is in high power ring laser (such as the  $CO_2$  laser at Los Alamos<sup>4</sup>). For example, a laser pulse of  $10^4$  J circulating in a path with R=3 m has an angular momentum of  $10^3$  g cm<sup>2</sup> s<sup>-1</sup>.

# Plate tectonic origin for the Cape Fold Belt?

SEVERAL theories based on geological findings have been proposed for the origin of the Cape Fold Belt<sup>1-3</sup>. An understanding of the tectonic conditions leading to the folding is not only of academic importance, but may be valuable in assessing the possibilities of finding oil in the southern Karroo.

Newton<sup>1</sup> argues that the Cape Fold Belt does not resemble a typical 'plate tectonics' orogen in respect of structural style,

sedimentation or igneous and metamorphic activity. A gravityfolding model controlled by the structure of the pre-Cape rocks is proposed. De Swardt et al.2 suggest that the Cape orogeny is of Alpine type, generally ascribed to gravity sliding away from a median zone of excessive uplift, with movement of the cover over a more rigid basement, which is accompanied by folding and thrusting. It is further pointed out that the best explanation for orogenies of Alpine type is that of collision of crustal plates. Sharp<sup>3</sup> implies that diamond-bearing kimberlites are the result of magmatic processes at the deep end of a subducted oceanic plate. The emplacement should occur deep beneath continents and the kimberlite intrusions parallel to fold mountain ranges. South African fields are stated as a specific example of the suggested process. Before the breakup of Gondwanaland, an oceanic plate was underriding the continent; the surface collision produced Cordilleran type mountains, the present Cape Fold ranges. It is shown that the diamond fields occur in bands parallel to the Cape Fold Belt. In spite of the fact that several prominent geophysical anomalies exist in the area, these models were exclusively based on geological arguments. We feel that useful reconstruction of the tectonic history must take the available geophysical evidence into consideration.

An array of three-component magnetometers recorded magnetic variation fields in 1971 over a large part of South Africa<sup>5</sup>. The principal result was the discovery of a linear body of highly-conductive material under the west central part of the Cape Fold Belt (Fig. 1). Although this structure passes south of the

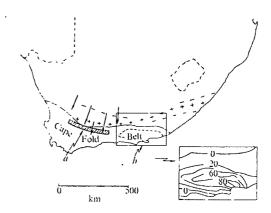

Fig. 1 Magnetic, gravity and conductivity anomalies in the southern point of Africa in relation to the Cape Fold Belt. The maximum (+) and minima (-) of the Beattie magnetic anomalies are indicated. The gravity anomalies are departures from an Airy model of isostatic compensation with crustal thickness 30 km. The inset map is adapted from ref. 6 and the gravity units are in mgal. The arrows represent the negative of the in-phase induction vectors from transfer functions calculated from the estimated normal horizontal components to the anomalous vertical variation field. These vectors that point towards a conductive body are shown for a period of 128 min for the five stations nearest to the anomaly. The approximate position of the conductive Structure is indicated. a, Conductivity anomaly; b, gravity anomaly.

southern corner of the triangular array it could be established that a large highly-conductive body elongated east—west underlies the Cape Fold Belt. Available information indicates that the conductor is in the lower crust or upper mantle. Further work is under way to define the width and axial line of the anomalous zone.

A large negative isostatic gravity anomaly exists in south-eastern. South Africa at the eastern end of the Cape Fold Belt (Fig. 1). It reaches a minimum of -80 mgal of which about 20 mgal can be ascribed to Cretaceous sediments and is elongated along an east-west axis. This anomaly was originally explained as being caused by a relict root or thickening of the crust which had provided Airy-type compensation for a mountain range since eroded away. It was pointed out that a mountain range which would just be supported by the root

F. K. BAHNEMANN

would be 30 km wide and 1.4 km high. As large stresses are necessarily associated with isostatic anomalies of this large magnitude and area, a sequence of failures was predicted by Hales and Gough<sup>6</sup>, leading finally to uplift near the anomaly axis and reduction of the isostatic anomaly and the stresses. There are no large scale isostatic anomalies in the western half of the Cape Fold Belt which could be explained by postulating that the process of uplift is much more advanced there than in the east. Large vertical movement had in fact been observed in the western region<sup>8</sup>.

To explain the conductivity and gravity anomalies, Gough9 suggested that the isostatic anomaly might be the gravitational signature of an east-west trending linear plume in the upper mantle which also produces the conductivity anomaly under the west-central Cape Fold Belt.

The most prominent linear geophysical feature in South Africa is the Beattie Ridge magnetic anomaly10 which lies to the north of and, for most of its 900 km length, parallel to the Cape Fold Belt (Fig. 1). The anomaly consists of a maximum with amplitude ranging from about 100-500 ntesla (total intensity) flanked over large distances by long linear minima. No associated gravity anomaly exists. Deep geo-electrical soundings (J.H. de B., J.S.V. van Z., and F.K.B., unpublished) show that the body causing the anomaly is in the basement beneath the Karroo sediments. Model studies indicate that it is most likely in the middle or lower crust.

This magnetic anomaly cannot be explained in terms of the linear plume hypothesis. On the basis of the available geophysical evidence it is suggested that an oceanic plate underthrust Gondwanaland along one of its margins which coincided approximately with the present southern limit of Africa. Finally a continent-continent collision occurred, producing mountain building which lasted from the Permian to middle Triassic<sup>11</sup>. The most obvious result of this collision is the Cape Fold mountains of South Africa. Overfolding to the north is a prominent feature in these mountains, indicating that the pressure was directed mainly from the south11.

Long linear magnetic anomalies are rarely observed on continents but are typical features in oceanic crust. The long linear Beattie magnetic anomalies may well be caused by the presence of large oceanic slabs thrusted into the original continental edge during or after the formation of a subduction zone near the continental margin<sup>12</sup>.

The roots of collision mountain belts are sialic4 which explains the negative isostatic gravity anomaly associated with the Cape Fold Belt. The absence of an isostatic anomaly in the western half of the fold ranges can still be explained in terms of sub-

Conductivity anomalies in the crust can be related to temperature<sup>13</sup> or composition. Both types of conductivity anomalies are possible in the case of the Cape Fold Belt electromagnetic induction anomaly. If the conductivity anomaly is related to subduction of an oceanic plate and the eventual continental collision, it is most probably caused by a compositional effect. If it is connected to tectonic events surrounding the breakup of Gondwanaland and subsequent tectonic activity, however, there is a strong possibility that the anomaly is associated with anomalously high temperatures and partial melting and that the ridge is in fact a linear region of ascending mantle material as suggested by Gough<sup>9</sup>. This ambiguity as to the cause of the conductivity anomaly can be resolved by a study of the geothermal flux and seismic velocities in the area. This crucial information is not yet available.

Although some features remain unexplained, the geophysical evidence is consistent with the hypothesis that a continentcontinent collision caused the formation of the Cape Fold Belt.

We thank Dr D. I. Gough for suggestions.

#### Thickness of lithosphere deduced from gravity edge effects across the Mendocino Fault

THE evolution of a lithospheric plate, as it migrates away from the accreting boundary (mid-ocean ridge crest), is mostly a result of vertical cooling by conduction. As density is a function of temperature and pressure, the density structure should be a function of the age of the plate and, in order to preserve isostatic equilibrium, the seafloor should subside as the plate cools1. Thus, the variation of heat flow, seafloor depth and the gravity field are different expressions of the same process, progressive cooling, occurring over the whole thickness of the plate. Sclater and Francheteau<sup>2</sup> have verified these properties through an analysis of the variation of heat flow and depth with the age of the plate. Their model assumed that the plate remains a constant thickness and is floating in hydrostatic equilibrium over the asthenosphere. This led to an estimate of 75 km for the thickness of the plate.

Unfortunately, analysis of variation of the gravity field gives little information about structures in isostatic equilibrium with small lateral variations. Beyond the fact that the underlying volumes are of equal weight, the only information it gives comes from the influence of the lateral variation of density structure on the surface gravity field. As the evolution of the plate is slow, with a thermal constant of about 80 Myr (ref. 3), the lateral variations are small and difficult to detect, except perhaps near the accreting plate boundary. Talwani et al.5 have shown, however, that over the Mid-Atlantic Ridge, gravity data combined with crustal seismic refraction data6 imply the existence of a low density upper mantle body of so-called 'anomalous mantle' at shallow depth (less than 40 km) below the surface. Their conclusion is in qualitative agreement with the low densities predicted by the plate tectonics model. But Morgan7 has argued that gravity data alone cannot rule out the existence of a much deeper compensating body. Keen and Tramontini<sup>8</sup> have assumed that this compensation comes from a mass with a uniformly low density contrast, extending to depths of 200 km.

This controversy could be settled<sup>3</sup> with gravity data alone, by studying active or fossil transform fault areas with large offsets, which juxtapose lithospheric plates of different ages (Fig. 1). The resulting large gravity edge effects are quite sensitive to the depths of the compensating masses. We show here that the gravity edge effect produced by the fossil Men-

Fig. 1 Bathymetric map, after Chase et al. 18, showing gravity profiles a, b, and c (see text). Heavy lines, magnetic lineations with ages given in Myr (after Atwater and Menard 11). The Mendocino Fracture Zone juxtaposes sections of lithosphere which are of different ages: across profile a, 0.3 and 31 Myr; b, 3 and 33 Myr; c, 11 and 40 Myr.

docino Fault—a transform fault—can be explained with Sclater and Francheteau's plate model<sup>2</sup>, and that the most probable thickness of the plate is  $75\pm25$  km.

Figure 1 shows the location of three gravity profiles<sup>9,10</sup> across the Mendocino Fracture Zone. Magnetic lineation data<sup>11</sup> show that the lithosphere on each side of the fault differs in age by 30 Myr. Figure 2 shows the free-air gravity anomaly profiles and the corresponding density models proposed<sup>9,10</sup> to explain them. The crustal density structure adopted<sup>9,10</sup> for profiles a and b (Fig. 2) are based on nearby seismic refraction measurements12 using the Nafe and Drake velocity/density relationship<sup>13</sup>. There is no seismic refraction station near profile c(Fig. 1) but Dehlinger et al.9,10 projected results from refraction stations hundreds of kilometres away. In addition, they did not allow for the velocity anisotropy at the Moho interface<sup>14-16</sup>. The density structure they obtained for the mantle is, consequently, rather heterogeneous. In spite of these limitations, their results show the existence, on profiles a and b (Fig. 1), of an edge effect with a 70 mgal low about 100 km wide south of Mendocino. They explain this by invoking a compensating mass which is about 0.2 g cm<sup>-3</sup> lighter in the upper part of the mantle, as originally proposed by Talwani et al.5. The edge effect decreases in amplitude but increases in width on profile c (Fig. 1), as predicted by the plate tectonics hypothesis of thermal evolution of the lithosphere.

We concentrate on profiles a and b (Fig. 1) which have a better crustal seismic refraction control and in which the contrast in thermal structure should be greatest, according to the plate tectonics model. The crustal density structure adopted was given by Dehlinger et al.<sup>9,10</sup>. The density structure of the mantle is deduced from the vertical temperature distribution computed using Sclater and Francheteau's model<sup>2</sup> for a lithospheric plate of corresponding age. We also use their constants. The temperature of the asthenosphere is taken as 1,300° C and the density of mantle material at 0° C as 3.4 g cm<sup>-3</sup>. The only variable parameter is the thickness of the lithosphere, which we choose to vary between 25 and 200 km.

In practice, the density distribution within the lithosphere is computed by assuming that the ocean floor is the top of the lithosphere, but for the part of the lithosphere corresponding to the crust we adopt the density distribution deduced from seismic refraction results. We divide the remaining part of the lithosphere into layers of constant density differing by 0.01 g cm<sup>-3</sup>; the mean density of the layer is obtained from the Sclater and Francheteau model<sup>2</sup>. Corresponding columns on each side of the fracture zone do not have exactly the same weight, because the temperature has been computed for a constant volume lithosphere and because the crust is ignored in the temperature–density model. We restore hydrostatic equilibrium between the two columns by applying to the older a small thickness correction which is proportional to the difference

between the mean computed density of a given layer and the density of the asthenosphere. We also ignore the modification of temperature structure which occurs because of heat flowing by conduction across the fossil transform fault. It can be shown that both simplifications introduce only second order modifica-

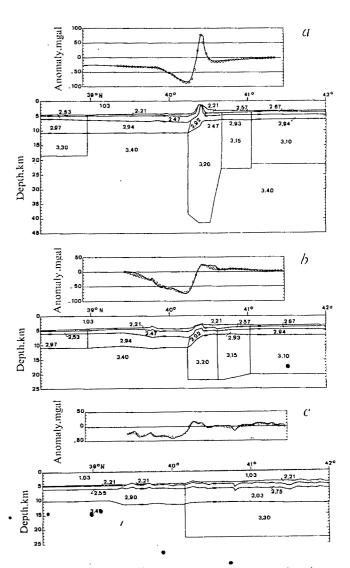

Fig. 2 Gravity profiles (free-air anomalies), and crustal sections along profiles a (along 127° 20′W), b (along 128° 20′W) and c (along 132° 30′W). In crustal sections, depth is shown from sea level, and densities (g cm<sup>-3</sup>) are given. Data from refs 9 and 10.

tions. We felt that the many uncertainties in the data did not warrant testing more elaborate models, such as that proposed by Parker and Oldenburg<sup>17</sup>. Figure 3 shows the density models for profiles a and b.

Figure 3 shows the difference between the observed anomaly and computed gravity anomaly for different models in which the only parameter changed is the thickness of the lithosphere. If the plate tectonics model is correct and if the thickness of lithosphere adopted corresponds to reality, the resulting difference would be zero everywhere. If the thickness is too large then the edge effect is too large and the difference should be positive south of Mendocino and negative north of it. Comparison between computed and observed gravity anomalies shows that the best fits are obtained for a thickness of 75 km (Figs 3 and 4). The data are not good enough to exclude definitely a thickness as large as 100 km or as small as 50 km, but a thickness of 25 km is definitely too small and a thickness of 200 km too large. Thus, models of the type proposed by Morgan<sup>7</sup> or Keen and Tramontini<sup>8</sup> are not compatible with the data.

A thickness of 75 km also fits profile c where the crust is about 10 Myr older than it is near a and b (Fig. 4c). In the absence of nearby seismic refraction stations, we assumed that the crustal structures correspond to those given as a function of age by Goslin  $et\ al.^{18}$ . In addition, the temperature structure may already be affected significantly by the conductive flow of heat through the fracture zone. Consequently, profile c is not as significant as the others.

The lithospheric thickness of 75 km obtained here is identical to that obtained by Sclater and Francheteau<sup>2</sup> on the basis of different types of data (heat flow and depth). This confirms that such a plate tectonics model is successful in accounting for the main physical characteristics of the evolution of a lithospheric plate in its first 40 Myr or so. It also considerably strengthens the choice of physical parameters. The thickness is actually an estimate for a plate 30–40 Myr old. The tempera-

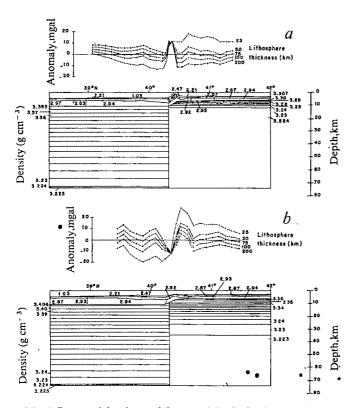

Fig. 3 Proposed density models across Mendocino Fracture Zone along profiles a and b. The thickness of the lithosphere chosen for the models is 75 km. The anomaly curves show the difference between observed and computed gravity anomalies for different lithosphere thicknesses. The density layers have been extended to infinity at both ends to avoid artificial edge effects.

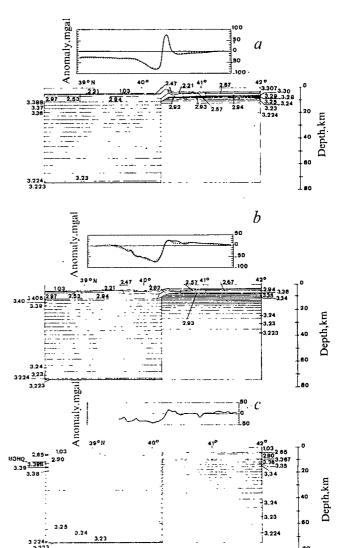

Fig. 4 Proposed density models across Mendocino Fracture Zone along profiles a, b and c and the corresponding observed (solid lines) and computed (dotted lines) gravity anomalies. The thicknesses of the lithosphere chosen for the models is 75 km. For c, the density model of the crust is a function of the age<sup>19</sup> (see text).

ture structure at the accreting plate boundary does not depend on the thickness of the plate; that is controlled by the vertical convection term and not by the conduction term. Thus, this model can be compared with that proposed by Parker and Oldenburg<sup>17</sup> in which the thickness, Z, of the lithosphere changes with age roughly according to the formula:

$$Z(t) = 9.4t^{\frac{1}{2}}$$
 km

where t is time in Myr.

Thus, Z (30-40 Myr)  $\sim$  55 km and the estimate we obtain is in fair agreement with both models within the inherent uncertainties of the data and computations. We feel, however, that more systematic studies, with better seismic refraction and reflection control, across transform faults which juxtapose lithospheric plates of different ages should provide much better constraints to models of lithospheric evolution.

We thank Jean Francheteau and Jason Morgan for discussion and advice.

# Volcanism and glaciation during the past 40 millennia

CLOSE relationships between the timing of volcanic eruption and of glaciation in the past millennia have been noted<sup>1-3</sup> together with the possibility that the three main Neoglacial ice advances were contemporaneous with the three well dated volcanic activity periods in the Southern Andes<sup>3</sup>. Here, I show that glacial advance phases in the Western Northern, Eastern Northern and Southern Hemispheres are mainly synchronous with volcanic activity periods in New Zealand, Japan and southern South America over the past 40,000 yr (the period of reasonably accurate <sup>14</sup>C measurements).

Information on 14C-dated volcanic eruptions and glacial advances is presented in Table 1 together with estimates of their relative magnitudes. All dates used in subsequent discussion are stated in 14C years. The volcanic eruption dates include all those summarised in refs 4, 5 and 6 for New Zealand, ref. 7 for Japan, ref. 1 (after Auer) for southern South America. The glacial advance dates were summarised from a global compilation of 14C-dated advances from many sources. These glacial dates were separated into phases of contiguous advance which were distinct from adjacent phases by at least 200 yr, with the exception of the glacial advance phases during the past two millennia which could be more finely separated. The estimates of magnitude in Table 1 were based on a scale of 1-3 as follows: for the volcanic ash dates, the magnitude of the New Zealand eruptions was determined from the published descriptions<sup>4,6</sup> of the area covered by the

ash showers, with 3 = very widespread, 2 = widespread and fairly widespread and 1 = local. Estimates of the magnitude of Japanese volcanic eruptions were based on the descriptions accompanying the <sup>14</sup>C-dated material<sup>7</sup> as follows: 3 = a major eruption including eruptions which produced a thick pumice layer, 2 = a minor eruption, 1 = a mudflow or (rarely) a lava flow. For the Northern Hemisphere Pleistocene glacial advance phases, a value of 3 indicates a major mid-latitude continental ice advance, a value of 2 a moderate advance and a value of 1 a minor advance. For the subsequent 'Neoglacial' period which occurred after the last readvance of the Wisconsin ice sheet around 7,700–8,300 yr b.p., a value of 2 indicates a major advance of the alpine and polar glaciers and a value of 1 is a minor advance.

The dates for volcanic activity in Table 1 show a tendency for synchronous eruption phases in New Zealand, Japan and southern South America. All eight of the South American volcanic waves are identical with Japanese volcanic phases and six of these are also identical with New Zealand volcanic phases. Of the 18 New Zealand volcanic phases since 33,000 yr b.p., when Japanese dates are first available, 15 are synchronous with Japanese phases, 13 of these by variations of from 0 to less than 300 yr and the other two by variations of 400 and 600 yr. This tendency towards historical synchroneity can also be seen in volcanic eruption dates since 1500 AD (ref. 1) which show that major eruptions occurred in widely separated areas in 1660, 1693, 1694, 1783, 1831, 1846, 1886, 1888 and 1902 AD. Lamb1 has stated that the existence of volcanic synchroneity seems to indicate that stresses build up within the Earth's crust which lead to simultaneous fractures over a wide region.

The dates for glacial advance in Table 1 outline the recognised periods of glacial activity in the late Wisconsin and Holocene. Major continental advances occurred (×1,000 <sup>14</sup>C yr b.p.) around 41.0, 21.0–23.3, 19.4–19.7, 13.7–14.7 and 12.6–13.3, with moderate advances around 35.0–36.9, 30.5–33.5, 17.9–18.6, 16.5–17.2, 10.4–11.0 and 7.7–8.5. Following these large scale glacial advances, there were major Neoglacial advances of alpine and polar glaciers around 4.5–5.3, 2.1–2.9 and 0.04–0.5. The global synchroneity of glacial advance is again evident in the compiled dates in Table 1. The smaller number of Eastern Northern and Southern Hemisphere advance phases could indicate either insufficient knowledge or a genuine lack of glacial activity.

The proximity of the volcanic eruption and glacial advance dates in Table 1 is high. Because of limitations in laboratory technique, no 14C dates are available for Japanese volcanic eruptions before 33,200 yr b.p. and there are no dates before around 17,000 yr b.p. for the southern South American eruption waves. The only earlier information is the New Zealand dates of eruptions around 41,700 $\pm$ 3,500 and 41,000 (67% probability) yr b.p. These dates correspond with the major Gahanna ice advance of the Eire lobe (Fig. 13 of ref. 8). There is no evidence of volcanism during the moderate glacial advance phase around 35,000-37,000 yr b.p. Following this advance phase, all subsequent glacial advances correspond fairly closely with dated volcanic eruptions except the minor advance phase around 15,600-15,700 yr b.p. for which no volcanic dates are available. In two instances there was a lag of 200-300 yr between the volcanic eruption and glacial advance dates: the very minor readvance around 9,200-9,500 yr b.p. which followed a volcanic phase around 9,500-9,800 yr b.p. and the last Wisconsin ice advance around 7,700-8,500 yr b.p. which followed volcanic eruptions around 8,650-8,950 yr b.p. These lags may be climatically significant if they indicate the time necessary for maximum ice advance to occur, once ice build-up has been triggered by volcanic action. Of the eighteen phases of volcanic activity and glacial advance since 17,200 yr b.p., all but four show a lag in ice advance of from 100 to 300 yr following initial volcanic eruption. In three other cases, there is no lag and in one instance, the date of glacial advance precedes volcanic action by 100 yr. Before 17,200 yr b.p. the volcanic and glacial phases are not as well defined; their 14C

accuracy is less and there is no consistent pattern of volcanic activity directly preceding glacial advance.

The relative magnitudes of the glacial and volcanic phases show a fairly close correspondence. The major glacial advance around 41,000 yr b.p. was contemporaneous with fairly to very widespread volcanic eruptions in New Zealand. The next major glacial advances occurred around 21,000-23,300 yr b.p. and around 19,400-19,700 yr b.p. Both these glacial phases were contemporaneous with periods of major volcanic eruptions in Japan, and the 19,400-19,700 yr b.p. ice advances occurred at the same time as a very widespread eruption in New Zealand. The last extensive ice advances of the Wisconsin age occurred during the Cary (Earliest Dryas) around 13,700-14,700 yr b.p. and the Port Huron (Older Dryas) advances around 12,600-13,300 yr b.p. The 13,700-14,700 yr b.p. advance phase occurred during moderate to minor volcanic phases in New Zealand and Japan and a major southern South American volcanic wave. The 12,600-13,300 yr b.p. glacial phase exactly corresponded to a period of moderate to major volcanism in New Zealand and Japan. During the Neoglacial, the three major advance phases of alpine and polar glaciers around 4,590-5,260, 2,100-2,940 and 40-460 yr b.p. were exactly contemporaneous with the three major post-Wisconsin volcanic activity phases around 4,700-5,450, 2,150-2,850 and 50-470 yr b.p. in New Zealand, Japan and southern South America as originally noted for the South American data<sup>3</sup>.

The temporal synchroneity of the glacial advance and volcanic activity phases shown in Table 1 may be more than coincidental, if the strong connection between volcanic ash and subsequent glacial advance demonstrated3 since 1500 AD reflects a valid causal relationship. The fact that both the late Wisconsin and Neoglacial ice advances are contemporaneous with major phases of volcanic activity suggests a volcanic trigger for glacial advance. Once this triggering occurs, the subsequent magnitude of glacial advance may depend partly on the magnitude of the volcanic activity and perhaps partly on autocatalytic mechanisms similar to those proposed by Adam9 or Segota10, with the extent of glaciation related to position in the autocatalytic cycle. There is also a possibility that recurrent intervals of diminished solar activity may have created periods of cooler climate<sup>2</sup> which, if coincident with a volcanic activity phase, would have increased the effectiveness of the volcanic ash in stimulating glacial advance.

The close correspondence between periods of volcanic activity and glacial advance since 41,000 yr b.p., shown in Table 1 may have extended throughout the Quaternary. Fuchs and Paterson<sup>11</sup> have reported a similarity between the main epochs of Quaternary glaciation and volcanic activity in a number of regions of low latitude. Hamilton and Seliga<sup>12</sup> found that during the past 100 millennia the temperatures over the Antarctic and Greenland ice sheets were inversely proportional to the amount of volcanic dust which had fallen on these ice sheets.

#### New dense phases of geophysical significance

THE major increases in density occurring at depths of 400-1,000 km in the Earth's mantle require the formation of phases in which silicon is six-coordinate. Such coordination has been demonstrated in stishovite (SiO2 of rutile type1), in the hollandite form of feldspar compositions2, in the garnet form of (Mg,Fe)SiO<sub>3</sub><sup>3</sup>, in garnet-type MnSiO<sub>3</sub><sup>4</sup>, in perovskite-type CaSiO<sub>3</sub><sup>3</sup> and in SiP<sub>2</sub>O<sub>7</sub><sup>5</sup>—but examples are still few. For the two compositional types believed to provide the bulk of the mantle,  $ASiO_3$  and  $A_2SiO_4$  where A is Mg or Fe, high pressure phase transformations of numerous model compounds such as MnGeO<sub>3</sub>, CaGeO<sub>3</sub>6, Mn<sub>2</sub>GeO<sub>4</sub>, and Ca<sub>2</sub>GeO<sub>4</sub>7 have demonstrated the possibility of high pressure ilmenite, perovskite, strontium plumbate and potassium nickel fluoride forms, respectively, as ultimate high pressure silicate phases; and disproportionation into simple oxides has also been discovered8,9. In the absence of directly observed silicate transformations it is important to delineate the systematic crystal chemistry of each of these structural classes, particularly for those members containing ions closest in size to Fe, Mg and Si, and to obtain further examples of six-coordinate silicon in a range of compounds.

Since the ionic radius of  $Sc^{3+}$  (0.73 Å) is similar to those of  $Mg^{2+}$  and  $Fe^{2+}$  (0.72 and 0.77 Å) while that of  $Al^{3+}$  (0.54 Å) is comparable, with that for octahedral  $Si^{4+}$  (0.40 Å), the composition  $ScAlO_3$  seemed a suitable analogue for perovskite-type (Mg,Fe) $SiO_3$ , although it does not form a compound under normal conditions. We found that an equimolar mixture of amorphous  $Sc_2O_3$  and  $Al_2O_3$  (formed by heating the coprecipitated hydroxides in a vacuum), when reacted in an opposed anvil apparatus at 1,000° C and 120 kbar, gave an orthorhombic perovskite with a=4.933, b=5.226 and c=7.193 Å, isostructural with the rare earth orthoferrites<sup>10</sup>.

Thus an ion of the size of  $Mg^{2+}$  can be accommodated in the A site of the perovskite lattice, while the high pressure behaviour of compositions  $CaTiO_3$ – $CaSiO_3$ <sup>3</sup> have demonstrated that  $Si^{4+}$  can occupy the octahedral B site. It seems highly plausible that  $MgSiO_3$  perovskite will become stable at very high pressures.

Structural refinement based on powder diffraction data showed Sc to be eight-coordinate with an average bond length of 2.25 Å, similar to that for Mg<sup>2+</sup> in pyrope garnet<sup>11</sup>. The Al—O<sub>6</sub> octahedron exhibits normal Al—O bond lengths. We would similarly expect that Si—O<sub>6</sub> octahedra in a perovskite form of MgSiO<sub>3</sub> would conform to the bond lengths found

<sup>\*90%</sup> confidence levels.

in rutile form SiO<sub>2</sub>, or in the pyrochlore silicates discussed below.

Consideration of the volume of the ideal perovskite cell as the product of its unit cell edges has led to a molar volume scheme in which the unit cell volumes of real perovskites are expressed as

$$V = C (A - O)^{x} (B - O)^{3-x}$$

where (A-O) and (B-O) are bond lengths taken from compounds of C-rare earth, rocksalt, rutile or corundum type. For more than 20 known A2+B4+O3 perovskites, including high pressure phases, unit cell volumes can be fitted within  $\pm 0.45\%$  by the values C = 24.29, x = 0.970, and extrapolation with considerable confidence made to the volumes of the geophysically important compositions MgSiO<sub>3</sub>, FeSiO<sub>3</sub> and CaSiO<sub>3</sub> and to solid solutions (Mg,Fe)SiO<sub>3</sub> (Table 1). A<sup>3+</sup>B<sup>3+</sup>O<sub>3</sub> perovskite volumes can similarly be fitted using C = 23.51, x = 1.159. The densities predicted for MgSiO<sub>3</sub> and (Mg<sub>0.86</sub>Fe<sub>0.14</sub>)SiO<sub>3</sub> are very close to those inferred for the zero-pressure densities of the shocked high pressure forms of these phases<sup>12</sup>. Table 1 shows that (Mg,Fe)SiO<sub>3</sub> perovskites would be 4-5% denser than isochemical oxide mixtures (Mg,Fe)O+SiO<sub>2</sub> (stishovite). Consequently, even if disproportionation of MgSiO<sub>3</sub>-FeSiO<sub>3</sub> composition occurs in the transition zone8,9, the oxides are likely to recombine in the deep mantle to form the denser perovskite phase.

In searching for additional examples of six-coordinate silicon we have found that thortveitite, Sc<sub>2</sub>Si<sub>2</sub>O<sub>7</sub>, and its indium isotype, In<sub>2</sub>Si<sub>2</sub>O<sub>7</sub>, are transformed at 1,000° C, 120 kbar to cubic pyrochlore type, with  $a_0 = 9.287$  and 9.143 Å, respectively. In this  $A_2B_2O_7$  structure, A ions are eight-coordinate and B ions six-coordinate. As the only variable atom position in the pyrochlore structure is O(2), at (1/8, 1/8, x), and all six Si—O bonds are equal, the silicate pyrochlores are particularly suited to structural refinement from powder data. The results are summarised in Table 2. An Si—O bond length in Sc<sub>2</sub>Si<sub>2</sub>O<sub>7</sub> of 1.766±0.007 Å was obtained. The Si—O bond length in  $In_2Si_2O_7$  is 1.794  $\pm 0.008$  Å, a value different from that in the scandium compound. This effect may be due to the very marginal ionic radii fit of In and Si in the pyrochlore structure, although similar variations are observed in the polytypes of SiP<sub>2</sub>O<sub>7</sub><sup>5</sup>. The average Si—O bond length for the two silicate pyrochlores (1.780±0.014 Å) is, however, very close to that for rutile-type  $SiO_2$  (1.775±0.006 Å)<sup>13</sup> and a value of 1.78  $\pm 0.01$  Å would seem to define the values expected in high pressure mantle minerals.

Strong evidence has now been obtained (L. Liu, personal communication), by using laser heating of samples pressed between diamond anvils, for the existence of a perovskite phase close to MgSiO<sub>3</sub> in composition and with a unit cell volume almost identical to that predicted in Table 1.

### Tar pollution of Sierra Leone beaches

THE widespread occurrence of pelagic tar and plastic wastes in parts of the Pacific and Atlantic oceans has been described previously. Extensive and considerable fouling of the sandy beaches of Sierra Leone by tar lumps has now been observed at Lumley, Sussex, No. 2, Toke and Mamah villages (Fig. 1) during the past 14 months (June, 1973 to July, 1974). Large quantities of soft, brownish-black lumps (up to 7-8 cm diameter) have been repeatedly washed ashore along the entire stretch (about 6 km) of Lumley beach. This reaches a maximum during June to August, probably because of onshore south-western Monsoonal winds and the increased eastward flow of the Guinea Current during May to October<sup>2</sup>. On August 4, 1974, tar lumps were also observed 1-2 km up the No. 2 River estuary; and during Easter, 1974, a 4-5 km stretch of the sandy beach at Shenge village (7° 56'N 12° 56'W) at the southern tip of Yawri Bay, was also littered with the pollutant. Observations have not been made south of Shenge and north of Freetown (8° 29'N 13° 4'W) but the extent of current pollution tends to suggest that the whole Sierra Leone coastline, and perhaps those of the flanking countries as well, may be subject to frequent tar pollution, probably originating from the heavy, offshore traffic of tankers and ships.

At Lumley beach during ebb tide, tar lumps and other debris are deposited on the sand in a series of crescentshaped aggregations by the receding waves. I have observed ghost crabs (Ocypode spp.) moving along these aggregations and from one crescent to another at different levels of the beach, probably as scavengers. Some workers1 have already noted that the lumps are inhabited by a variety of marine organisms and I have seen several lumps (3-4 cm diameter) bearing colonies of 3-5 small goose barnacles. At succes-

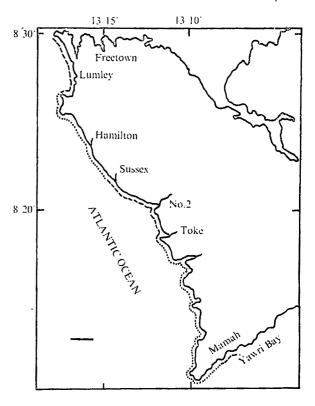

Fig. 1 Western area peninsula of Sierra Leone, showing the sites with tar polluted shores (dashed line) and the probable extent (dotted line) of the peninsular coastline affected by the pollutant. Scale bar represents 2.5 km.

sive spring tides, the lumps and the debris are swept by waves to the supralittoral fringe, leaving the littoral region momentarily clean until the next fresh influx of the pollutant. At the supralittoral fringe, tar lumps are lodged in the soft, dry sand and between the grass roots; here they harden, baked by the hot sun of the dry season (November to April). Fresh tar lumps easily stick to the feet, being effectively removed only by kerosene or local palm oil.

# In situ methylation of mercury in estuarine sediment

THE methylation of mercury compounds in sediments, believed to be a biological process, has been shown in a number of laboratory experiments1-5. Background levels of methylmercury (CH<sub>2</sub>Hg) have been reported for estuarine sediments from the Mississippi Delta, Mobile Bay and the Florida Everglades. We now report that sediment in San Francisco Bay contained background levels of methylmercury and methylated mercuric chloride (HgCl<sub>2</sub>) in situ.

Methylmercury was analysed using a Varian 1200 chromatograph equipped with an electron capture detector. The column (length 182.8 cm, internal diameter 0.318 cm) contained 5% 'butanidiol succinate' on 'chromosorb W' 80-100 mesh and was maintained at 160° C. The presence of methylmercury was verified by comparing total mercury (Hg) with the amount of methylmercury in the extracts. This verification was carried out on an isotope shift Zeeman effect atomic absorption (IZAA) spectrometer7. Total mercury in sediment samples was also measured on the IZAA spectrometer. Methylmercury was extracted using a modification of the Westöö method8. Ten grams (wet weight) of sediment were placed in a 250 ml glass centrifuge bottle to which 25 ml H<sub>2</sub>O, 10 ml concentrated HCl, 10 g NaCl, 2 ml 5% HgCl<sub>2</sub> (w/v) and 40 ml of benzene were added. The samples were shaken for 15 min and then centrifuged at 490 relative centrifugal force for 8 min.

Thirty millilitres of the benzene fraction were removed and placed in a 60 ml separating funnel. A 1% cysteine acetate solution (6 ml) was added and the samples shaken for 2 min. The cysteine acetate solution was withdrawn, measured and placed in a 30 ml separating funnel to which 3.6 ml 6 N HCl and 4 ml benzene were added. This solution was shaken for 2 min and allowed to stand for 10 min, the benzene was then removed and

stored for analysis. The extraction efficiency was 92.9% and the limit of detection was approximately 0.01 ng g<sup>-1</sup>. Sediment was analysed for volatile solids9 and particle size distribution10.

To study methylation of HgCl<sub>2</sub> in the natural environment, wire mesh cylinders were embedded in the sediment of an intertidal zone of central San Francisco Bay. Sediment from the inside of each of the four cylinders was removed, separated and weighed; HgCl2, dissolved in deionised water, was added to make 10 and 100 p.p.m. concentrations of Hg (wet weight) in each of two sediment zones (shallow and deep). Mercury was added to only one zone of each cylinder. The shallow zone was formed by replacing the appropriate mercury-sediment mixture only in the upper 1.27 cm of the cylinder. The deep zone was formed by replacing the bottom 6.35 cm with the mercurysediment mixture and covering the upper zone with the original 1.27 cm of sediment. Duplicate 10 g sediment samples were taken from the cylinder on days 0, 18, and 28 of the experiment. Control samples were taken from areas adjacent to the experimental site.

The sediment which represented shallow and deep samples had an average volatile solids value of 2.5%. The particle size distribution was 55.0% medium and fine grained sand, 35.3% silt and 10.7% clay.

Methylation occurred in excess of background levels, being greatest in the deep zones. Background levels of methylmercury fluctuated over the study period from 0.01 to 0.14 p.p.b. CH<sub>3</sub>Hg. We found that the fluctuations in total mercury as well as methylmercury concentration in San Francisco Bay sediment were a common occurrence throughout the year. Total mercury measurements during the study show a continuous decrease from the original values of 10 or 100 p.p.m. Hg. By the 28th day the initial 10 and 100 p.p.m. of Hg was reduced to 0.2 and 0.1 p.p.m., respectively, in the shallow sediment and 2.8 and 10.5 p.p.m., respectively, in the deep sediment. The in situ sediment had a total Hg content of 0.19 p.p.m.

Methylmercury was therefore produced in situ by San Francisco Bay sediments and natural background methylmercury was also observed. The amount of CH<sub>3</sub>Hg produced in situ was far below that found under laboratory conditions1-3 but significantly above background levels. The decrease in the amount of methylmercury found in most cases on day 28 could reflect a decrease in methylation resulting from a decrease in the amount of total mercury present by the diffusion of both methylmercury and inorganic mercury out of the experiment sediments. The loss of mercury was possibly aided by the degradation of methylmercury to its inorganic form, a phenomenon which has been shown to occur under laboratory conditions<sup>3,11-13</sup>.

Andren and Harriss<sup>6</sup> found that background levels of CH<sub>3</sub>Hg decreased with sediment depth (sediment taken from Mobile Bay). This study has shown that at least in the initial phases of methylation, sediment at 6 cm produced more CH<sub>3</sub>Hg than sediment at the surface.

The higher values of CH<sub>3</sub>Hg in deep sediments could indicate: that more methylation occurs under anaerobic conditions; there is a greater loss of CH<sub>3</sub>Hg from the shallower sediments; or there is a greater rate of CH<sub>3</sub>Hg degradation in the shallow

#### Upper mesospheric wind structure in Antarctica

UNDER a joint Indo-Soviet agreement I was the first Indian scientist to winter in Antarctica during the 17th Soviet Antarctic Expedition, 1971-73. In particular, I participated in the meteorological rocket soundings of the upper atmosphere carried out at Molodezhnaya, a station located at 67° 40'S, 45° 51'E at a height of 42 m above mean sealevel in Enderby Land, East Antarctica (Fig. 1).

In 1972 the mean annual temperature observed at the station was  $-10.5^{\circ}$  C varying from a lowest minimum of -35.8° C to a highest maximum of 7.0° C. South-east winds prevailed at the surface with frequent gusts of 21-41 m s<sup>-1</sup>. Annual mean relative humidity was 65% and the annual mean precipitation observed was 0.14 cm.

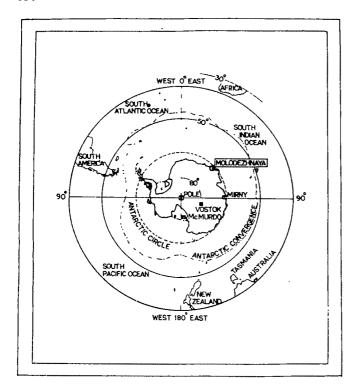

Fig. 1 Map of Antarctica and surrounding area showing the location of the station Molodezhnaya.

While I was in Antarctica, 60 M-100 meteorological rockets were launched from Molodezhnaya and 16 of these carried an additional wind sensor ('chaff') for determining the mesospheric winds. Most of the flights were successful and the average rocket apogee reached was 86.93 km. A summary of the chaff-borne flights, evenly distributed throughout 1972,

is given in Table 1. The results derived for the region 50–90 km (mostly for the 60–80 km layer in the upper mesosphere) are presented here. This is the first meteorological study of the upper mesospheric winds carried out in Antarctica.

The chaff used consisted of cylindrical aluminium-coated glass fibres having a diameter of about 0.025 mm. About 400 g of chaff, in a special container divided into two parts, was ejected at rocket apogee. The descending chaff cloud was then tracked by a high sensitivity Meteor-2 radar. Table 1 gives the corresponding wind tracks of all such flights. At the time of ejection at rocket apogee, above 80 km, the chaff fell at a high speed, about 160 m s<sup>-1</sup>, but as it descended further it slowed down to about 4 m s<sup>-1</sup> at around 56 km because of the greater density and viscosity of the air at lower altitudes.

The radar data on the drift of the trajectory of the chaff are used to measure the wind speed and direction in the mesospheric region under study. Corrections for changes in the wind with altitude are also applied. The accuracy in measuring the wind speed at higher altitudes is about 6-10 m s<sup>-1</sup>. Time-height cross sections for zonal and meridional winds are plotted using the conventional interpolation method in Figs 2 and 3.

The zonal components over Molodezhnaya, Antarctica, show that in the upper mesosphere the winds were predominantly easterly in the summer half and westerly in the winter half. In January and February (southern summer, Fig. 2) the speeds of the easterly winds ranged from 10 to 50 m s<sup>-1</sup> in the 60-80 km region for which the chaff data were available. On January 26, 1972, however, the zonal wind structure was found to have a small core of weak westerlies with wind speed about 10-15 m s<sup>-1</sup> in a narrow altitude region from 77 to 85 km. In February the easterly winds were stronger and attained a maximum speed of 96 m s<sup>-1</sup> at 82 km. During March there was only one rocket flight and during April there were none. During the first week of May, westerly winds of about 20 to 60 m s<sup>-1</sup> were detected. During the second week of May, however, the winds again became strong easterlies with a maximum speed of 113 m s<sup>-1</sup> at 66 km and a secondary maximum of 79 m s<sup>-1</sup> at 80 km.

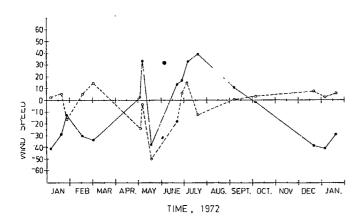

Fig. 4 Zonal flow (—) obtained by averaging winds from the individual soundings over a 10-km layer centred at 75 km (Mesospheric Circulation Index, MsCI). ---, Meridional flow. Positive values refer to west and south components.

Wind speeds in m s<sup>-1</sup>.

In June and July (southern winter) a westerly jet was formed which attained a maximum speed of 157 m s<sup>-1</sup> at 64 km and became weaker at higher altitudes. The strong westerly winds started to weaken in September-October (southern spring) in the 60-70 km region and weak easterlies started developing above 70 km. There were no ascents with chaff payloads during August and November. In December the zonal flow was characterised by easterlies of about 20-40 m s<sup>-1</sup>.

The meridional cross section of the winds shows that they were of variable nature (Fig. 3). In January weak southerly winds of about 5–15 m s<sup>-1</sup> predominated in the upper mesosphere. In February the winds were mainly northerlies, ranging from 5–25 m s<sup>-1</sup>. In May the northerly winds became stronger and formed a jet which had a maximum speed of 88 m s<sup>-1</sup> at around 60 km, with a secondary maximum of 79 m s<sup>-1</sup> at 78 km. In the narrow region 65–70 km there was a small core of southerlies having a maximum speed of 57 m s<sup>-1</sup> at 68 km.

In June and July the northerly winds changed to southerly ones with a maximum speed of 48 m s<sup>-1</sup> at 64 km. In September and October the winds were mainly southerlies of about 10–60 m s<sup>-1</sup> with lower values at around 60 km and higher values at around 82 km. There was a core of weak northerlies at around 75 km. In December the meridional flow was characterised by weak southerlies of about 5–15 m s<sup>-1</sup>.

The seasonal reversal of winds at different times of the year can be shown clearly by a method devised by Webb¹. In analysing the Meteorological Rocket Network (MRN) data Webb¹ calculated an average flow over a layer 10 km thick centred at 50 km and called it the Stratospheric Circulation Index (SCI) of the appropriate layer. Adopting the same method, I have computed mean values of the wind speeds in m s⁻¹ obtained from the individual soundings by averaging over a 10-km layer centred at each of the altitudes 65, 70, 75 and 80 km (Table 1). Since this presents an average flow of the mesosphere under study, it is termed the Mesospheric Circulation Index (MsCI). Its values for the 70–80 km layer centred at 75 km, MsCI, are plotted in Fig. 4.

In conclusion, I found that zonal winds were predominantly easterly in the summer half and westerly in the winter half whereas the meridional winds were variable. From the analysis of the MsCI (Fig. 4) it is obvious that the summer easterly flow changed to a westerly flow in the first week of May, followed by a rapid reversal to an easterly flow in the second week. The easterly flow again changed to westerly flow in mid June. The meridional flow (Fig. 4) also showed a rapid shift

from northerlies to southerlies in the last week of June. The southerly flow again rapidly changed to northerly flow in mid July. These rapid shifts in both zonal and meridional components indicated a sudden 'explosive' change in temperature distribution which might have occurred in the upper mesosphere. I am at present investigating this phenomenon. The winter westerly flow changed to the summer easterly flow at about the end of September. It seems that both for the zonal and the meridional flows the summer—winter shift was a rapid and dramatic change, whereas the winter—summer shift was slow and unspectacular. I am also studying diffusion phenomena in the mesosophere using the chaff data.

I acknowledge the collaboration of the members of the 17th Soviet Antarctic Expedition, 1971–73, and thank the Hydrometeorological Service of the USSR and the Department of Atomic Energy, Government of India, for allowing me to take part in the expedition, and giving me the privilege of being the first Indian Explorer of Antarctica, which was made possible by the late Professor Vikram A. Sarabhai. I also thank Professor P. R. Pisharoty for stimulating guidance and encouragement.

# Flow near an oscillating cylinder in dilute viscoelastic fluid

There are many natural phenomena in which nonlinear interactions of time-dependent inputs give rise to steady—that is, time-independent outputs. One of these is a steady streaming belonging to a class of secondary flows sometimes called acoustic streaming. It occurs when a circular cylinder oscillates normal to its axis in an unbounded Newtonian fluid<sup>1-3</sup>. We report here on the steady secondary flow induced when a long thin cylinder oscillates as described in a viscoelastic liquid. We found that the direction of steady streaming is opposite to that found for the bulk of fluid when the experiment is performed with a Newtonian fluid.

Reversal of secondary flow has been noted in several flows<sup>4-6</sup> when fluid has been altered from Newtonian to viscoelastic behaviour.

Our experimental apparatus (Fig. 1) was adapted from that used by Bertelson et  $al^3$ . The oscillating brass cylinder was 6.72 cm long, and had a diameter of 1.6 mm. It was suspended on two bronze leaf springs, each 0.15 mm thick. The oscillating system was contained in a cylindrical glass container 9.55 cm long and 7.05 cm in diameter. The glass container was mounted in a strong, fixed magnetic field. Oscillation was induced by an alternating current (Fig. 1).

The container was filled with test fluid containing tracer particles (hollow glass spheres  $40-60~\mu m$  in diameter). Pathlines representing steady secondary streaming were obtained by photographing particles in a plane perpendicular to the axis of the vibrating cylinder. Only the secondary flow appears in the photographs because illumination is provided by a stroboscopic source synchronised with the frequency of oscillation.

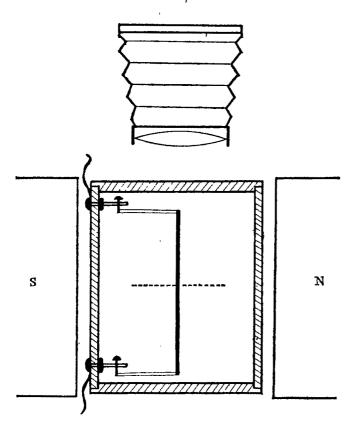

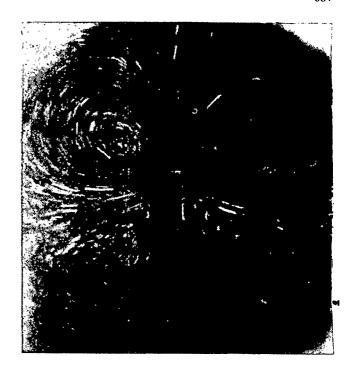

Fig. 1 Schematic diagram of apparatus. Dotted line indicates plane of illumination. S and N, Magnets.

Photographs were first taken with a Newtonian test fluid: a 50% by weight solution of glycerine in water. The viscosity of the liquid was approximately  $6 \times 10^{-3}$  N s m<sup>-2</sup>. The oscillating frequency was set at 45 Hz. For small amplitudes of oscillation (approximately 25% of the cylinder diameter) the results shown in Fig 2a were obtained. There are two regions of flow (see ref. 3). In the inner region near the oscillating cylinder the pathlines form small closed vortices with fluid flowing toward the oscillating cylinder in the direction of oscillation and away from it in the transverse direction (Fig. 2b). Of more predominance is the outer region which also contains closed vortices but with an opposite sense of rotation. Thus, the predominant secondary flow is away from the oscillating cylinder along the axis parallel to the direction of oscillation. (At lower Reynolds numbers a thicker inner vortex system can be obtained?.)

The contrast is striking when the results of Fig. 2 are compared with those of a dilute viscoelastic fluid possessing drag reducing properties<sup>8</sup>. The secondary flow shown in Fig. 3 was obtained under conditions similar to those cited for Fig. 2 with one exception. The glycerine-water solution contained 0.01% by weight of Dow Separan AP30, a water-soluble polyacrylamide. No small inner vortex is visible in Fig. 3, and the predominant secondary flow is toward the oscillating cylinder along the axis parallel to the direction of oscillation. These results could signify that the small inner vortex observed with the Newtonian fluid is greatly enlarged in the experiments performed with polymer solution.

In Figs 2a and 3a there is an asymmetry between upper and lower portions of the photographs. That is because the cylinder motion was not truly rectilinear, but followed an arc determined by the radius of the spring supports. The experiment of Fig. 3a was performed at a slightly higher amplitude causing more predominant curvature.

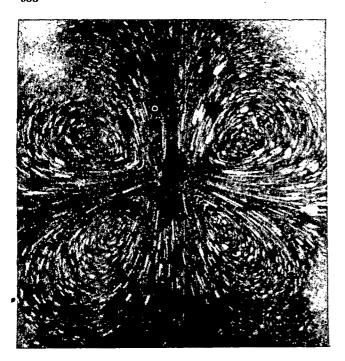

As the addition of 100 p.p.m. of Separan has little effect on the shear viscosity of the glycerine-water solution, the drastic change in secondary flow probably results from the elasticity of the Separan solution.

 $\boldsymbol{a}$ 

Fig. 2 Steady secondary flow for Newtonian fluid: 50% by weight glycerine in water. Frequency of oscillation, 45 Hz. a, Tracer photographs at f/2.8 and 1 s exposure time, showing inner and outer vortices; b, sketch drawn from a showing direction of circulation. Double arrow, direction of cylinder oscillation.

b

Further experiments with varying amounts of Separan showed that the reversal of flow persisted to very dilute solutions. Secondary flow characteristic of Newtonian flow only reappeared when the Separan was reduced to 10-20 p.p.m.

Hopefully, this new phenomenon may be helpful for characterisation and, perhaps, further elucidation of the nature of dilute solutions of drag reducing polymers.

## Taylor vortex instability and annulus length effects

THE stability of the flow between rotating cylinders has both fundamental and technological significance. The classical analysis by G. I. Taylor<sup>1</sup> of the stability of the circumferential laminar flow deals with coaxial cylinders for which the length L is infinite and the radial clearance  $c=R_2-R_1$ , is small, but subsequent work2 has eliminated the need for the small clearance approximation. The flow, once unstable, takes the form of axisymmetric toroidal vortices and these Taylor vortices can in turn become unstable with the onset of non-axisymmetric wavy vortices. Early analysis of this instability³ was again restricted to coaxial cylinders of infinite length and small clearance, but Eagles4 has produced a stability analysis avoiding the small clearance approximation and has applied it to a cylinder radius ratio  $R_1/R_2=0.951$ . No stability analyses seem to exist for an annulus of finite length and most experimental workers choose to work with long cylinders even though short cylinders are more likely to be encountered in engineering applications. Recently I described some observations<sup>5</sup> of vortex sizes in short annular clearances and I noticed the apparent absence of wavy vortices in those experiments: now I have more positive evidence of the considerable effect of annulus length on the wavy vortex critical speed.

The present flow visualisation results are for a rotor of diameter 91.42 mm concentrically positioned inside a Perspex stator of bore 103.2 mm, thickness 19 mm and effective length 250 mm, so that  $R_1/R_2=0.894$ . Vortices in the test fluid, a silicone oil of kinematic viscosity v=19.3 centistoke, were made visible by adding a small quantity of aluminium particles of typical maximum dimensions 0.01 mm. Given a high standard of control of rotor speed (N revolutions s-1) and fluid temperature, this commonly-used visualisation technique enabled the critical speeds to be determined repeatedly to better than

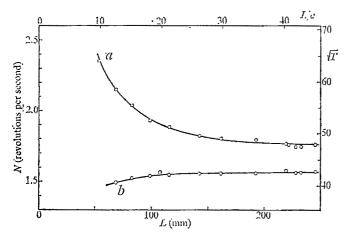

Fig. 1 Effect of annulus length L on critical speeds N determined from visual observations. a, Wavy vortices; b, Taylor vortices.  $R_1/R_2 = 0.894$ .

 $\pm 0.5\%$  in general, with no hysteresis apparent for speed increasing and decreasing. Annulus length was varied by changing the depth of the test fluid, and the end boundary conditions were asymmetric, with the lower end a stationary solid surface and the upper a free liquid surface. Table 1 shows that observed critical speeds are in satisfactory agreement with calculated values for the maximum annulus length tested. Figure 1 shows that length has a small effect on the speed at which Taylor vortices appear but a marked effect on the speed at which wavy vortices appear: at L/c=25 the second critical speed is about 10% higher than the calculated value and at L/c=10 about 40% higher.

To achieve greater length: clearance ratios, observations were also made using a rotor of diameter 94.45 mm inside a stator of diameter 100.01 mm, giving a radius ratio  $R_1/R_2$ 0.954. The silicone oil viscosity was v=6.10 centistoke at the controlled operating temperature. Here, critical speeds were determined from measurements of the torque reaction on the stator which was supported on externally-pressurised air bearings: the onset of Taylor vortices produced an upward discontinuity in the slope of the torque-speed relationship as speed was increased in small steps and the onset of wavy vortices produced a later and less pronounced downward discontinuity. This method also gave good results, repeatable to better than  $\pm 0.5\%$  at larger lengths but with slightly diminished accuracy at short lengths where the slope changes became somewhat rounded. For L/c < 10, the Taylor critical in particular was less certain as the torque-speed relationship became nonlinear and slightly concave upwards before the major change of slope occurred: the latter was taken as the critical

condition. The results, shown in Fig. 2, are generally similar to those in Fig. 1 although the very small variation in the Taylor critical speed with length is of opposite sign to that in the visualisation experiment. The critical speed for the onset of wavy vortices begins to rise appreciably as L/c values are reduced below 40 and the maximum value measured was about 22% above the minimum. Table 1 shows that observed critical speeds at the maximum L/c value of 107 are in satisfactory agreement with theoretical values.

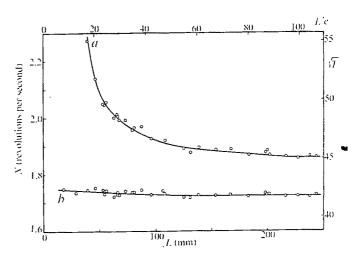

Fig. 2 Effect of annulus length L on critical speeds N determined from torque measurements. a, Wavy vortices; b, Taylor vortices.  $R_1/R_2 = 0.954$ .

These visualisation and torque observations at two different cylinder radius ratios agree in indicating little effect of annulus length on the critical speed for the onset of Taylor vortices but considerable effect on the critical speed for the onset of wavy vortices. The length; clearance ratio needed to avoid a rise of more than say 5% in the second critical speed is about 35 but more measurements are required before a precise estimate can be made. Additional preliminary experiments suggested that a similar limit applies when the cylinders are eccentrically positioned, eccentricity raising both critical speeds. Evidently the assumption of infinite length in stability theory is far less satisfactory for the wave instability than for the Taylor instability, and the observation by Coles<sup>6</sup> on the relationship between the two critical speeds requires re-examination in terms of length effects.

#### Early turbulence and drag reduction phenomena in larger pipes

SOLUTIONS of certain high molecular weight polymers have been shown to exhibit the phenomena of both early turbulence1-7 and drag reduction4.5.8 depending on whether the measurements were made under laminar flow conditions for the former case or under turbulent flow conditions for the latter. In general, early turbulence has been observed only in capillary tube flows while drag reduction has been observed in a variety of flow geometries, the only requirement being a developing or developed turbulent flow field.

A correspondence of sorts between early turbulence and drag reduction was surmised earlier<sup>9</sup> and was also strongly implied by capillary tube measurements where a continuous transition between early turbulence onset points and drag reduction onset had been observed. A close relationship between the two phenomena was therefore suggested<sup>5</sup>. Specifically, the non-Newtonian onset point (either early turbulence or drag reduction) for 1 p.p.m. solutions of Polyox coagulant in a series of salt solutions were found to be described by the following empirical relationship in these capillary flows

$$\tau^* = (78.7)/(1 - 1.39M)$$

where  $\tau^*$  is the non-Newtonian onset point and M the molarity of the magnesium sulphate salt solution.

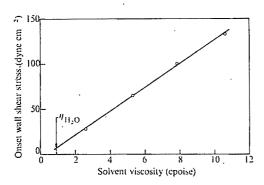

Fig. 1 Onset of early turbulence for 100 p.p.m. WSR-205 solutions in glycerine-water mixtures. Pipe diameter, 0.553 cm.

The suggestion has been made<sup>2</sup> that early turbulence might also be observed for flows in larger diameter tubes provided sufficiently high wall shear stresses could be attained in the laminar flow regimes. This hypothesis was confirmed by subsequent experiments in larger diameter pipes with drag reducing additives dissolved in water-glycerine mixtures<sup>6,7</sup>; the glycerine serving the function of significantly altering the solution viscosity, thus providing the needed higher wall shear stresses in laminar flow conditions. Figure 1 shows the variation of the onset wall shear stress for early turbulence with solvent viscosity for 100 p.p.m. WSR-205 solutions in glycerine-water mixtures in a 0.553 cm pipe. The plot is essentially linear over the range of solvent viscosities chosen. The linear relationship suggests that an extrapolation might justifiably be made to the pure water case. Thus, a hypothetical value of 7.4 dyne cm<sup>-2</sup> is obtained for the onset of early turbulence in this particular pipe for the water case had the flow not undergone transition to the turbulent regime. Data<sup>8</sup> are also available for the same WSR-205 sample under turbulent flow conditions in pure water. Figure 2 shows a plot of the drag reduction onset wall shear stress against the log concentration. Although 100 p.p.m. WSR-205 had not been studied in the earlier work a short extrapolation

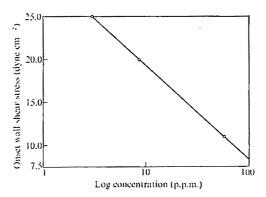

Fig. 2 Onset of drag reduction against log concentration for WSR-205 solutions in turbulent flow. Pipe diameter, 0.660 cm.

of the linear plot in Fig. 2 to the 100 p.p.m. value yields an onset wall shear stress for drag reduction of approximately 8 dyne cm<sup>-2</sup>. Although both sets of data rely on short extrapolations this additional evidence does seem to support earlier claims4,8,9 that drag reduction and early turbulence are somewhat related phenomena.

### Preserved amino acids from silicified protein in fossil Radiolaria

THE discovery of amino acids in fossils1 has stimulated a wide range of biochemical studies<sup>2,3</sup> over the past 20 yr with implications for evolution, geochronology, and biomineralisation. One productive line of evolutionary investigation has been the analysis of calcified protein from Recent shells of calcareous invertebrates such as molluscs<sup>4,5</sup> and planktonic Foraminifera<sup>6,7</sup>. Results indicate that the amino acid composition is speciesspecific and varies in a systematic manner which parallels morphology. Moreover, data from extinct 18-Myr-old Foraminifera suggest that the technique can be applied directly to the deepsea fossil record for establishing phylogenetic affinities6.7. Virtually nothing is known, however, of the nature of the organic matrices which may exist in fossil skeletons composed of silicia rather than calcium carbonate. Amino acid data from this study are therefore believed to be the first evidence reported for the presence and diagenesis of silicified protein in the fossil record.

Radiolaria, important contributors to the siliceous ooze characteristic of Equatorial Pacific and Antarctic regions, were

Core samples were disaggregated in a dilute sodium hexametaphosphate solution with ultrasonic vibration, washed with distilled water on a 62 µm sieve, and air dried. Although the skeletons of these planktonic protozoans are generally small (50-500  $\mu m$ ), certain species were found to be sufficiently large and abundant to allow manual extraction from the coarse fraction under a binocular microscope. Samples from aggregate species were exhaustively cleaned ultrasonically in a series of sodium hexametaphosphate washes and distilled water rinses, dissolved in cold hydrofluoric acid, evaporated to dryness, and hydrolysed in 6 N HCl in sealed tubes under nitrogen at 110° C for 22 h. Hydrolysates were evaporated to dryness in a vacuum centrifuge and stored in a freezer until analysed. Suitable species were not found in sufficient abundance for replicate analyses and results are therefore based on single analyses. Analyses of sub-mg monospecific collections of low-density skeletons (2-5 µg per skeleton) were made possible with a Durrum D-500 amino acid analyser operated in manual mode at the pmol ( $\sim 10^{-10}$  g) level of sensitivity. Reproducibility is within  $\pm$  5% based on replicate analyses of standard amino acid mixtures. Results in Tables 1 and 2 are corrected for reagent blank values and hydrolytic losses of Thr and Ser.

the first group of silica-secreting organisms chosen for study. All species analysed are members of the Polycystina group which are currently defined as "Radiolaria with skeletons of opaline silica without admixed organic compounds", based on earlier microscopic evidence, Before this study, only the Tripylea group was thought to contain skeletal organic matter. Tripyleans are rarely preserved in deep-sea sediments because of their fragile structure.

Two of the three Recent species analysed (Spongoplegma antarcticum Haeckel and Spongotrochus glacialis Popofsky) were isolated from the top of an Antarctic deep-sea core (RC12-229), the third (Cyclampterium neatum Sanfilippo and Riedel) from the top of an Equatorial Pacific core (RC12-66). Down-core species (Cyclampterium neatum and Dictyastrum angulatum Ehrenberg) were separated from RC12-66 at the palaeomagnetic boundary of Gilbert/Epoch 5 which corresponds to an age of 5.1 Myr.

A protein-containing organic matrix was found in all three species of Recent Radiolaria (Table 1). With the exception of cystine, all amino acids normally found in protein hydrolysates were present. Proline was detected, but not quantified, with the 590-nm photometer in the analyser. Two additional amino acids, p-alloisoleucine and ornithine, were found in significant amounts indicating that some diagenesis had occurred in the few thousand years represented by the core top samples.

Each species has a unique composition with inter-species variations being greater than experimental error for 16 of the 17 amino acids. Glycine, aspartic acid, glutamic acid, and alanine are the four most abundant amino acids in all three species and account for 60% of all residues.

The only notable difference between the two spumellarian species and the single nassellarian is a 73% lower abundance of lysine in the nassellarian skeletons. The Spumellaria and the Nassellaria are the two major taxonomic groups within the Order Polycystina<sup>8</sup>.

Total amino acid concentration in silicified radiolarian skeletons is about half the content of calcified foraminiferal shells (Table 1). Significant differences are also observed in the proportion of certain amino acids although the four most abundant acids in both mineral types are glycine, aspartic acid, glutamic acid, and alanine. The relative abundance of aspartic and glycine is reversed in the two groups with glycine being greater in Radiolaria (aspartic second), whereas aspartic acid ranks first in

Foraminifera (glycine second). Other major compositional differences are 77% more lysine, 46% less threonine, 35% less tyrosine, and 34% more leucine in radiolarian skeletons.

Approximately 75% of the total amino acid content is peptidebound. Analyses of non-hydrolysed samples of Recent Spongoplegma antarcticum and Spongotrochus glacialis show total 'free' amino acid concentrations amounting to 25% of the hydrolysed values. As Recent planktonic Foraminifera show less than 5% 'free' amino acid content (K.K., unpublished), diagenesis of proteins seems to be accelerated in siliceous skeletons. Experiments with Recent foraminiferal protein indicate that the hydrofluoric acid dissolution step does not contribute significantly to the observed hydrolysis in Radiolaria.

Comparative analyses of samples from Recent and 5.1-Myrold species (Table 2) indicate that the protein-containing organic matrix undergoes severe diagenesis over geological time. An 88% reduction in amino acid content was found when the 5.1-Myr-old sample of nassellarian Cyclampterium neatum was compared with a Recent sample. A substantial reduction (46%) was also observed in the pair of spumellarians. If the diagenetic product, ornithine, is excluded from the comparison, the effect is more similar for the two groups, with reductions of 69% (Spumellaria) and 89% (Nassellaria). Scanning electron micrographs suggest that the substantially higher diagenetic rate in the nassellarian is related to a greater susceptibility to solution because of a nodulose skeletal surface11.

The 'free' amino acid content of a non-hydrolysed 5.1 Myr nassellarian sample represents only 19% of the total content on hydrolysis, whereas 77% of the acids from a hydrolysed spumellarian sample of the same age is accounted for by 'free' acids11. These results suggest that the bulk (80%) of the remaining few amino acids in the nassellarian are in bound form and may represent either well-protected intact protein or humic acid-type polymers from in situ reactions12.

The diagenetic reductions of 69% (Spumellaria) and 89% (Nassellaria) in 5.1-Myr-old samples are in marked contrast to an average reduction of 40% observed in 18-Myr-old Foraminifera6,7. Factors which may contribute to the accelerated diagenetic rate of Radiolaria are (1) the high internal water content (up to 20% by weight) of opaline silica<sup>13</sup> promoting the hydrolysis of peptide bonds, and (2) greater skeletal porosity leading to more rapid attack and leaching by external pore waters in the sediment.

Contamination of fossil materials by amino acids in the sediment is always a potential problem because of the ubiquitous nature of these compounds. As a test for surface contamination in situ, samples of S. antarcticum and S. glacialis were treated with concentrated (30%) hydrogen peroxide for 1 h before normal sample preparation. No significant differences in composition were observed between these samples and those cleaned with only sodium hexametaphosphate.

The presence of a protein-containing matrix in radiolarian skeletons provides a rationale for extending amino acid studies to siliceous fossils. Promising lines of investigation would include the dating of siliceous sediments by the epimerisationracemisation reactions of preserved amino acids14,15 and the tracing of evolutionary lineages by the analysis of speciesspecific amino acid patterns7.

I thank Dr J. D. Hays for stimulating my interest in Radiolaria, Dr P. E. Hare for helpful discussions and Elizabeth Sajewicz for technical assistance. This work was supported by grants from the National Science Foundation and by a postdoctoral fellowship from the Geophysical Laboratory, Carnegie Institution of Washington.

### Search for selectivity between optical isomers in reactions of polarised positive muons with alanines and octanols

ONE of the most intriguing problems in chemical evolution is the origin of optical asymmetry in biopolymers. The easiest way to state the problem is: why are proteins made almost exclusively of L-amino acid optical isomers and natural sugars of D-optical isomers? That proteins must be made of only one kind of optical isomer is understandable on the basis of their need for precise three-dimensional conformations in order to perform their catalytic roles as enzymes. But, is it just a matter of chance, as suggested in refs 2-4, that our proteins are L-, or is there (was there) some asymmetrical agent on our planet that made the protein L-configuration the one upon which life is based?

One possible 'non-chance' explanation stems from the unequal decomposition of optical isomers5.6 and the appearance of optical activity in the products of light-mediated reactions<sup>7-10</sup> in circularly polarised light. A slight excess of right-circularly polarised light in sunlight reflected and/or refracted in the Earth's magnetic field<sup>11</sup> could produce overall optical asymmetries. But laboratory experiments have detected such effects only for high intensities of circularly polarised light; this mechanism has therefore been seriously questioned as an explanation for the origin of optical asymmetry in biological molecules1.

Table 1 Residual muon polarisation in various media							
Target	Residual asymmetry (A)	Residual polarisation* (Pres)					
Distilled water	$0.153 \pm 0.003$	$0.55 \pm 0.03$ (def.)*					
0.67 M racemic alanine in water	$0.151 \pm 0.004$	$0.54\pm0.03$					
Solid L-alanine	$0.089 \pm 0.003$	$0.32\pm0.02$					
Solid D-alanine	0.089 ± 0.003	$0.32 \pm 0.02$					
Liquid L-2-octanol	$0.140 \pm 0.003$	$0.50 \pm 0.03$					
Liquid D-2-octanol	$0.140 \pm 0.002$	$0.50\pm0.03$					

<sup>\*</sup> Residual polarisation derived from  $P_{\text{res}} = A/A_{\text{o}}$ , where  $A_{\text{o}} = 0.278 \pm 0.016$  is calculated by comparing  $A(\text{H}_2\text{O})$  with the independently determined residual polarisation in water,  $P_{\text{res}}(\text{H}_2\text{O}) = 0.55 \pm 0.03$  (ref. 18).

Abelson, P. H., Carnegie Inst. Wash. Yb., 53, 97-101 (1954), <sup>2</sup> Hare, P. E., in Organic Geochemistry, 438-463 (Springer-Verlag. New York, 1969).

A second possible 'non-chance' explanation invokes spinpolarised electrons and associated bremsstrahlung emitted in the  $\beta$ -decay of certain natural radioactive nuclides<sup>12,13</sup>. One report claims that in aqueous solution D-tyrosine is decomposed by <sup>90</sup>Sr  $\beta$  emission faster than L-tyrosine<sup>14</sup>. This report has been questioned by later papers<sup>15,16</sup>, however, and must be considered unsubstantiated.

This paper is concerned with a search for optical selectivity in the interaction of a new agent, the polarised positive muon, with organic molecules. The degree of spin polarisation in muon beams produced from decaying pions is typically about 80% (refs 12 and 13). As far as we are aware, this is a higher degree of polarisation than that of any particles previously used in the search for selectivity of interactions with optical isomers. Since polarised muons are known components of cosmic rays<sup>19</sup>, a selective interaction, possibly leading to selective destruction of one optical isomer, might provide another 'non-chance' explanation for the particular appearance of L-amino acids and D-sugars in living cells.

Positive muons, upon slowing down, form the neutral atom 'muonium' ( $\mu^+$  e<sup>-</sup>, or Mu)<sup>20</sup> which is analogous to the hydrogen atom, except for its mass,  $m_{\rm Mu}=0.1131m_{\rm H}$ . Because of the high degree of polarisation of the  $\mu^+$  'nucleus', the formation of the muonium atom and/or its subsequent chemical reactions might vary between optical isomers. We have, however, been unable to detect any optical selectivity in the interactions of muonium with either (1) solid D- and L-alanine or (2) liquid D- and L-2-octanol.

The  $\mu^+$  beam of the Berkeley 184-inch cyclotron was used in these experiments. The quantity actually measured was the 'residual polarisation' of muons stopped in the various substances. Although the muons enter the target with a well-defined spin polarisation, their polarisation after stopping is dramatically dependent upon the chemical properties of the medium in which they come to rest.

The spin polarisation of the muons is easily detected through their decay products: the muon decays by way of

$$\mu^+ - \cdot e^+ \, \nu_e \, \overline{\nu}_u$$

with a mean lifetime of 2.2  $\mu$ s. The positron (e<sup>+</sup>) from the decay is, on the average, about twice as likely to be emitted in the direction of the  $\mu^+$  spin as in the opposite direction<sup>17,18,21</sup>. An ensemble of polarised positive muons thus broadcasts its polarisation in a shower of fast (up to 50 MeV) positrons. By detecting these positrons in scintillation counters, we monitor the magnitude of the  $\mu^+$  polarisation. In the present experiments, a perpendicular magnetic field is applied, causing the  $\mu^+$  spin to precess at its Larmor frequency. A counter telescope fixed in the plane of precession is most likely to detect a positron if the muon decays when its spin points towards the telescope; thus the e<sup>+</sup> detection probability in that telescope will rise and fall as the muon polarisation sweeps past it<sup>18</sup>.

The measured amplitude of the resultant time oscillation of the positron detection probability is called the experimental asymmetry, A, and is proportional to the residual polarisation of the  $\mu^+$ ,  $P_{res}$ 

$$A = A_0 P_{\rm res}$$

The constant of proportionality  $A_0$  is an empirical constant unrelated to the chemical properties of the medium<sup>22,23</sup>. The values of  $P_{res}$  obtained in the present work are given in Table 1. Since water has been thoroughly studied<sup>22,23</sup>, the value of  $P_{res}$  (H<sub>2</sub>O) = 0.55  $\pm$  0.03 from refs 22, 23 is used to calibrate the results listed in Table 1. A more detailed technical description of the apparatus and experimental technique can be found in refs 18, 22 and 23.

Each target consisted of about 500 g of the substance under study. The solid alanines (A grade) were obtained from Calbiochem, La Jolla, California, and the liquid octanols from Norse Laboratories, Santa Barbara, California. All samples were used without further purification.

In most condensed media, any residual polarisation observed through muon precession is the result of chemical reactions of muonium with molecules of the medium; in the absence of such reactions, all the muon polarisation is lost within a few nanoseconds through the so-called "muonium mechanism". This depolarisation mechanism arises after the formation of muonium and is due to the contact hyperfine interaction between  $\mu^+$  and  $e^-$  magnetic moments, which couples the two spins together so as to reverse the  $\mu^+$  spin within  $\sim 10^{-10}$  s. Fast precession of muonium in the external magnetic field conspires with this hyperfine coupling to effectively depolarise the  $\mu^+$  in muonium within  $\sim 10^{-9}$  s. The only way a muon can be spared this fate is if the Mu atom that it forms reacts chemically with a molecule of the medium to incorporate the  $\mu^+$  into a diamagnetic molecule.

A rigorous theoretical description of the mechanism of  $\mu^+$  depolarisation is found in refs 22–24. Briefly, there are two sorts of chemical reactions of Mu that prevent complete depolarisation of the  $\mu^+$ : (1) 'normal' thermal reactions, which occur after the Mu atom has thermalised and started depolarising the  $\mu^+$ ; and (2) epithermal or 'hot atom' reactions, which occur while the Mu atom is still slowing down, long before any depolarisation has taken place. The latter reactions are assumed to be important in the energy region from  $\sim 10$  eV down to thermal energies, and are usually the dominant channel for reactions of Mu in all but the most reactive substances. In water or methanol, for instance, the residual polarisation is believed to be due exclusively to hot atom reactions<sup>22,23</sup>.

As can be seen from Table 1, the residual polarisation in a 0.67 M solution of racemic alanines in water is the same, within experimental uncertainties, as that observed in pure water. We conclude that there is little, if any, thermal reaction of Mu with alanine molecules, at least in solution 22,23. Taken with the observation that Mu has a large epithermal reaction probability in most organic substances, this suggests that the residual polarisation in the solid alanines is primarily a result of hot atom reactions of muonium. The same assumption can be made for the octanols, on the somewhat weaker grounds that Mu has a large, purely epithermal reaction probability with methanol 22,23.

The data in Table 1 show that there is no significant difference between the reaction probabilities of polarised Mu atoms with enantiomers of alanine and 2-octanol. The errors given are derived from the fitting procedure (see refs 22 and 23). Although it is statistically possible that a few per cent difference could be realised ( $\Delta A/A = 0.0 \pm 0.05$  for alanine and  $\Delta A/A = 0.0 \pm 0.03$  for 2-octanol), this difference could only be determined accurately on the basis of more measurements. Remembering that it is the  $\mu^+$  nucleus of the Mu atom that is polarised (negligible polarisation is transmitted to the electron in the time of  $\sim 10^{-12} \, \mathrm{s}$  that muonium takes to thermalise), it is perhaps not surprising, in retrospect, that the hot atom reactions are optically indiscriminate.

A more sensitive test of optical selectivity of polarised muons may be possible if muonium precession can be observed directly in these substances. Apparently, recent results using positrons<sup>25</sup> suggest that electrons picked off by muons to form Mu atoms might be expected to have an optically-influenced polarisation. This effect would be reflected in first order in the amplitude of muonium precession signals. The feasibility of such studies is now being considered.

#### Bilayers at the air—water interface?

FILMS of octadecanol and the corresponding C<sub>18</sub> acid (stearic acid) appear to occupy 10° A2 per molecule at the air-water interface when spread from ethanol or acetone, as opposed to 20 A°2 per molecule when spread from a (non-polar) solvent such as hexane or benzene. Ries1 has proposed that in a polar or non-polar spreading solvent the amphipathic molecules adopt a bimolecular configuration with the hydrophilic groups pointing, respectively, outward and inward. It was further postulated that when spread at an air-water interface, only the latter could be 'unzippered' by the substrate to form a monolayer. Spreading from a polar solvent would thus result in bilayer formation and explain the apparent loss of half the film molecules. In view of the upsurge of interest in membrane and model membrane systems, the possibility of forming a lipid bilayer at the air-water interface was certainly exciting and clearly warranted further investigation.

Films of L-α-dipalmitoyl phosphatidylcholine (DPPC), 1-monoolein and stearic acid (Applied Science Laboratories; purities > 99 %) were selected for study. DPPC and 1-monoolein are examples of substances which do, and do not, readily form a bilayer2. Isotherms and surface potentials for spread films of these three substances are shown in Figs 1-3. Shifting from hexane to ethanol resulted in a substantial decrease in the apparent area per molecule for all three films, the extent of the decrease being dependent on the nature of the film molecules when other factors were held constant. The large shift to smaller areas per molecule occurs between 90 and 100 volume per cent ethanol (Fig. 4a). Between 0 and 90 mol per cent ethanol, the

already liquid-expanded isotherms become slightly more expanded at low surface pressures and the surface potentials appear to decrease slightly (Fig. 1), both effects indicating the presence of small amounts of ethanol in the substrate<sup>4</sup>. Contrary to Ries1, the large shift in areas per molecule was sensitive to changes in solute concentration (Fig. 4b) and even to the rate of delivery at the air-water interface. In effect, a 50% decrease in apparent area per molecule can be obtained simply by selecting the correct spreading solute concentration for that particular component. Of particular interest, is the surface potential which showed little change on transition from monolayer to 'bilayer'. In addition both phase changes and compressibility are independent of the apparent physical state of the film. These latter observations led us to question seriously the assigned bilayer configuration for films spread with polar solvent and to attempt to respread an original stearic acid 'bilayer' as a monolayer using a non-polar solvent.

The respread isotherms initially revealed gross contamination and great care was required before hexane-respread films (originally spread either from hexane or ethanol) were impurity free. When

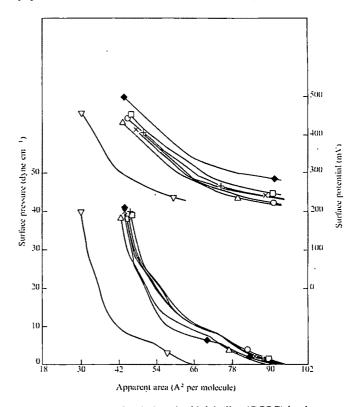

Fig. 1 L-α-Dipalmitoyl phosphatidylcholine (DPPC) isotherms at the air-water interface (pH 6 substrate) at 22° C. Films spread at the air—water interface (pri o substrate) at 22°C. Finits spread from various mixtures of ethanol and hexane. Percentage ethanol:  $\phi$ , 10;  $\Box$ , 44;  $\bigcirc$ , 50;  $\times$ , 60; +, 70;  $\triangle$ , 90;  $\bigcirc$ , 100. Isotherms and surface potentials were continuously recorded. The upper curves are the surface potentials. Spreading solvent concentration approximately 0.15 mg DPPC per ml solvent. Ethanol and hexane were column purified and distilled before use. Hydrochloric acid used in the aqueous substrate was also distilled. Water was double-distilled from glass (the first time from alkaline permanganate) and subsequently double-distilled from quartz. An automated continuous recording teflon trough film-balance was used, which together with initial film spreading techniques, has been described elsewhere<sup>3</sup>. Techniques were developed for the removal, concentration, solution and respreading of initially spread films after it was found that adding Ing of initially spread films after it was found that adding solvent to a spread monolayer or bilayer clearly indicated solvent retention. Scrupulous care in cleaning glassware, trough and solvents were required for reproducibility in such experiments. Reproducibility for initially spread films was  $\pm$  0.5 A<sup>2</sup> per molecule for a given surface pressure ( $\pi$ ) and  $\pm$  10 mV for surface potential values. Reproducibility in areas per molecule on respreading from ethanol a film initially spread from hexane was approximately  $\pm$  5% at a value of 15% less than the originally spread film. The initial spread film was never compressed beyond 15 dyne cm<sup>-1</sup>. Respreading films with hexane, originally spread from ethanol, gave values with some 10% or less film loss.

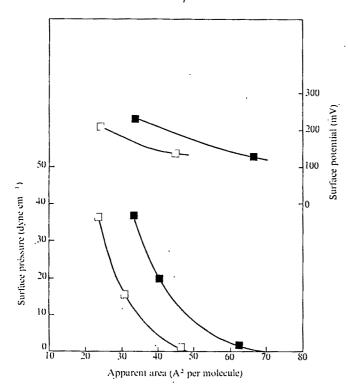

Fig. 2 1-Monoolein isotherms at the air—water interface spread from ethanol (☐) and hexane (☐) at 21.5° C. (pH 6 substrate). Spreading solvent concentration approximately 0.1 mg 1-monoolein per ml solvent.

this was achieved (Fig. 3), respread areas per molecule were usually slightly lower ( $\sim 10\,\%$ ) than the original film values. For films previously spread from ethanol, slightly high areas per molecule were obtained by removing significant amounts of the aqueous substrate with the original film. Only when high solute concentrations were used, were areas per molecule obtained for a respread film that were slightly greater than those for the original 'bilayer'. Immediately after film removal the substrate appeared clean, but after an hour or so, however, trace amounts of stearic acid were once again obtained. These additional amounts did not arise from collapsed material

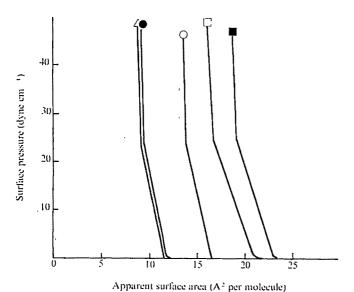

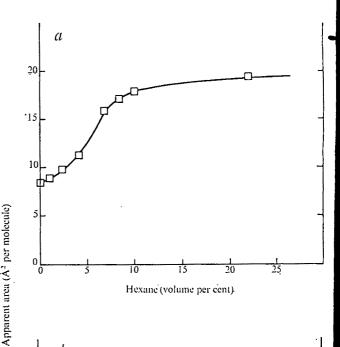

Fig. 3 Stearic acid films at the air-water interface spread from hexane ( $\blacksquare$ ) and respread with hexane ( $\square$ ); from ethanol ( $\bullet$ ) and respread with hexane ( $\triangle$ ); from ethanol at  $pH\ 2\ (\bigcirc$ ). Substrate at  $pH\ 6$  except where indicated. Initial spreading solvent concentration approximately 0.21 mg stearic acid per ml solvent.

at the trough edge. Finally, addition of acid to the substrate before initial spreading from ethanol led to areas per molecule intermediate between those of a 'bilayer' and a monolayer (Fig. 3). A similar, though smaller, effect was obtained by adding salt to the substrate.

From the above, we conclude that spreading of a film with a polar solvent does not result in the formation of a bilayer, but in fact leads to the loss of a significant amount of material, the precise amount depending on the nature of the film material, spreading solvent, the substrate pH and ionic strength, and also on the spreading solvent concentration and rate of deposition. The effect of the substrate additives indicates that film loss occurs through the substrate.

We have observed two phenomena which help explain these results: (1) Substantial film loss is accompanied by gross Teflon trough contamination. A clean trough permits rapid, complete water drainage. After multiple ethanol depositions and film

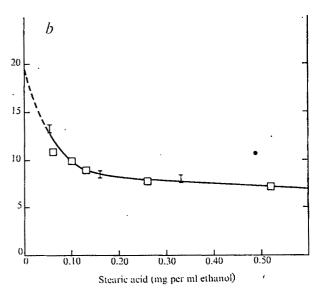

Fig. 4 a, Apparent area per molecule of stearic acid as a function of spreading solvent composition. A 0.29 mg stearic acid per ml ethanol solution was diluted with hexane to give the stated ethanol-hexane ratio prior to spreading at 20.5° C. b, Apparent area per molecule of stearic acid as a function of its concentration in ethanol at 20.5° C. The zero abscissa value was obtained by spreading from hexane. Points marked (1) were obtained by at least three determinations. Points marked (1) were obtained by preparing the most concentrated solution and then carrying out a series of dilutions.

loss, water film retention on the trough was greater than normal. (2) Schlieren patterns are readily observed during ethanol spreading at the air-water interface, penetrating deeply into the water. This behaviour is greatly reduced by the addition of small amounts of hexane. We postulate, therefore, that most of the lost film material is trapped at the Teflon surface. The well known porosity of Teflon provides a substantial surface area for this purpose. Certainly it is not located at the air-water

We conclude that spreading from a polar solvent results in substantial film loss but that the residual film is still a monolayer; the near identical surface potential, phase changes and compressibility, independent of spreading solvent, all support this conclusion.

We wish to acknowledge the financial assistance of the United States Heart and Lung Institute in the completion of this work.

## *In vivo* nuclear fission in the aetiology of decompression sickness

THERE can be little doubt that gas bubbles accompany and may well cause decompression sickness, as the effect of recompression is usually to alleviate the symptoms' and to eliminate the new reflectors of ultrasound which appear in man and animals during decompression<sup>2-5</sup>

As gas bubbles do not form in supersaturated fluids or animals without gas micronuclei<sup>6,7</sup> we assume that the body of a normal man must contain microbubbles, which may expand at decompression to give the observed effects. Furthermore, it seems that such microbubbles must be created continually. Some studies of bubble formation in vivo<sup>8-16</sup> assume implicitly the presence of pre-existing micronuclei, which evades the problem.

One mechanism for the production of micronuclei in man, tribonucleation, has been suggested by Ikels<sup>11</sup>. We suggest here that some gas micronuclei are created in man by spontaneous nuclear fission (SF) in vivo. Ionising particles dissipate energy along their tracks and if the linear energy transfer (LET) to a metastable liquid is sufficiently high, the resultant 'thermal spike'12 may nucleate bubbles which can subsequently grow to visible size, as in the bubble chamber.

Water is rarely used in bubble chambers13, though persistent microbubbles should be created in cold water which is sufficiently supersaturated with gas and subjected to radiation.

As we were unable to find any report of radiationinduced nucleation of aqueous solutions supersaturated with gas leading to bubbles of visible size, we have studied the stability of solutions of two  $\alpha$ -active radioisotopes in cold, supersaturated water.

Polypropylene outer containers from Brunswick disposable 1 ml syringes (capacity 12 ml) were filled with stabilised distilled water saturated with air at 215 pound inch<sup>-2</sup> gauge (14.7 bar), (see ref. 15). The top 2 ml of liquid was removed from each tube, 1 ml of solution (Table 1) was introduced, and the tube was topped up with liquid paraffin and sealed by a thin polythene sheet. The tubes then received high hydrostatic pressure treatment to eliminate any gas micronuclei introduced with the additions. The final gas tension in the amended tubes was about 13.1 bar. The tubes were then removed for observation at atmospheric pressure for 6 h. If visible bubbles appeared in any tube during this period it was recorded as unstable; the other specimens were recorded as stable.

Most of the control tubes remained stable for the full 6 h and the tubes with the lead salt were no less stable than the controls (Table 1). We may, therefore, conclude that a heavy metal ion does not necessarily promote bubble formation. The tubes containing uranium were, however, much less stable than the controls, the difference being statistically significant ( $\chi^2 = 208$ , P < 0.0005).

To distinguish between the effects of the principal mode of radioactive decay for 238 U (α emission) and the much less frequent spontaneous nuclear fission, thorium tubes were prepared. The quantity of salt was arranged so that the  $\alpha$ emission was the same as in the uranium tubes, and the  $\alpha$ energies are similar. The SF halflife of 232Th (ref. 16) is so much greater than that for 238U (ref. 17) that the probability of one event for all 100 thorium tubes in 6 h is less than  $10^{-2}$ .

The thorium tubes were only marginally less stable than the controls (Table 1); the difference between the thorium and uranium results is again highly significant ( $\chi^2=93$ , P < 0.0005). We conclude, therefore, that the nuclear fragments which are liberated by SF of 238U will nucleate bubbles which can grow to visible size in cold supersaturated water.

It may not be widely appreciated that spontaneous nuclear fission occurs in man. The phenomenon seems to occur, however, sufficiently often to maintain a stock of stable gas micronuclei in an average man, and exceptionally it may promote bubble formation during one decompression.

The principal isotope must be 238U, of which the body of an average man in the UK contains about  $110 \,\mu g$  (ref. 18).

		results	٠.	Weight of	f addition	α	activity	SF	SF

<sup>\*</sup> Uranium oxalate. † Thorium nitrate.

If the SF halflife of 238U is 1018 yr (ref. 17) man should experience a disintegration about once every three weeks.

A new nucleus might not survive compression, But if each disintegration during decompression, or during the preceding period at raised ambient pressure were to cause an attack of decompression sickness, a large group of men working eight-hour shifts at pressure should experience a bends rate of about 2.2% of man-decompressions. At the Tyne Road Tunnel men were working for some months at pressures of 27-29 pound inch-2 gauge. Of the 5,465 mandecompressions recorded after shifts of 8 h or more at these pressures, some 118 resulted in an attack of bends<sup>19</sup>, giving a rate of 2.16%.

One mechanism for the stabilisation of new nuclei is an 'organic skin'20,21, though in our case high temperatures are involved so fission-induced cavities may well be surrounded by a coagulavelum<sup>22</sup> of denatured protein. Certainly, an abundant supply of suitable macromolecules is to be found in most body fluids. The body burden of uranium resides mostly in bone<sup>18,23</sup>. The commonest symptom of acute decompression sickness (the bends) is described as a diffuse pain associated with bones, and the most important chronic consequence of hyperbaric exposure is Caisson disease of bone. In dogs, the ends of the long bones retain more uranium than the shaft<sup>23</sup>, and both in dog<sup>23</sup> and in man<sup>24</sup> the element is mainly found on the surfaces of cancellous bone and the endosteum. Both are sites associated with the lesions of Caisson disease of the femur and humerus.

There can be considerable geographical variation in the total  $\alpha$  activities of human bone ash samples<sup>23</sup>. If a similar variability in the uranium content—and therefore in the formation rate of fission-induced nuclei-could be discovered and correlated with the observed variation in individual susceptibility to decompression sickness, it may become possible to prove or refute our hypothesis. From our comprehensive records of diving experience and work in compressed air26 it is easy to select men who are particularly resistant or susceptible, though estimation of the body burden of uranium in live men without occupational exposure is less easy. The traditional method is to determine the uranium content of urine<sup>27,28</sup>, and despite uncertainty in relating the excretion rate to body burden, it seems probable that body burdens may be compared usefully in this wav.

#### Pleistocene date for man in Tasmania

THE Pleistocene colonisation of Tasmania has long been predicated1,2 but no dated human occupation sites of that age have been reported before. The excavation of a cave site on Hunter Island<sup>3</sup>, 6 km off the coast of north-western Tasmania (40° 34'S, 144° 45'E; Fig. 1) has yielded the first radiocarbon date of Pleistocene age from a human occupation site in Tasmania.

The Cave Bay Cave is a large sea cave in a slate cliff containing an undisturbed deposit rich in faunal remains and with signs of human occupation. In a preliminary cutting 1.75 m deep, the top 25 cm were found to contain abundant evidence of man: hearths, lenses of marine shell and quartz flakes were present, and the bones of seabirds predominated. Below this level, evidence of human occupation was sparse. The deposit was still rich in faunal remains but seabirds were absent whereas native rodents and small marsupials were

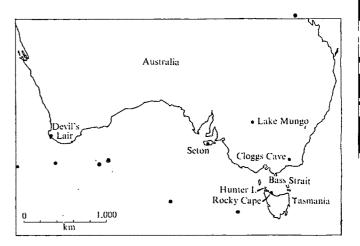

Fig. 1 Southern Australia.

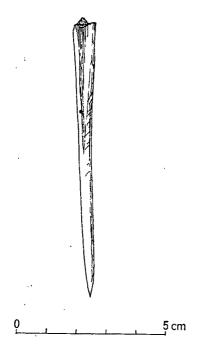

Fig. 2 Bone point found in Pleistocene deposits in Cave Bay

abundant. There were also some larger marsupials, some of which are not now found on Hunter Island, including the native cat (Dasyurus cf. viverrinus). A bone point and two pieces of flaked quartz-convincing evidence of the presence of man-were found between 80 and 100 cm below the surface. The bone point is a ground and polished piece of macropod fibula (Fig. 2). Associated charcoal has been carbon dated to  $18,550\pm600$  b.p. (ANU-1361).

The final maximum of the last glaciation was responsible for lowered sea levels about 18,000 yr BP and Hunter Island would have been a hill on a land bridge between Tasmania and the Australian mainland4.

Similar sites in southern Australia with Pleistocene dates, bone artefacts and good faunal preservation are Clogg's Cave at Buchan in south-eastern Australia (17,720 ± 840 b.p., ANU-1044)5, the Seton site on Kangaroo Island, South Australia (16,100 $\pm$ 1,000 b.p., ANU-1221; ref. 6 and R. J. Lampert, personal communication), and the Devil's Lair, Western Australia (24,600 ±800 b.p., SUA-31)7. All of these sites have been the haunt of non-human predators who have contributed their own share of faunal remains. In the Cave Bay Cave, the abundant remains of rodents and small marsupials in the lower levels were probably deposited as pellets regurgitated by owls, and the native cat has probably contributed the bones of larger animals such as bandicoots and possums, which show distinct signs of non-human gnawing.

At Clogg's Cave, the Seton site and the Devil's Lair, there is evidence of the presence of the Tasmanian wolf and devil (Thylacinus cynocephalus and Sarcophilus harrisii) although there is so far no sign of them at the Cave Bay Cave. The immediate difficulty generated by the presence of these carnivores is that of discriminating the food remains of man from those of the other predators.

A more intriguing problem is suggested by a comparison between these sites and post-Pleistocene cave sites; for instance, the Rocky Cape sites of north-western Tasmania<sup>1</sup>. There, a total of 6 m of shell midden deposit has built up over the last 8,000 yr and there is no evidence of the presence or action of predators other than man (ref. 1 and Rhys Jones, personal communication). There is generally much sparser evidence of human occupation at the older sites in terms of artefacts and stratigraphic features than at Rocky Cape. It seems that Pleistocene man in southern Australia made less intensive use of cave and shelter sites than his post-Pleistocene descendants. Another important human occupation site of Pleistocene age and with faunal remains preserved is at Lake Mungo-an open site where people camped on the beaches of a lake8.

The Cave Bay Cave has implications not only for an understanding of the ancestry and development of the unique Tasmanian culture2, but also for the ecology of Pleistocene man in Australia.

This investigation is part of a project supported by the Australian National University<sup>3</sup>.

## Identification of metabolic dechlorination of highly chlorinated biphenyl in rabbit

CHLOROBIPHENYLS with one to four chlorine atoms per molecule are metabolised by certain animals, plants and microorganisms but the more highly chlorinated biphenyls are rather resistant to metabolic change<sup>1</sup>.

Organochlorine compounds may be identified at low concentrations in crude extracts of natural samples by a high resolution mass spectrometric method involving photoplate detection2-4. The method is based on the facts that first, in conditions of high resolution each ion of unique molecular composition is recorded individually and, second, the relatively large mass deficiencies (the actual mass being lower than the closest nominal mass) of both chlorine isotopes. The accurate mass for <sup>35</sup>Cl for instance is 34.9688 which accounts for a mass deficiency of  $-31.1 \times 10^{-3}$  mass units (m.u.), the the corresponding value for 37Cl being -34.1×10<sup>-3</sup> m.u. These mass deficiencies cause the exact mass of ions which contain these atoms to be at lower masses than ions of the same nominal mass which contain only atoms (that is C, H, N, O) present in most biological molecules. Thus, the high resolution photoplate technique is capable of detecting chlorine-containing mass deficient ions in crude biological extracts. As the photoplate acts as an integrating ion detector it is possible to identify compounds present in low concentrations (\leq 0.01 p.p.m.).

This method has now been applied to the unambiguous identification of metabolites from organochlorine compounds' including the detection of trace components. After the usual dosing of the animal, urine, faeces or organs to be examined were extracted with a suitable solvent and a small portion (10-20  $\mu$ g) of the dried extract was placed in the mass spectrometer sample tubes. Mass spectra from the sample were then obtained by exposing photoplates to ions derived from the crude extract for up to 30 min or

## YOUR FUTURE IN ELECTRON OPTICS...

## WILL YOU WANT YOUR LABORATORY TO BE UP-TO-DATE, WITH A MINIMUM OF INVESTMENT?

Of course you will. But, with advances in electron optics coming so often these days, keeping current without bending the budget isn't as easy as it used to be.

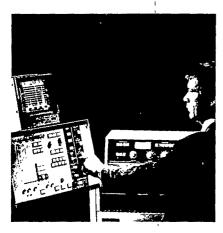

In theory, the secret lies in always having as much electron optical capability as you need... but never any more than you need. In finding a way to continuously match the job to be done with the instruments available. In building an ability in electron microscopy precisely suited to the requirements of today... yet fully adaptable to those of tomorrow.

Too much to expect? Not at all. In fact, whatever your needs... now or later... there's a Philips instrument for you now!

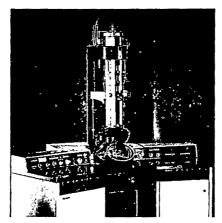

Do you want non-specialist operators to produce more really high-quality micrographs in less time? The EM 201C. Do you want to enjoy the benefits of SEM without the usual complications? The PSEM 500. Do you want to do X-ray microanalysis on transmission specimens? Try TEAM. Do yoù want to experiment with STEM and SEM without buying a new instrument? The EM 301 plus S(T)EM Unit. Quantitative image analysis? Quantimet.

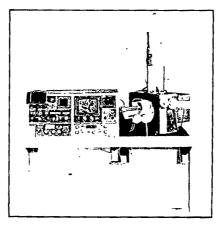

And this list is only part of Philips systems approach to the future Read more about it in our brochure.

## Tomorrow's electron optics... today!

**PHILIPS** 

## Fossil and Living Dinoflagellates

William A. S. Sarjeant

December 1974, x+182 pp., £5.00/\$13.00.

0.12.619150.6

The result is a work which, for the first time, provides a comprehensive review of available information on fossil dinoflagellates, and which discusses all aspects of the biology of living dinoflagellates likely to be of direct or indirect relevance to the understanding of fossil forms. It will be enthusiastically received by universities and colleges and in particular by commercial companies especially within the oil industry. Individual palynologists, biologists and geoloists as well as organisations engaged in marine research or geological surveys will also find this book to be of great value.

Proceedings of the Serono Foundation Symposium No. 3

## **Platelet Aggregation and Drugs**

edited by Luciano Caprino and Ennio C. Rossi

December 1974, xii+298 pp., £5.80/\$15.25. 0.12.158950.1

Platelets may play a major role in occlusive vascular disease, and for this reason the control of platelet function by means of inhibitors of platelet aggregation may substantially decrease the morbidity and mortality associated with these conditions. In this book there are chapters by leading investigators on the physiology and chemistry of platelet aggregation, the pharmacology of platelet aggregation inhibition and data on newly discovered inhibitors, the newer methodologic approaches to the study of platelet function, and the relationship of platelet aggregation to clinical states such as arteriosclerosis, hypertension and diabetes mellitus.

## **Human Intestinal Flora**

B. S. Drasar and M. J. Hill

December 1974, xii+264 pp., £6.50/\$16.75.

0.12.221750.0

The first section of the book provides a discussion of the remarkable progress made in the last fifteen years in our knowledge of intestinal flora in health and disease. In the second section the enormous subject of biochemical activities is tackled, and the final section brings the flora and their metabolism together in the examination of some selected disease states. This unique work in a fast-growing field will be of great value to gastroenterologists, biochemists and bacteriologists, and may also be of much use to pharmacologists and toxicologists.

## **Foundations of Quantum Dynamics**

S. M. Blinder

December 1974, x+226 pp., £6.50/\$17.25.

0.12.106050.0

In this monograph, Professor Blinder examines the mathematical formalism of nonrelativistic quantum dynamics. He describes the structure and foundations of this formalism in detail, emphasizing fundamental principles rather than concrete applications, but still slanting his approach towards application in the areas of molecular physics and quantum chemistry. The work should prove extremely useful as an intermediate text to span the gap between elementary wave mechanics and more advanced techniques. It will appeal to postgraduate students and advanced under-graduates in physics and chemistry, and to research workers involved with chemistry, molecular physics, spectroscopy and molecular structure.

## Tissue Culture and Plant Science 1974

Proceedings of the Third International Congress of Plant Tissue and Cell Culture held at the University of Leicester, Leicester, England, 21st-26th July, 1974

edited by H. E. Street

December 1974, xii+502 pp., £7.50/\$19.75.

0.12.673350.3

In this volume, reviews by nineteen international experts cover the full range of this recent work, each review introducing a particular field of study in which plant tissue and cell culture techniques have proved of key importance. They indicate the most active areas of current research and also the barriers to immediate progress, whether these lie with the need for better experimental systems or for advances in the techniques of culture.

## **Aberrations of the Symmetrical Optical System**

W. T. Welford \*\*

December 1974, x+240 pp., £7.60/\$20.00.

0.12.742050.9

This book provides a systematic development of geometrical optics and the optical aberration theory needed for optical design. The author provides only that material which is useful to designers with access to computers. Methods designed for outmoded computational techniques and those simply not well adapted for practical design purposes have been ignored, and the author has emphasised finite methods. This is one of the first books on aberration theory which is aimed mainly at working optical designers, and while intended primarily as a reference work, it contains some material which has previously only been published in research journals.

## The Psychology of Animal Learning

N. J. Mackintosh

December 1974, xiv+730 pp., £8.00/\$18.50.

0.12.464650.6

This book provides a comprehensive and detailed treatment of the procedures, results and interpretation of psychological studies of learning in animals, covering the original and the most up-to-date experiments and theories. There are chapters on all the major topics in the field and over 2,000

Contents:

Introduction. Classical conditioning: basic operations. Classical conditioning: theoretical analysis. Instrumental learning: basic operations. Analysis of appetitive instrumental learning. Instrumental learning: avoidance and punishment. Contrast effects. Extinction. Generalization. Discrimination. References and author index. Subject index.

## **Natural History Photography**

edited by D. M. Turner Ettlinger

December 1974, xxxviii+396 pp., (9" X7", 64 plates) £8.80/\$23.25. 0.12.703950.3

Natural History Photography discusses photographic techniques for a wide range of subjects, from big game to insects, caves and plants, and will be of the greatest interest to all photographers, whether professional or amateur, as well as to biologists and naturalists who wish to use photography as a means of recording their subjects.

Many of the techniques described in this book have not received much attention in previous literature and so will be of particular interest; these include very high speed-flash, stereo-photography, the use of play-back tape and cave photography.

London Mathematical Society Monographs No. 4 Series Editors: P. M. Cohn and G. E. H. Reuter

## Sieve Methods

H. Halberstam and H. E. Richert

December 1974, xiv+364 pp., £9.80/\$26.00.

0.12.318250.6

This, the first book to be devoted to sieve methods, breaks new ground by describing clearly and in detail an area which has tended to be up to now the preserve of a handful of experts.

Introduction. The sieve of Eratosthenes: formulation of the general sieve problem. The combinatorial sieve. The simplest Selberg upper bound method. The Selberg upper bound method (continued): O-results. The Selberg upper bound method: explicit estimates. An extension of Selberg's upper bound method. Selberg's sieve method (continued): a first lower bound. The linear sieve. A weighted sieve: the linear case. Weighted sieves: the general case. Chen's theorem. Bibliography. References.

## The Cell In Medical Science

edited by Felix Beck and John B. Lloyd

December 1974, xviii + 598 pp., £11.30/\$29.25. 0.12.084202.5

Contents:

Cellular Genetics and Development: Biochemical genetics. General mammalian cytogenetics. An introduction to human cytogenetics. Sex chromatin. The kinetics of cell production. Cell differentiation. Cell growth and morphogenesis. Ageing.

Cellular Specialization: The neurone. The synapse. Satellite cells of neurons. The skeletal muscle cell. The muscle spindle. The smooth muscle cell. Author index. Subject index.

## The Physiology and Pathophysiology of the Skin Volume 3

edited by A. Jarrett

December 1974, xviii+448 pp., £13.00/\$34.50. 0.12.380603.8

The Physiology of the Dermis: The chemistry and molecular biology of collagen. The elastic tissue of the Physiology of the Dernis: The chemistry and molecular blology of collagen. The elastic tissue of the dermis. The physical nature of the dermis in living skin. The comparative biology of collagenous tissues. Ageing of the dermis. The Pathophysiology of the Dermis: The collagenoses. Cutaneous elastoses. Vasculitis. Dermal cell populations and their pathological responses. The Dendritic Cell Population of the Epidermis: Melanin and melanocytes. Embryonic origin and abnormalities of melanocytes. The biochemistry of pigment formation. Pathological disturbances of pigmentation. The Langerhans cell. Melanoma. Author Index. Subject Index.

longer, each at different temperatures (fractional distillation). The developed photoplates were then screened for metabolites (mass deficient ions) manually or by using an automatic photoplate reader coupled with a computer.

Rabbits were fed a diet of food pellets containing 1% 2,2',4,4',5,5'-hexachlorobiphenyl. The feeding time was 7 d and the total concentration of chlorobiphenyl administered was 1 g kg<sup>-1</sup>. The urine, which was collected during the entire feeding period, was extracted with ether and the extract treated in the manner described earlier. Manually measured data (perfluorokerosene as internal standard, experimental values < 10 p.p.m. from calculated values) showed the presence of two major metabolites (Fig. 1, I, II) formed from the hexachlorobiphenyl by hydroxylation and hydroxylation with concomitant dechlorination respectively. A third, minor, metabolite corresponding to a molecular composition IH was detectable only in a limited number of photoplate exposures at about 60° C.

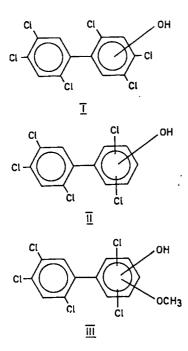

Fig. 1 Metabolites of 2,2',4,4',5,5'-hexachlorobiphenyl.

Figure 2 shows the partial mass spectrum (enlarged photoplate record) of the crude ether extract exposed for 10 min at 60° C. The very mass deficient ions (> 0.1 m.u.) corresponding to the organochlorine metabolites are seen, clearly resolved at lower mass in each cluster of lines corresponding to ions of the same nominal mass. At m/e 370 and m/e 372 the molecular ion (M<sup>+</sup>; that is molecular weight calculated with <sup>35</sup>Cl) and M+2 ion for compound III are visible. Measurement of the exact mass of the 37Cl isotope peak (M+2 ion) further confirmed the composition of the compound. At m/e 374 in addition to the weak M+4 peak of compound III a strong line corresponding to compound I is evident. At m/e 375 and m/e 376 lines for the <sup>13</sup>C and <sup>37</sup>Cl isotope peaks of I are obvious.

The advantages of this method in the study of metabolism of organochlorine compounds seem to be first, that no radioactive labelling is necessary because the chlorine atoms act as tracer, second, the method is simple and rapid with unambiguous results so that large scale screening is possible, and third, the danger of loss of metabolite or degradation during separation procedures is minimised and non-volatile products can be detected much more readily than by GC-MS. The usefulness of the method may be con-

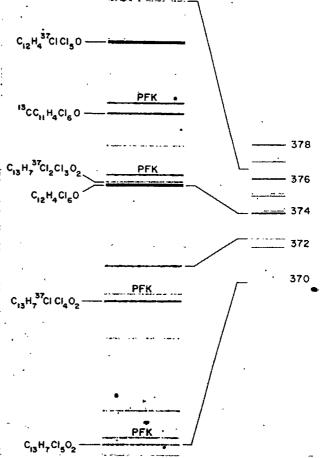

Fig. 2 Partial mass spectrum (m/e 370-376; enlargement)of photoplate record) of crude ether extract from rabbit urine. Animals were dosed with 2,2',4,4',5,5'-hexachloro-biphenyl. Lines corresponding to compound III are C<sub>13</sub>H<sub>7</sub>Cl<sub>3</sub>O<sub>2</sub>(M<sup>+</sup>; m/e 370); C<sub>13</sub>H<sub>7</sub><sup>37</sup>Cl Cl<sub>4</sub>O<sub>2</sub>(M<sup>+</sup>+2; m/e 372). Lines corresponding to compound I are C<sub>12</sub>H<sub>4</sub>Cl<sub>6</sub>O(M<sup>+</sup>; m/e 374); C<sub>12</sub>H<sub>4</sub> <sup>37</sup>Cl Cl<sub>3</sub>O(M<sup>+</sup>+2; 376); <sup>13</sup>CC<sub>11</sub>H<sub>4</sub>Cl<sub>6</sub>O(<sup>13</sup>C isotope peak of M<sup>+</sup>; m/e 375). ### Variation in assortative mating in two colonies of Arctic skuas

THE Arctic skua is a polymorphic seabird with pale, intermediate and dark plumaged phenotypes. Sexual selection of the phenotypes takes place when pairs are being formed; during the breeding season the darker males generally mate before the paler males<sup>1,2</sup>. This gives them a selective advantage because a pair which breeds earlier in the season will fledge a greater average number of chicks<sup>1,3</sup>. Computer models have been used to estimate the females mating preferences for the darker males<sup>3</sup>.

Assortative mating also takes place between the phenotypes. In previously published data<sup>4</sup>, which were taken from observations on several colonies by different ornithologists, the intermediates and darks were not distinguished from each other and were lumped into a single class of dark birds. Some colonies showed assortative mating with a significant excess of pale  $\times$  pale and dark  $\times$  dark matings compared with the frequencies to be expected if pairing were random. Other colonies showed no deviation from random mating. These differences in assortative mating are not statistically significant, however: an orthogonal analysis gives  $\chi^2 = 10.09$  with 6 degrees of freedom corresponding to P = 0.13. In this paper we give new evidence of assortative mating, showing that in one colony pale birds mate assortatively while in another intermediates mate assortatively.

Table 1 Observed numbers and theoretical frequencies of matings of Arctic skuas on Fair Isle and Foula in Shetland

Mating type	of ma	ed no. tings Foula	. , Theoretical frequencies
Pale $\times$ pale	7	23	$\alpha u + [(u^2(1-\alpha)^2)/(1-\alpha u - \beta v - \gamma w)]$
Pale × inter	24	30	$2uv(1-\alpha)(1-\beta)/(1-\alpha u-\beta v-\gamma w)$
Pale × dark	12	22	$2uw(1-\alpha)(1-\gamma)/(1-\alpha u-\beta v-\gamma w)$
Inter × inter	48	42	$\beta v + \left[ v^2 (1-\beta)^2 / (1-\alpha u - \beta v - \gamma w) \right]$
Inter × dark	17	38	$2vw(1-\beta)(1-\gamma)/(1-\alpha u-\beta v-\gamma w)$
Dark × dark	8	10	$\gamma w + \left[ w^2 (1-\gamma)^2 / (1-\alpha u - \beta v - \gamma w) \right]$
Total no.	116	165	1 .

To derive the theoretical frequencies, it is assumed in the model that the pale, intermediate and dark phenotypes occur in the proportions u, v and w and mate assortatively with another bird of the same phenotype in the proportions  $\alpha$ ,  $\beta$  and  $\gamma$ . Thus the proportion of all birds that mate at random is  $1 - \alpha u - \beta v - \gamma w$ .

Research on the colony of Arctic skuas on Fair Isle began in 1948 and continued until 1962. In 1973 we started further researches in order to analyse the components of natural and sexual selection which the earlier research had revealed. In 1974 we also surveyed the Arctic skuas on Foula, an island in the Shetlands 66 km north-west of Fair Isle. The survey was

carried out by systematically quartering the breeding grounds and observing which pair of birds attacked or feigned injury in a particular area. The data of the numbers of breeding pairs are shown in Table I with theoretical frequencies given by a model of assortative mating analysed previously. In the model, a proportion of the birds of each phenotype mate assortatively with others of similar phenotype; the remaining birds mate at random. Pale, intermediate and dark birds mate assortatively in the proportions  $\alpha$ ,  $\beta$  and  $\gamma$ . Female preferences generally determine assortative matings, but the model allows for both male and female preferences.

If the intermediates and darks in the data of Table I are lumped together, the analysis of  $\chi^2$  is similar to the analysis of the data published earlier. There is a significant overall deviation from random mating, but not in the Fair Isle data alone. This difference between the colonies is not itself significant. If the intermediates and darks are separated, however, the data of both Fair Isle and Foula show very significant deviations from random mating, but in different directions. The parameters  $\alpha$ ,  $\beta$  and  $\gamma$  of the general model of assortative mating have been fitted to the data by maximum likelihood. The effects on χ<sup>2</sup> of fitting the different parameters are shown in Table 2. Fitting the single parameter  $\beta$  to the Fair Isle data reduces the value of  $\chi^2$  to less than the degrees of freedom.  $\chi^2$  is further reduced, but not of course significantly, by fitting the additional parameter y. Fitting the parameter a to the Foula data similarly reduces  $\chi^2$  to an insignificant value and fitting  $\beta$  reduces it still further. Our data are thus explained if 47% of intermediates mate assortatively on Fair Isle and 32% of pales mate assortatively on Foula.

These inferences are confirmed by the log likelihoods and support limits given in Table 3. Unless  $\beta$  is fitted to the Fair Isle data and  $\alpha$  to the Foula data, the log likelihoods are always more than two units of support below the maximum. The support limits show the precision of the maximum likelihood estimates of these parameters.

What might explain the differences we have found and what consequences may follow? O'Donald4 suggested that imprinting might be the explanation but found there was no evidence for imprinting in data on the matings of parents and the subsequent matings of their chicks. If imprinting were a cause of the females' mating preferences, it would produce neither the strong assortative mating of intermediates on Fair Isle, nor the difference between the colonies. An alternative explanation would be a genetic difference between the colonies in mating behaviour. This might have arisen by chance as a 'founder effect', or evolved by selection if pairs differ in breeding success on the islands. Birds fledged in one colony sometimes breed in other colonies, however; and if this migration is random, it must reduce any genetic differences between colonies. The variation in assortative mating thus presents a remarkable evolutionary problem for future researches.

Assortative mating has the effect of reducing heterozygosity.

Table 2	Estimation of	the parameters	$\alpha$ , $\beta$ and $\gamma$ in t	he mo	dels of asso	rtative mating fo	or the Arctic ski	as of Fair Isle a	nd Foula
Parameters estimated	Arctic skuas of Fair Isle ML estimates			Arctic skuas of Foula ML estimates					
	_	ameters	$\gamma^2$		d.f.	of par	ameters	χ <sup>2</sup>	d.f.
None		_	9,950		3	· -		11.556	3
α	0.1	102	9.110		2	0.3	316	1.923	2
β	0.4	174	1.385		2	0.2	276	6.802	2
γ	0,2	237	5.797		2	0.0	)15	11.501	2
α and β	0.0	0.475	1.385	•	Ī	0.288	0.180	0.538	1
$\alpha$ and $\gamma$	0.089	0.233	5.485		ī	0.315	0.0	1.923	1
$\beta$ and $\gamma$	0.437	0.165	0.111		1	0.275	0.0	6.801	1

The maximum likelihood (ML) estimates were found by calculating the log likelihood (base e) for a given set of values of the parameters. Random variations in the values were then introduced until a higher log likelihood was obtained. This process was repeated with smaller and smaller random variations until the maximum likelihood was reached. Explicit solutions of the equations for maximum likelihood can be obtained if in addition to the phenotypic frequencies only one parameter is to be estimated. The explicit solutions give the same values as those found by the random search.

Table 3 The log likelihoods and support limits of the estimated parameters

a,	Arctic skuas of Fair Isle Parameters estimated	Maximum la	a likalihaad
	i arameters estimated	Maximum lo	
	0		$og L_{max}$
	β		1,754
	β and γ	-18	
	$\alpha$ , $\gamma$ , $\alpha$ and $\gamma$		3.625
	Support for $\beta$ relative to log I	$L_{max} = -181.75$	4
	Units of support	Value	s of β
		Upper	Lower
		limit	limit
	3 units	0.692	0.097
	2 units	0.660	0.184
	I unit	0.613	0.283
ь.	Arctic skuas of Foula		
•	Parameters estimated	Maximum lo	g likelihood
	a		3.028
	α and β		2.364
	$\beta$ , $\gamma$ , $\beta$ and $\gamma$	28	
	Support for a relative to log I	$L_{\rm max} = -283.02$	
	Units of support	Value	
	Omits of support		
		Upper	Lower
	2	limit	limit
	3 units	0.523	0.069
	2 units	0.488	0.117
	l unit	0.441	0.177

The levels of support are units of log likelihood below the maximum log likelihood. For example, for the Fair Isle skuas, the 2-unit support limits are the values of  $\beta$  for which log L=-183.754, being two units of log likelihood below the maximum when the one parameter, β, is estimated. If variation is normally distributed, the 2-unit limits correspond to the limits  $\pm 2\sigma$ , where  $\sigma$  is the standard error of the estimate. The variation in these estimates, is however, not normal and the limits are not symmetrical, although the difference between the upper and lower 2-unit limits is approximately 40. The difference between these limits would be exactly 40 if the variation were normal.

O'Donald<sup>5</sup> showed that at equilibrium the frequency of the heterozygotes is given by the solution of the equation

$$[(1-\frac{1}{2}\beta)(\frac{1}{2}\alpha-\beta+\frac{1}{2}\gamma)-\frac{1}{2}(\alpha-\beta)(\gamma-\beta)]v^2+[(1-\frac{1}{2}\beta)(1-\alpha p-\gamma q)-q(\alpha-\beta)(1-\gamma)-p(\gamma-\beta)(1-\alpha)]v-2pq(1-\alpha)(1-\gamma)=0$$

where p and q are the gene frequencies and v is the frequency of the heterozygotes. To apply this formula to the Arctic skuas, we must assume that the intermediates are the heterozygotes6. There is in fact a continuous range of variation from intermediates to completely dark birds. In our present work we have classified as intermediate any bird with at least some paler feathers on the nape. Dark birds seem to be homozygous by this classification. Using our estimates of the parameters, we predict that the frequencies of heterozygotes at equilibrium should be 0.4748 on Fair Isle and 0.4563 on Foula, compared with the actual frequencies of 0.5905 and 0.4606 respectively. The predicted frequency is very close to the actual frequency on Foula, but very significantly different from it on Fair Isle. Indeed, on Fair Isle, there is a significant excess of intermediates over the numbers of heterozygotes expected by random mating. This may indicate that natural selection favours heterozygotes on Fair Isle or that differential migration has occurred and equilibrium has not yet been reached.

Assortative mating differs from sexual selection only to the extent that the mating preferences are restricted to individuals of the same phenotype as that which is preferred. Assortative mating and sexual selection will have similar selective effects as a result of female mating preferences: the preferred males will gain an advantage because they will mate earlier in the breeding season. The preferences have been estimated from the Fair Isle data of breeding dates of pale, intermediate and dark males3. In the model with the highest likelihood, 18% of the females prefer dark males and 29% prefer intermediate males. Using our present data, we have estimated that 47% of the matings of intermediates are assortative. These matings are probably caused by the preference of intermediate females

for intermediate males. The 47% of these females represents 29% of all females—almost exactly the estimate of all females who prefer intermediates.

Intermediate females breed on about the same average date as intermediate males. This is to be expected as a result of the assortative mating. The similar breeding dates of the other females show that the preference for dark males, which are the first to breed, is distributed at random among the female phenotypes, giving rise to sexual selection for the darks without assortative mating.

We thank the Natural Environment Research Council for the financial support for this work and the Computer Syndicate of the University of Cambridge for the use of the IBM 370/165 Computer.

## **Cascading speciation**

CENTRAL to the theory of allopatric speciation is the idea that geographic separation of populations will sufficiently restrict gene flow between them to make possible their genetic divergence1. Wright2 has shown that, at equilibrium, the arrival of one migrant on average every other generation is sufficient to keep a population's genetic composition similar to the source of migrants—at least when selection is not too strong. Wright's result has been extended to one- and two-dimensional arrays by Maruyama3.

There may be some difficulty in describing the usual course of the speciation process in the light of these theoretical results. If one or several dispersing individuals from an established population can reach some location and start a new population, then what is to prevent others arriving from the same source and preventing local differentiation? One possible answer is that speciation depends entirely on infrequent and accidental events. For example, small and large scale geological changes can completely prevent gene flow that was once possible or the 'founder effect'1 could produce rapid enough genetic changes in a newly-founded population that some degree of reproductive isolation could evolve before many more migrants arrive. It is also possible that many species evolve from migrants which have gone sufficiently far from their parent colony that the arrival rate of other migrants from the same colony is far below Wright's limit.

Another mechanism for species formation and one which does not require accidental events is disruptive selection resulting from the ecological conditions in different microhabitats. Experiments have shown that reproductive isolation can sometimes evolve in the presence of gene flow and strong disruptive selection, and theoretical models<sup>6</sup> reinforce that conclusion. Disruptive selection, however, cannot account for the abundance of sibling species or closely related species which are similar in geographic distribution and ecological requirements<sup>1</sup>.

All these factors have been important in evolution, and it is possible that they are sufficient to account for the known rates of speciation. I propose, however, that if the non-equilibrium properties of genetic systems are considered, then the existence of accidental processes or disruptive selection is not necessary for all cases of speciation. In particular, there is often no need to assume that there is some mechanism which 'shuts the door' on future migrants so that speciation may occur.

My argument follows from well known theoretical results. For a diploid species, consider a population of size N which receives m migrant individuals from a second population, and consider a locus segregating for two alleles A and a. Suppose that A is fixed in the second population and a in the first. Then in each generation in which a migrant arrives at the first population, the probability of ultimate fixation (u) of either of the arriving alleles is

$$u = [1 - \exp(-4s)]/[1 - \exp(-4Ns)] \tag{1}$$

where s is the selective advantage of A over a (assuming no dominance and independence of the alleles?). For  $Ns \ll 1$ , u is approximately 1/N and for  $Ns \gg 1$ , approximately 4s. If we assume that each migrant is an independent trial, then the expected time until the arrival of the A allele which will ultimately be fixed is 1/mu. The expected time until fixation of the successful allele must be added to its expected arrival time8. Thus, there is a time lag in the response of a population to gene flow. In this example, if m = 1 and s = 0.01 the time lag until fixation begins (which is a minimum estimate of its importance) is 25 generations. With s = 0.001, the lag increases to 250 generations.

If instead we assume A is increasing deterministically in the second population according to

$$p(t) = \left[ 1 + \frac{(1 - p_0)}{p_0} \exp(-st) \right]$$
 (2)

where  $p_0$  is its initial frequency<sup>4</sup>, then the average number of A alleles carried by each migrant is 2p(t). The probability of ultimate fixation is given approximately by equation (1) so the expected time until fixation of A begins in the first population is

$$\int_0^\infty tump(t) \exp\left[-\int_0^t ump(t)' dt'\right] dt$$

$$= \int_0^\infty \exp\left[-\int_0^t ump(t') dt'\right] dt \tag{3}$$

where the second expression is obtained by integrating by parts. With m = 1,  $p_0 = 0.001$  and s = 0.01, the time lag is 420 generations and with s = 0.001, 4,200 generations. Before A is established another allele serving the same purpose could arise and become fixed. In this way genetic differences could accumulate.

With only two populations, each of which is relatively permanent, the time lag effect may not lead to the evolution of genetic differences, as it requires that new alleles with similar functions arise within a relatively short time. If there were a large number of populations in an array, however, then the time lag would increase roughly linearly with the number of steps separating two populations, and consequently could be significant for populations at opposite ends of the array. The wave of advance of an advantageous allele, which was modelled. by Fisher<sup>9</sup>, would be considerably slowed.

The time-lag effect could also be important when the expected time until extinction of a population is of the same order of magnitude as the time lag. If there were a collection of populations, each of which had some probability of providing the propagules to found new colonies and each of which went extinct at a certain rate, then genetic differences could develop

in different populations as a result of independent mutations in each. The time lag effect would prevent swamping by gene flow between the populations. Such a process could account for the genetic differences between populations of Mus musculus10 taken from a single barn. Those differences would be difficult to explain using an equilibrium theory.

The accumulation of small genetic differences by the combination of the time lag effect and the extinction and colonisation of local populations can be thought of as a cascading process in which the new populations which are founded are likely to be slightly different from the average of the collection of populations. The differences can result both from selection and genetic drift. The accumulation of differences can lead to speciation. I will call this process 'cascading speciation' to distinguish it from speciation processes in which populations are approximately in equilibrium. Cascading speciation skill depends on accidental events, namely extinction and recolonisation, but ecological studies have shown that extinctions and colonisations are relatively frequent events in many species11, and can take place on the same time scale as the time lag associated with gene flow.

If cascading speciation has been an important process, then one consequence is that speciation rates within taxonomic groups with many fugitive species12, which presumably have higher extinction rates and greater dispersal ability, would be higher. If equilibrium processes have been more important, then in such groups speciation rates would be lower because of the higher level of gene flow resulting from the greater dispersal tendencies. One possible example of this is the Drosophila of Hawaii<sup>13</sup> which contains a large number of species and for which there is assumed to be a high rate of extinction of local populations<sup>14</sup>. Carson<sup>14</sup>, in discussing the Hawaiian *Drosophila*, has emphasised the importance of inbreeding in small local populations which would enhance the founder effect and the role of genetic drift; but that does not change the limit on gene flow imposed by the equilibrium theory, which is independent of local effective population size.

In conclusion, I should emphasise that my point is quantitative, not qualitative. Geographical isolation is still necessary for speciation, but if the extinction of local populations is considered, then the degree of isolation necessary is not as great as is often assumed.

I thank Drs M. Kimura, J. F. Crow, T. Maruyama, and T. Ohta for their help during the preparation of this paper.

## Isolation by distance in Liatris cylindracea

Several factors may cause genetic correlation—that is a genetic relationship between individuals within a populationincluding small population size, self-fertilisation, positive assortative mating or isolation by distance. Isolation by distance occurs when gene dispersal is limited so that distant populations in a series or remote areas within a population become genetically differentiated. Under an isolation-bydistance model of genetic differentiation, spatial distance and genetic correlation between individuals or populations are expected to be negatively related, that is, the greater the distance the smaller the genetic correlation. I wish to present evidence for isolation by distance in the plant, Liatris cylindracea Michx. (Compositae), obtained by a genetic distance analysis of gene frequencies at 27 allozyme loci. This analysis revealed genetic differentiation across very small distances and demonstrated that a restriction of gene flow has a profound effect on the spatial distribution of alleles within a population.

Plant species are prime candidates for the study of isolation by distance since they are immobile and gene dispersal in both the pollen and seed phases is often quite restricted. Indeed the earliest study of isolation by distance was on the annual herb Linanthus parryae, which shows genetic differentiation for flower colour. Liatris cylindracea, a prairie gayfeather, is a perennial, obligately outbreeding herb which grows in undisturbed prairies throughout the mid-west of the United States. A single, dense population<sup>2</sup> on a hillside in Zion, Illinois was divided into a grid 18×33 with 3 m<sup>2</sup> quadrats. Up to 60 plants were collected from each quadrat; the collection totalled 2,258 individuals. Starch gel electrophoresis was performed on the plants for 12 different enzyme systems, encoding 27 genetic loci. Gene frequencies were calculated on a per quadrat basis.

Evidence for isolation by distance was provided by analysis of genetic distance within the Zion population. Genetic distance is an index for measuring the accumulated number of gene differences per locus between groups of organisms. Of several available measures of genetic distance I used Nei's because it uses allozyme gene frequency data and, most importantly for a study of isolation by distance, it is related directly to Malecot's coefficient of kinship,  $\varphi$ . Nei's genetic distance is defined as:

$$D = -\log_e(J_{xy}/\sqrt{(J_xJ_y)})$$

where  $J_x$ ,  $J_y$ , and  $J_{xy}$  are the arithmetic means of the probabilities of two randomly chosen genes being identical in populations x, y, and x and y. Genetic distance is expressed as codon differences per locus.

Genetic distance in the L. cylindracea population was calculated for 103 quadrat pairs which had data from all 27

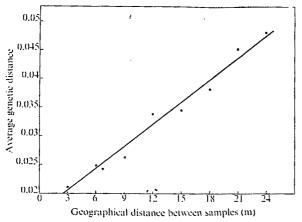

Fig. 1 Genetic distance in L. cylindracea. The genetic distance plotted is the average of all quadrat pairs for a given spatial distance. Geographical distance is the distance (m) between sample quadrats.

allozyme loci. Measurements of genetic distance between sample quadrats showed considerable variation. The mean genetic distance averaged from all of the distances computed is  $0.0396 \pm 0.004$  codon differences per locus. Genetic distance between quadrat pairs ranged from 0.0061 to 0.1156.

Considerable local differentiation within the population is indicated by the genetic distance measures. If genetic differentiation is the result of restricted migration, genetic distance would be expected to be related to spatial distance. The average genetic distance measured between sample quadrats is plotted against spatial distance in Fig. 1. As spatial distance increases between sample quadrats, the genetic distance increases proportionately. This linear relationship of spatial and genetic distance suggests that isolation by distance has occurred in the Zion population.

These results are consistent with the population biology of L. cylindracea. Both phases of gene dispersal, pollen and seed, are very restricted4. Pollen is transferred mainly by bees; field observations on L. cylindracea indicate that most moves by pollinators are to the nearest neighbour. Likewise seed dispersal, although by wind, is limited. This restricted gene dispersal is manifested in the spatial variation of gene frequencies within the population. Statistically significant gene frequency differences of as much as 0.2 existed between neighbouring quadrats. Genetic variation at a single locus, however, generally does not correlate to environmental parameters within the population<sup>2</sup>. Genetic divergence over distance appears to be a function of random gene frequency fluctuations. Only when all loci are considered together does the pattern of genetic variation in the Zion population emerge; genetic distance is positively related to spatial distance. This relationship is as predicted for a population in which gene dispersal is limited and genetic differentiation results from isolation by distance.

# Implications of ethylene production by bacteria for biological balance of soil

ETHYLENE in soil causes fungistasis<sup>1</sup>, affects the growth of bacteria, actinomycetes and nematodes (unpublished data) and consequently must influence many soil biological processes. *Mucor hiemalis* has been proposed as a major producer of ethylene in soil<sup>2</sup> although earlier work suggested that facultative anaerobes may be involved<sup>3</sup>. Our studies show clearly that the main production of ethylene in soil is by spore-forming bacteria in anaerobic microsites. These bacteria seem to be an integral part of a self-regulating cycle in soil controlling microbial activity and with far-reaching implications for the biological balance of soil.

A high organic matter, basaltic soil (Ashburner!), which produces high levels of ethylene, was treated moist for 30 min with aerated steam at 60°, 82° and 100° C to simplify progressively the soil microflora. Samples of treated soil were compared for ethylene production with untreated and autoclaved (60 min at 121° C) samples. Untreated and treated soil samples were dried aseptically at 37° C for 24 h, passed through a 0.2-cm mesh sieve, placed as 5-g lots in four replicate sterile glass vials (14 ml capacity), wetted to 40% water (-0.5 bar water potential) with sterile distilled water, sealed with rubber septa and incubated at 25° C. This is our standardised assess-

ment method. Production of ethylene was reduced significantly only in soil heated above 82° C (Fig. 1). Small quantities of ethylene were detected following treatment at 100° C, but virtually none formed in autoclaved soil. Spore-forming bacteria (both aerobic and anaerobic) were the only significant survivors in soil treated at 60° C and above; some survived the treatment at 100° C, but none survived 121° C. Similar results were obtained with several other soils after treatment with aerated steam. In another test, soil slurries in tubes were heated at 80° C for 1 h in a water bath and then compared for ability to produce ethylene with non-treated slurries when incubated at 25° C. The treatment enhanced ethylene production, especially initially, probably because of heat activation of spores<sup>5</sup>. These results rule out *Mucor hiemalis* as a major producer of ethylene in soil² because it is killed by aerated steam at 60° C or above¹.

In another series of experiments, Ashburner soil was wetted to different water potentials; ethylene was produced at -5 bar and wetter, but only slightly or not at all at -15 bar or drier. Soil bacteria, but not actinomycetes or fungi, are limited by water potentials below -15 bar<sup>6</sup>.

Production of ethylene under aerobic as compared with anaerobic conditions was studied with Ashburner soil wetted to 40% water and incubated at 25° C in the vials under atmospheres of air, nitrogen, argon or hydrogen. The atmospheres in vials of dry soil were evacuated twice and replaced each time with the desired atmosphere. Oxygen-free water was then added by syringe to the soil surface and allowed to move as a wetting front to the bottom of each vial. In all tests, ethylene production was greatest in the absence of oxygen (Fig. 2). A similar result was obtained with a cultivated garden soil (Penrith¹) which normally produced little ethylene. Additionally, ethylene production under a nitrogen atmosphere in Ashburner soil was prevented, or nearly so, by a water potential of—15 bar, confirming the role of anaerobic bacteria.

Amendment of soils with different forms of nitrogen markedly affected ethylene production. Nitrate always delayed production in proportion to the amount added whereas ammonium stimulated production, or had no effect, depending on the soil used. Ethylene production was best in soils leached free of nitrate but if such soils were reamended with nitrate at 20–200 p.p.m. N, production started only after a period of denitrification, or not at all. Nitrate acts as a terminal electron acceptor in the absence of oxygen and can poise the redox potential of soil sufficiently to prevent activity of strict anaerobes<sup>7,8</sup>. This seems to explain how the presence of nitrate prevents ethylene production and indicates that production occurs only under highly reduced conditions in soil.

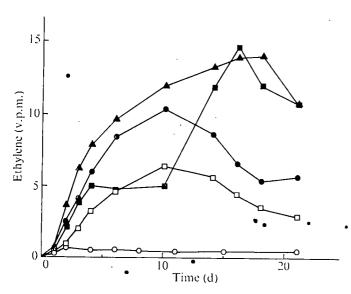

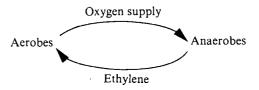

Fig. 1 Ethylene production by Ashburner soil following heat treatment. ♠, Untreated; ♠, aerated steam for 30 min at 60° C; ♠, 82° C; ☐, 100° C; ○, and autoclaved for 60 min at 121° C.

Although ethylene production was best in oxygen-free atmospheres, it was consistently formed, sometimes at high levels, in soil incubated under air and as dry as -5 bar water potential. It was also detected *in situ* at adjacent sites in a soil under mown grass (about 0.5–6.0 p.p.m.) and cultivated (about 0.03–0.5 p.p.m.), including when the soil was considerably drier than field capacity and hence probably well-aerated.

Any apparent conflict in the presence of ethylene in soil under the conditions described and its anaerobic requirements for production, are explained by the occurrence of anaerobic microsites in even well-drained field soil. These anaerobic microsites are continually formed in soil as a result of aerobic microorganisms utilising oxygen especially near organic matter9. Anaerobes will proliferate in these microsites and produce ethylene which diffuses through the soil. Sensitive species of aerobic microorganisms will be inactivated first, but eventually if levels become high enough, most, if .not all, aerobic microbial growth probably will be arrested by the ethylene. The system then becomes self-regulatory because as oxygen demand falls, oxygen will diffuse back into the microsites and prevent anaerobic ethylene production; this will permit resumption of aerobic growth. We also have evidence that the anaerobes depend, at least in part, on aerobes for production of substrate for ethylene formation. This cycle may be summar-

Verification of such a cycle comes from numerous observations made during the glass vial tests on ethylene production in soil. Prolific hyphal growth was observed through the glass vials under a dissecting microscope on the moist soil crumbs when ethylene was low but not when ethylene was high. In tests allowed to continue for over 80 d, ethylene levels reached a peak, dropped, then eventually rose again in cyclic fashion; fungal hyphae appeared, disappeared (lysed) and reappeared in response to the fluctuations. Actinomycetes behaved similarly except that colonies became evident only at intermediate levels of ethylene and after most fungal hyphae had lysed. At high levels of ethylene these colonies also disappeared.

Large inputs of nutrient temporarily override the suppressive effects of ethylene possibly in much the same way fungistasis is annulled by nutrients. Without this means of adjustment, decomposition of organic matter would be slowed, with consequent problems of accumulation in soil.

The concept of an oxygen-ethylene cycle assigns an important microbiological role to the ubiquitous spore-forming anaerobes of soil; by producing ethylene, they prevent microbiologically active soils from becoming predominantly anaerobic. This ensures that the more efficient aerobic respiration dominates the soil system. Anaerobic production of ethylene also explains why ethylene producers do not dominate a soil—anaerobes are prisoners of their microsites.

In our studies, bare cultivated soil has always produced less ethylene than undisturbed or cropped soil regardless of whether measured *in situ* or removed, dried, sieved and tested in the standardised vial test in the laboratory. This has important implications for agriculture because these results indicate that the oxygen-ethylene cycle is in balance in soil under undisturbed ecosystems such as grasslands and forests, where organic matter and plant nutrients are slowly recycled, nitrate nitrogen does not accumulate, and root diseases are rare. Conversion to agricultural usage destroys the balance because tillage aerates the soil, elevates the redox potential and eliminates anaerobic microsites. This increases organic matter breakdown

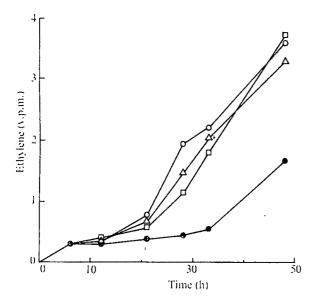

Fig. 2 Ethylene production by Ashburner soil under atmospheres of ●, air; ○, nitrogen; △, argon; □, and hydrogen.

and release of nitrogen. Plants are not present to use the ammonium nitrogen which is rapidly nitrified. Even if oxygenfree microsites redevelop, ethylene production will not resume until nitrate has been removed by plant roots of a subsequent crop, or less desirably, by leaching or denitrification. This seems to explain adequately why cultivation causes an inevitable decline in levels of organic matter, soil structure, and nitrogen availability and an increase in root diseases. Also, the presence of nitrate causes a loss of cations from soil<sup>10</sup> and a paucity of reduced microsites which affects the availability of iron, manganese and phosphorus8.

Precise manipulation of the oxygen-ethylene cycle in soil offers a means of regulating energy turnover and availability of plant nutrients as well as improved control of soil-borne plant pathogens. These results call for a reappraisal of the value of nitrate in agriculture and give new justification for minimum tillage and the use of organic amendments in farming.

## Pigments responsible for ultraviolet patterns in flowers of *Oenothera* (Onagraceae)

Many insect-pollinated flowers have nectar guides1 which increase the foraging and pollination efficiency of their insect visitors2. Some of these are visible only by their contrasting ultraviolet patterns, visible to insects but not to humans3. In such flowers, the nectar guides absorb ultraviolet light, and the compounds responsible were early suspected to be phenolics4. Recently, in Rudbeckia hirta L. (Asteraceae), a mixture of methylated flavonol glycosides has been shown to be responsible5. We report here that another class of flavonoids, chalcones, is responsible for the similar patterns in Oenothera (Fig. 1) and in three other genera of Onagraceae with flowers that appear uniformly yellow to humans.

Fresh petal material of Oenothera hookeri Torr. & Gray ssp. venusta (Bartlett) Munz was divided into ultraviolet-reflective and ultraviolet-absorptive portions. Because these areas cannot be distinguished visually, only small portions of the base and apex of the petal were used to minimise contamination. The material was extracted with methanol for several days to remove visible as well as ultraviolet-absorbing material. Extracts were analysed spectrally and chromatographically.

The absorption spectrum of the extract from the apical reflective portion of the petal had maxima at 460 nm, 435 nm and 415 nm (characteristic of carotenoids), a second maximum at 265 nm (probably non-flavonoid phenolic compounds) and a minimum between 310 nm and 370 nm (Fig. 2A). Extracts from the basal, absorptive portion of the petal had an additional strong maximum at 365 nm (Fig. 2A).

The two-dimensional paper chromatogram of the apical extract indicated that only carotenoid was present. The basal extract contained carotenoid plus an ultraviolet-absorbing pigment which was identified as the chalcone glucoside isosalipurposide<sup>6</sup>. The absorption spectrum of a methanol solution

Fig. 1 Fresh flower of Oenothera grandis in daylight (top) and in ultraviolet light (366 nm) with a Kodak Wratten 18A filter (bottom).

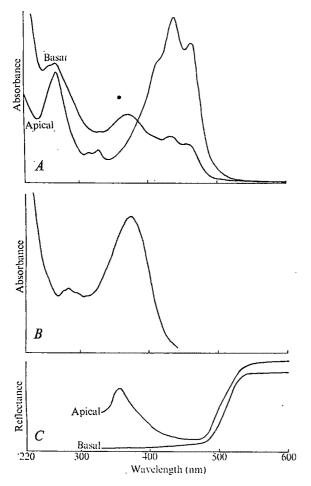

Fig. 2 A, Absorption spectra of methanol extracts of portions of petals from Oenothera hookeri. B, Absorption spectrum of a methanol solution of the chalcone, isosalipurposide. C, Reflectance spectra of portions of a petal of O. hookeri.

of this compound had a single absorption maximum at 365 nm (Fig. 2B). Thus the restricted distribution of the chalcone in the basal portion of the petals results in the observed differences in light reflection. The reflectance spectra of the two portions of the petal (Fig. 2C) also support this conclusion.

The internal anatomy of the petal suggests that the mesophyll is a diffusing and pigmented structure with transparent plates composed of epidermis on both surfaces. Thus much of the light striking a petal is reflected unless it is absorbed by pigment molecules in the mesophyll. In the case of the basal portion of Oenothera petals, the presence of flavonoids absorbing in the near ultraviolet and carotenoids absorbing between 400 and 470 nm results in low reflection of wavelengths 330-480 nm (ultraviolet and blue light) with high reflection in the yellow region of the spectrum giving rise to yellow coloration for both humans and insects. The apical portion of the petal containing only carotenoid reflects ultraviolet as well as yellow light. Thus it appears yellow to humans but bee purple (a combination of ultraviolet and yellow light analogous to human purple which we distinguish when light from both ends of our spectral sensitivities, red and blue, are mixed) to an insect.

The observation of fluorescent patterns under ultraviolet light in pressed herbarium specimens matching the invisible ultraviolet patterns in fresh flowers8 fits this model of petal pigmentation. Flavonoids are stable while carotenoids are liable to autoxidation in air<sup>9,10</sup>. The breakdown products of carotenoids presumably fluoresce under ultraviolet light, whereas the stable flavonoids continue to absorb. Flavonoids commonly appear as dark spots on paper chromatograms illuminated with ultraviolet light.

Other Oenothera species with yellow flowers which absorb

ı

ultraviolet light were examined chromatographically. These represent not only the closely related subgenera Oenothera (O. elata HBK., O. maysillesii Nutt. ex Torr. & Gray) and Raimannia (O. drummondii Hook., O. grandis (Britton) Smith, O. rhombipetala Nutt. ex Torr. & Gray) but also the more distantly related Hartmannia (O. epilobiifolia HBK., O. seifrizii Munz). Results were similar to those for O. hookeri, showing carotenoids present throughout the petal and the chalcone restricted to the absorptive areas. Another group of flavonoids, quercetin derivatives, was found in addition to the chalcone in the basal portions of the petals of all species, although not as abundantly in O. grandis and O. rhombipetala. Myricetin derivatives were also absent from petals of subgenera of Oenothera and Raimannia and present in those of Hartmannia, as reported for their leaves<sup>11,12</sup>. Like the chalcone, myricetin derivatives have absorption maxima in the near ultraviolet.

With the results presented here, two classes of flavonoids, flavonols (in Asteraceae)5 and chalcones (in Onagraceae), have been found associated with absorption of ultraviolet light in nectar guides, indicating that these compounds together with anthocyanins and carotenoids are important in flower pigmentation. The chalcone isosalipurposide plays a role similar to that demonstrated here in Oenothera in other yellow-flowered Onagraceae belonging to the genera Camissonia, Gaura and Ludwigia6.

The involvement of flavonoids in these pigment systems important in plant-pollinator interactions suggests a role for the flavonoids which are ubiquitous in the leaves of angiosperms and contribute to absorption in the ultraviolet portion of the spectrum. Leaves reflect a low level of light with spectral quality such that insects perceive it as grey, a neutral colour3. This means that plants which depend on insect visitors for pollination can advertise their flowers as brightly coloured entities against a dull, neutral background and thus increase the efficiency of their pollinators.

Voucher specimens are deposited in the Dudley Herbarium, Stanford University (DS). This work was supported by grants from the National Institutes of Health and the United States National Science Foundation. We thank Howard Towner for the photographs.

#### Tumbling in pigeons

THE spectacular hereditary trait of backward somersaulting by Tumbler pigeons has been known since 1600 AD1 and was described by Darwin as ". . . one of the most remarkable inherited habits or instincts ever recorded...". The potentially important physiological mechanism of tumbling is unknown, largely because the extreme rapidity of the somersaulting blurs visual observation of the component motions. Filming at 2,000 frames per second the normal flight of Racing Homer pigeons and characteristic tumbling episodes by Parlor (nonflying) Tumbler pigeons, we observed the following. The body position of a pigeon just before and during tumbling is associated with abnormal dorsiflexion of the tail, which occurs within 15 ms after the pigeon is released. Tumbling is synchronised with apparently normal wing movements, propelling the pigeon in only a backward direction, at a rate of 8–10 somersaults per second.

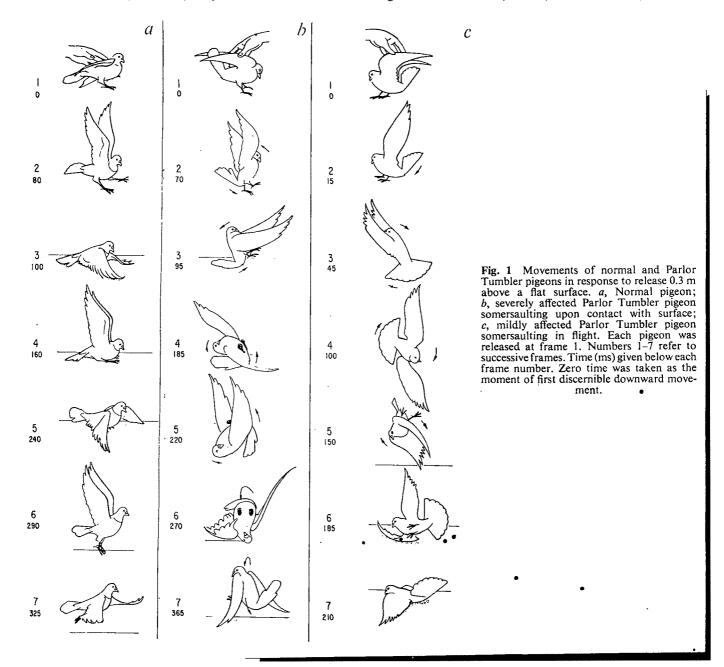

Each filming session involved releasing a hand-held pigeon 0.3 m above a flat surface and activating the camera and high intensity lamps for a period of 1-2 s. Although we were mainly interested in the initial tumbling motions, 5-10 somersaults by each pigeon were filmed during this short time. The film was analysed frame-by-frame and at 16 frames s<sup>-1</sup>. Sketches from representative frames with corresponding times (ms) are shown in Fig. 1.

Figure 1a shows that the normal pigeon raises the wings and extends the feet upon release and lands on the feet with wings forward. In addition, the head, body and tail remain in line

and parallel to the surface below during the descent. Frames 4–7 in Fig. 1a illustrate the initial flying motions, consisting of phasic wing beats accompanied by a forward shift of the body mass that result in flying less than 200 ms later. As in the descent, the head, body and tail remain in line as the pigeon ascends.

Pigeon fanciers and researchers alike use number of somersaults per unit time, duration of a tumbling episode and ease of provocation of tumbling to categorise Tumbler pigeons<sup>3-7</sup>. A severely affected bird will begin somersaulting with each mild provocation such as approaching the bird or snapping the fingers. Less severely affected birds sometimes simply run from the investigator and may somersault only in response to a loud hand clap or to dropping from a height.

The pigeon depicted in Fig. 1b is a severely affected Parlor Tumbler, while that in Fig. 1c represents a milder form. The severely affected Tumbler raises the wings and extends the feet upon release (frames 1 and 2) as does the normal pigeon (Fig. 1a) but the head and body of the Tumbler are not parallel to the surface below. Also the tail of the Tumbler forms an acute angle with the rest of the body. The tail elevation in the Tumbler occurs within 15 ms of release (not shown) and the tail remains in this abnormal position throughout the tumbling episode. The milder form (Fig. 1c) lands with feet and wings extended forward (frame 3) but neither wings nor feet

contact the surface as in the normal pigeon. The abnormal landing appears to be related to the backward angular rotation (nose-up pitching) during descent. Both wings and tail may be involved in the rotatory movement, but we suggest that the tail is the main influence. The initiation of the somersault is seen in Fig. 1b (frame 3) where the pigeon has started to pitch as the wings move forward. Subsequent wing movements appear appropriate for flight, but the abnormal posture maintained during tumbling causes the wing beating to propel the pigeon backwards. A cycle of a single wing beat in the normal pigeon and severely affected Tumbler b lasts 100-125 ms; the head and body remain aligned in both, but the tail is elevated only in the Tumbler. Subsequent somersaults are stereotyped and occur at a rate of 8-10 per second with one wing beat per somersault.

Figure 1b also shows that movements other than pitching rotation occur during tumbling. These are rotation about the longitudinal body axis (rolling) and rotation about a dorsoventral body axis (yawing) which cause the pigeon to land in a position different from that expected after a simple 360° pitching motion. Comparison of frames 3 and 7 in Fig. 1b illustrates the effect of these superimposed motions.

Figure 1c shows tumbling in flight. Wings and feet are again extended and the tail elevated within 15 ms after release (frame 2). After 45 ms descent the pitching motion has positioned the pigeon abnormally but head and body remain aligned (frame 3). The propulsive force for tumbling in flight, as on the ground, is apparently supplied by the wings. The first evidence of tumbling occurs in frame 3 as the forward wing stroke begins; 140 ms later the episode ends in an awkward landing as the cycle is completed (frame 6). Frames 4 and 5 illustrate the rolling and yawing motions, and their influence on the pigeon's ultimate position.

All the Tumbler pigeons we observed had apparently normal wing motions. The force was supplied by the forward wing stroke during which the feathers appeared tightly interlocked. During the back stroke the wing feathers separated and sliced through the air with little resistance. Furthermore, the position of the wings relative to the body was the same in normal and Tumbler pigeons. The feet did not seem to contribute to tumbling; their position varied from one somersault to the next and no pushing movements were observed. In fact, in some cases the feet seemed to decrease the tendency to tumble by exerting a dragging force opposite in direction to the characteristic pitching motion.

The stereotyped abnormality of the Tumbler pigeon possibly arises from the abnormal function of a sensory input, a central or feedback mechanism, or an aspect of the motor output.

The fact that the abnormal response occurs within 15 ms of the pigeon being released is consistent with neural transmission of a stereotyped movement. The inner ears of Tumbler pigeons are normal<sup>6,7</sup>, the cerebella appear normal by light microscopy (R.K.E., and S.H.B., unpublished observation) and earlier experiments indicate that tumbling is not a form of epilepsy<sup>5,6</sup>. In addition, we have recently reported that skeletal muscles of Tumbler pigeons are not myotonic<sup>8-9</sup>. Experiments in progress suggest that tumbling is associated with an abnormality of the central nervous system. Irrespective of the mechanism of tumbling, a better understanding of motor control in animals with prominent basal nuclei might be gained from further studies of Tumbler pigeons.

## Changes in heroin self-administration by a rhesus monkey after morphine immunisation

We have investigated in one primate the effect of immunisation against an opiate on the self-administration of these drugs. Using the rhesus monkey, which will self-administer various drugs, including opiates and psychomotor stimulants1, we have followed the response for heroin before and after immunisation against morphine. Results indicate that antibodies against morphine can block those effects of heroin on the central nervous system (CNS) that maintain self-administration behaviour.

Our procedure was based on existing knowledge of the immune response against opiates. Antibody against morphineprotein conjugates has been demonstrated to bind free opiate hapten2-8. Different antibody specificities have been described when the same immunising opiate was linked to the protein carrier through different positions on the chemical nucleus<sup>3.5-8</sup>. Antiserum obtained after immunisation with morphine-6hemisuccinvl-bovine serum albumin (M-6-HS-BSA), the conjugate we used, has highest and approximately equal affinity for morphine and heroin and progressively less for opioids of decreasing structural similarity.

In vitro studies based on the observation that morphine inhibits electrically stimulated contractions of isolated guinea pig ileum longitudinal muscle have shown that anti-M-6-HS-BSA globulin can block a peripheral pharmacological effect of morphine<sup>9,10</sup>. Concentrated antibody was found to reverse the inhibition of muscle contractions caused by 120 nM morphine in a manner apparently identical to that observed after addition of 10 nM of the narcotic antagonist naloxone11. The drug self-administration model enables extension of these studies to CNS actions of opiates in vivo.

The apparatus used was a modification of that illustrated by Schuster and Johanson<sup>1</sup>. A double lumen polyvinyl chloride catheter was implanted into the right internal jugular vein of a 5.6 kg rhesus monkey and passed subcutaneously to an exit point on the animal's back.

While self-administering drug, the monkey was housed in a wooden cubicle and minimally restrained by a stainless steel harness and attached hollow steel spring arm. The catheter extended from its exit on the monkey's back through the arm, out the back of the cubicle and through a peristaltic infusion pump to connect with a drip bag reservoir of drug solution or saline. The cubicle was sound-attenuated and approximately 75 cm  $\times$  75 cm  $\times$  90 cm. The front door held an observation window, ventilation fan and two boxes, each with a lever and stimulus light. This allowed separate levers and stimulus lights to be associated with heroin and cocaine. A third stimulus light was located high on a side wall.

The monkey was trained to self-administer heroin and cocaine in aqueous solutions of 0.9 % NaCl on a fixed ratio ten schedule (ten presses of the correct lever required for delivery of one infusion). Cocaine, which is not significantly bound by antiM-6-HS-BSA, was used to detect nonspecific changes in drug taking behaviour after immunisation. Such changes could conceivably result from toxic effects of the immunising preparation or from the lack of opportunity to self-administer drug during immunisation, although trained animals after periods of several weeks without access to drugs will readily resume self-administration (unpublished results of C.R.S.). Only one of the two drugs was available each day for a 2-h session, and the sequence of drug availability was varied. The appearance of a stimulus light overhead and another on the appropriate lever signalled the start of each drug session. During all infusions the lever light was turned off and the colour of the overhead light changed. Stimulus lights were controlled and lever presses and infusions taken were recorded by electromechanical programming equipment located in an adjoining room.

Infusion volume was 0.2 ml kg<sup>-1</sup> delivered at approximately 6 ml min<sup>-1</sup>. The heroin dose was 6 μg per kg per infusion, chosen to maintain self-administration behaviour without producing physical dependence that would complicate the two-drug baseline. The number of infusions taken per session for each drug was approximately equated by adjusting the cocaine dose, resulting in 100 µg per kg per infusion of cocaine.

After heroin and cocaine intake had stabilised, substitution

of normal saline demonstrated that the self-administration of heroin and cocaine were independent of each other and that the monkey could detect the absence of either drug in spite of the presence of the usual stimuli associated with drug reinforcement. Two such heroin extinctions and one cocaine extinction observed before beginning immunisation are shown in Fig. 1. The first extinction for each drug showed a rapid drop to zero infusions self-administered per session. The second heroin extinction showed a more typical pattern, an initial increase in responding and number of infusions taken, followed by a drop to an infusion total per session well below the drug baseline but above zero12. When drug solution was reintroduced in each case there was a prompt return to self-administration behaviour. During the saline infusions, intake of the unsubstituted drug varied only within the usual baseline fluctuations. The stability of heroin intake per session throughout this 2-month period also indicates that tolerance was not a significant factor regulating self-administration.

Drug sessions were discontinued and the monkey was transferred to a metal grid cage. He was then immunised subcutaneously with 5 mg M-6-HS-BSA conjugate in complete

Fig. 1 Effect of substitution of saline for drug solutions on selfadministration by a rhesus monkey. Total infusions taken per 2-h session are shown.

Freund's adjuvant. A second 5-mg injection was given 28 d later. Every 2 weeks thereafter 10 mg of the conjugate in incomplete Freund's adjuvant was given. After 20 weeks the serum morphine-binding capacity at 100 pmol ml<sup>-1</sup> <sup>14</sup>C-morphine added was 77,550 pmol ml<sup>-1</sup> undiluted antiserum<sup>8</sup>. Radioimmunoelectrophoresis demonstrated that the morphine was specifically bound to the IgG fraction of serum from the monkey. (We have also found high levels of morphine binding in antisera from two other monkeys immunised with M-6-HS-BSA.)

A catheter was implanted in the left internal jugular vein and the animal, now weighing 6.6 kg, was returned to drug selfadministration. The monkey resumed his former baseline level of cocaine intake but failed to respond for heroin with a frequency significantly above that for saline (Fig. 2). The heroin dose was then successively doubled, allowing a minimum of three heroin sessions per dose. Self-administration was reinitiated at 100 µg per kg per infusion with an average of 16 infusions taken per 2-h session. This is approximately 16 times greater than the original reinforcing dose per infusion and a concentration too depressant in the non-immunised animal to maintain self-administration (R. L. Balster, personal communication). A saline substitution extinction of lever pressing for cocaine was interposed at this time and as before had no appreciable effect on heroin self-administration. The

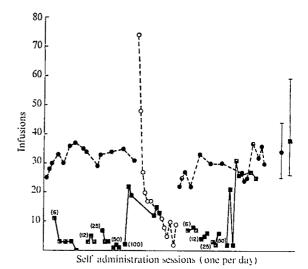

Fig. 2 Effect of immunisation on drug self-administration by a rhesus monkey, and effect of substitution of saline for cocaine after immunisation. Total infusions taken per 2-h session are shown. , Heroin infusions and heroin doses in µg per kg per infusion shown in parentheses; •, cocaine 100 µg per kg per infusion; O, saline infusions with cocaine-associated discriminative stimuli. Mean and range of drug infusions per 2-h session before immunisation are shown.

animal was then returned to the 6 µg kg<sup>-1</sup> heroin dose and the number of infusions taken per session again markedly decreased. In a second ascending series of heroin doses, self-administration was reinstated at 50 µg per kg per infusion with an average of 26 infusions taken per 2-h session (Fig. 2). The increased number of infusions taken by the monkey the second time drug self-administration was reinitiated compensated for the reduced dose at which the reinitiation occurred. As Fig. 3 shows, when heroin self-administration was maintained after immunisation the monkey received approximately 1-2 mg per kg per 2-h session, an amount of heroin about 10 times greater than that necessary to maintain self-administration before immunisation.

During these studies the concentration of antibody decreased. As Fig. 3 shows, serum obtained at least 18 h after the heroin sessions showed a decrease in capacity to bind 14C-morphine from 77,550 pmol ml<sup>-1</sup> undiluted serum\*to 7,900 pmol ml<sup>-1</sup>, approximately 10% of its former level. This decline in antibody available to bind incoming heroin may account for the reinitiation of heroin self-administration at the 50 µg per kg per

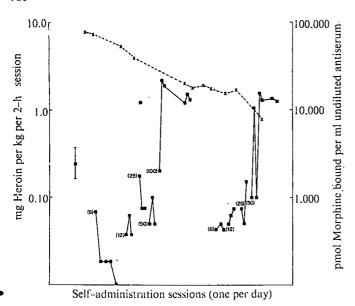

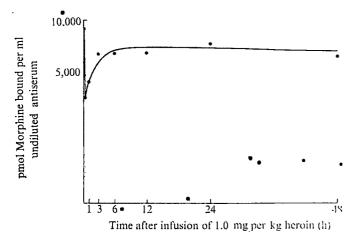

Fig. 3 Heroin intake and serum morphine-binding capacity after immunisation. , Heroin intake. Heroin doses in μg per kg per infusion are shown in parentheses.  $\times$ , Morphine binding capacity. Mean and range of heroin intake before immunisation are shown.

infusion dose in the second series of ascending heroin doses, although a learning effect cannot be ruled out. This decline in antibody concentration also shows that as in other immune reactions opiate antigen is non-immunogenic when bound by antibody in the presence of antibody excess13.

We next studied the time course of the heroin-antibody interaction by giving the monkey a single intravenous infusion of 1.0 mg kg<sup>-1</sup> over 10 min and obtaining frequent serum samples during the next 2 d. The results summarised in Fig. 4 show that the antibody concentration decreased sharply 6 min after heroin infusion. By 3 h it had risen again to approximately three-quarters of the starting concentration and there was little change during the next 48 h. The heterogeneity of antigen-binding we observed is consistent with an earlier finding of both high and very low affinity antibody in M-6-HS-BSA-immunised rabbits14.

Cerebrospinal fluid (CSF) was obtained by lumbar puncture to learn whether the antibody blockade of heroin extended into the CNS. The CSF bound 600 pmol morphine ml<sup>-1</sup> undiluted fluid. The capacity of the serum to bind morphine, determined at the same time, was 10,899 pmol ml<sup>-1</sup>, suggesting that most heroin binding takes place in the peripheral circulation.

The monkey was then allowed to self-administer only cocaine for 2 weeks, during which two booster immunisations were given. Four days after the second booster the monkey stopped

Serum morphine-binding capacity after intravenous infusion of 1.0 mg kg<sup>-1</sup> heroin. Fig. 4

self-administering cocaine. This marked the onset of a febrile illness which ended in the monkey's death 1.5 months later. Autopsy revealed widespread intranuclear inclusions in endothelial tissue supporting a diagnosis of disseminated viral infection. The kidneys showed hypercellular glomeruli with herpesvirus-like inclusions. Electron microscopy revealed intact basement membranes without areas of high electron density. These findings suggest that the monkey's death was not directly related to immunisation with M-6-HS-BSA.

Our results indicate that rhesus monkeys can be induced to produce antibody against opiates. The anti-opiate IgG is present in both serum and CSF. Blockade of CNS actions of heroin by this antibody can be demonstrated. Specifically, those actions of heroin that reinforce its self-administration in the non-dependent rhesus monkey can be blocked. This blockade has been shown to be dose dependent, and it can be overcome by high doses of drug.

## β Alanine and cuticle maturation in Drosophila

THE sclerotisation and tanning of insect cuticles is generally thought to result from a crosslinking of the cuticular proteins by quinonoid derivatives of tyrosine<sup>1,2</sup>. Little consideration has been given to the fact that  $\beta$  alanine is a constitutent of the cuticles of many insects<sup>3,4</sup>, although it is required for normal tanning of the pupal case of several insects. Failure to utilise or produce the compound in Drosophila melanogaster results in an untanned pupal case<sup>5-7</sup>, whereas in Musca domestica, Bombyx mori and Drosophila virilis, failure to incorporate β alanine results in abnormally black cases. In this work, we suggest an explanation for these observations and provide evidence that  $\beta$  alanine also plays a role in the tanning of adult fruit-flies.

Microinjection experiments were carried out as described elsewhere". About 5 nmol of a sterile solution of β alanine (0.1 M) in insect Ringer<sup>8</sup> were injected into the abdomens of pharate adults 0-24 h before eclosion. The microinjection of β alanine into pharate adults of the mutant black produced a striking permanent phenocopy of the normal body colour. Genotypically black organisms injected with insect Ringer developed the typical mutant body colour.

Recently we reported that substantial amounts of dopamine accumulate prior to eclosion in D. melanogaster<sup>9</sup>. Oxidation of this dopamine to indole-5.6-quinone would be expected when O2 becomes available after eclosion, and melanisation would ensue if the indole-5,6-quinone molecules polymerised10. Because melanin deposition over a large part of the adult cuticle of D. melanogaster does not normally occur, we postulated that extensive polymerisation was prevented by  $\beta$  alanine. On this basis, the excessive pigmentation in the mutant black can be accounted for in terms of its failure to produce β alanine<sup>6</sup>. This contention is supported by our observation here that the injection of  $\beta$  alanine into black before eclosion prevents the mutant adult body colour from developing.

A result analogous to that obtained here for black adults has been reported for the black puparium (bp) mutant of Musca domestica. Feeding larvae of this mutant on food supplemented with ß alanine causes a normal (brown) puparium to form. We suggest that in those insects where the potential for abnormal melanisation at pupariation or eclosion exists (as demonstrated by the existence of mutants with excessively melanised cuticles), indole-5,6-quinone in conjunction with  $\beta$  alanine is required for normal tanning. Whether or not indole-5,6-quinone is involved in cuticle maturation at a particular stage in any insect would depend on the extent to which dopamine accumulates at this stage. In D. melanogaster the amount of dopamine present at pupariation is very low, which is consistent with the fact that no mutant of this genus having a dark pupal case is known.

This model readily provides a possible mechanism for the extensive melanisation which does occur in the stripes along the posterior margin of the tergites of wild type D. melanogaster. The obvious correlation between the location of the oenocytes and the pattern of melanin deposition in the abdominal cuticle11 (R.H., and A.C., unpublished) implicates these cells in melanin formation. Extensive indole quinone polymerisation would occur in the cuticle over the oenocytes if these cells did not secrete β alanine. Alternatively, a modification of the cuticular proteins secreted by the oenocytes so that they were unable to bind the indole quinones would also result in extensive melanisation, as experiments on ebony, suggest β alanine is unable to interact with unbound indole quinones to prevent their polymerisation.

Further study is needed on the role of  $\beta$  alanine in cuticle maturation, for we feel that the presently accepted description of tanning and sclerotisation in many insects is incomplete.

#### Spermatozoa motility in human cervical mucus

THE study of spermatozoa penetration and migration into the cervical mucus is of prime importance in the understanding of human reproductive physiology. Cervical mucus is a heterogeneous secretion, the most important constituent of which is a hydrogel made of glycoproteic mucoids<sup>1</sup>. Changes in the arrangement of these glycoproteins seem responsible for the variation in the ability of spermatozoa to penetrate throughout the oestrous cycle. At ovulation or under oestrogenic stimulation, the macromolecules are grouped into parallel micelles which surround spaces containing a fluid of low viscosity<sup>2</sup>. The penetration of spermatozoa into the mucus is entirely dependent on their own motility.

Various tests have been described to study this penetration: the post coital test provides an estimate of the spermatozoa penetration in vivo but only allows a very incomplete appreciation of migration intensity and of movement quality. In vitro tests enable a dynamic study of spermatozoa penetration into the cervical mucus to be made and a simultaneous spermogram provides an estimate of the sperm quality.

When drops of semen and cervical mucus are placed in contact on a microscope slide, the spermatozoa form phalanges at the interface, enter the mucus and then move at random. If, however, the mucus is placed in capillary tubes, an orientated movement of the spermatozoa is observed. In these conditions the migration rate can be evaluated and the corresponding speed ranges from 1.6 to 50  $\mu m$  s  $^{-1}$  (ref. 3).

To obtain a complete, quantitative and objective evaluation of the migration of spermatozoa into cervical mucus, we have developed a method based on the Doppler effect. When an object moving at speed v receives monochromatic light having a frequency vo, it scatters the light which undergoes a frequency change  $v = v_0(2v/c\cos\alpha\sin(\theta/2))$  where  $\theta$  is the angle between the incident beam and the direction in which the scattered light is observed,  $\alpha$  is the angle between v and the exterior bisector of  $\theta$ , and c is the speed of light. For a fixed value of  $\theta$  and when  $\nu$  and  $\alpha$  are single,  $\nu = k\nu \cos \alpha$  has only one value (k being constant). When several objects move at different speeds, but in the same direction (a fixed), the frequency change gives rise to a frequency spectrum S(v). directly representative of N(v); N is the number of objects moving at the speed  $v = v/(k \cos \alpha)$ . When, moreover,  $\alpha$  is unrestricted, the frequency change gives a more complex spectrum; in this case N(v) is represented by the function vdS(v)/dv.

The frequency shift due to the movement of spermatozoa is very small and is detected by a heterodyne technique<sup>4</sup>. The incident light is a He-Ne laser beam; a phototube receives the scattered light from the moving object and a small part of the incident light simultaneously. Beats between these two lights give rise to fluctuations in the photocurrent and the analysis of them (by a Fourier analyser) gives S(v) directly. The cervical mucus is taken with a syringe attached to a pipette made of optical quality glass which acts as a scattering cell. This pipette is 150 mm long of cross section 8 x 3 mm and contains along its axis a central tube 1 mm square. The fine end of the pipette is introduced into the external cervical os and the mucus is aspirated gently. The pipette is then placed for 30 min in a test tube containing 0.3 ml of the sperm to be studied.

To study migration in cervical mucus, the pipette is placed perpendicular to the incident beam which travels through it parallel to the shortest side (e = 3 mm), the scattered light is observed at an angle  $\theta = 8^{\circ}$  so  $\alpha = 4^{\circ}$  and  $\cos \alpha \simeq 1$ . To evaluate motility of the spermatozoa in the semen itself, a flat

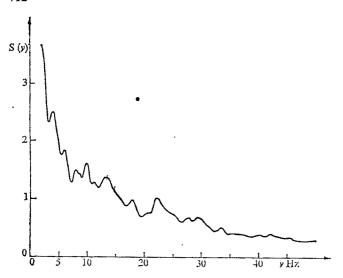

Fig. 1 Frequency spectrum S(v) (arbitrary units) given by the sperm S<sub>1</sub> (60×10<sup>6</sup> spermatozoa ml<sup>-1</sup>; normal motility, 60%; reduced motility: 15%).

cell is used, 15 mm in diameter and having an optical path of 0.1 mm. The plane of the pipette is placed perpendicular to the incident beam, the power of which is less than  $0.1 \times 10^{-3}$  W. The temperature of the cell (pipette or plan cell) is 37° C.

Analysis of the light scattered by the spermatozoa moving in the seminal plasma gives a spectrum S(v) (Fig. 1) which is wide and monotonically decreasing as v increases. The distribution  $N(v_s)$  of instantaneous speed  $v_s$  in the sperm, calculated from this spectrum, is shown in Fig. 2. This wide distribution demonstrates the complexity of spermatozoa movements such as are observed under the microscope when a drop of semen is placed on a lamella.

In constrast, the spectrum representing the movement of spermatozoa in cervical mucus is a remarkably well defined line at a frequency value shifted with respect to  $\nu=0$  (Fig. 3A). This kind of spectrum is unambiguously significant of an

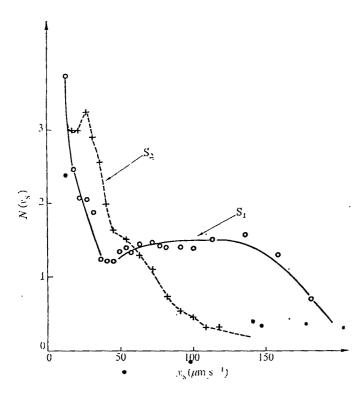

Fig. 2. Velocity distribution  $N(\nu_s)$  (arbitary units) against velocity  $\nu_s$  for sperm  $S_1$  and  $S_2$  (for the sperm  $S_2:94.4\times10^6$  spermatozoa ml<sup>-1</sup>; normal motility: 65%; reduced motility: 5%).

orientated unidirectional movement of the spermatozoa. First of all, this result strongly confirms the spermatozoa migration in cervical mucus observed under the microscope; furthermore, the spectrum gives directly the distribution of the spermatozoa speeds  $V_{\rm M}$  in the mucus, the speed being related to frequency by  ${\rm v}=k\nu$ . By its characteristics (high and well defined speed,  $V_{\rm M}=50\pm10~{\rm \mu m~s^{-1}}$ ), the spectrum in Fig. 3A gives evidence of the good 'mutual' quality of the cervical mucus (orientated structure) and of sperm  ${\rm S}_1$  (high instantaneous speed of the spermatozoa).

The important part played by the sperm quality in the migration through mucus has been pointed out by a complementary experiment. The same mucus as in the previously related experiment has been penetrated by the spermatozoa of another sperm ( $S_2$ ) the means speeds  $\nu_s$  of which, in the seminal plasma, are clearly lower than in the case of the sperm  $S_1$  (Fig. 2). In cervical mucus, movement of the spermatozoa of sperm  $S_2$  gives a spectrum (Fig. 3B) which is very different from that obtained with  $S_1$  (Fig. 3A). The frequency peak is less well defined and remains in very low frequencies: its maximum corresponds to low speed  $V_M$  between 5 to 10  $\mu$ m s<sup>-1</sup>. The relationship between the instantaneous speed  $\nu_s$  in the seminal plasma and

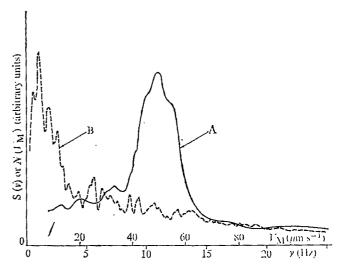

Fig. 3 Frequency spectrum (and velocity distribution) relative to the motion of the spermatozoa in cervical mucus. The measurement has been made 0.5 h after the beginning of the penetration and at 4 cm from the fine end of the pipette. A, sperm  $S_1$ ; B, sperm  $S_2$ .

the migration speed in the mucus is not maintained. In the case of the  $S_1$  spermatozoa,  $V_s$  is 100  $\mu$ m s<sup>-1</sup>, compared with  $V_M$  in cervical mucus, which is 50  $\mu$ m s<sup>-1</sup>. For the  $S_2$  spermatozoa,  $v_S$  is 30  $\mu$ m s<sup>-1</sup>, when  $v_M$  in mucus is approximately estimated as 8  $\mu$ m s<sup>-1</sup>. This indicates the functional importance of the global and objective measurement of spermatozoa velocities in cervical mucus, which points out the importance of the spermatozoa motile quality.

We believe that the scattering light technique related to the Doppler effect gives an excellent tool for the measurement of spermatozoa speeds. Objective velocimetry is of fundamental importance in the study of living motile microorganisms. If the results obtained in the particular cases of sperm S<sub>1</sub> and S<sub>2</sub> are compared by this method and by microscopic observation, the latter test indicates an apparently better quality for sperm S<sub>2</sub> (see Fig. legends) and this estimation, though performed by specialists, is shown to be wrong according to the objective results given by our method. In the case of migration of spermatozoa in cervical mucus, our method provides a total appreciation of the migration with a direct, simple and quick measurement of the speeds. Moreoever, the results confirm that the migration is orientated at the time of

ovulation. Our study corresponds to the first observation by Doppler effect of a type of orientation of living microorganism movement, which is not due to a taxis<sup>5-7</sup> but to mechanical guidance.

## Separation of parathyroid hormone and calcitonin-sensitive cells from non-responsive bone cells

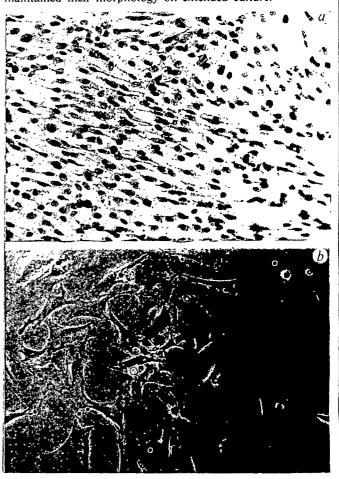

BONE growth and remodelling depend on resorption and deposition at the local level. The balance between these two processes seems to be modulated by the peptide hormones PTH and calcitonin. Parathyroid hormone (PTH) has been shown to induce bone resorption both in vivo1 and in vitro2, whereas calcitonin (CT) inhibits this process<sup>3</sup>. Recent studies suggest that both agents act on cellular mechanisms through a second messenger. Thus, it has been demonstrated that exposure of mouse calvaria to PTH or CT can lead to an increase in cyclic AMP content<sup>4,5</sup>. In addition, dibutyryl cyclic AMP can by itself induce bone resorption<sup>2</sup>.

An understanding of the molecular mechanisms which control synthesis and degradation of bone matrix is lacking. This is a result partly of the complexity of bone tissue in which there exists within the large volume of extracellular matrix a variety of cellular types including osteocytes, osteoblasts, osteoclasts, fibrocytes and marrow elements<sup>6</sup>. Morphological changes suggest that bone cells can respond to both PTH7 and CT8. But, it is not known which of these cells is the primary target for the action of these hormones. Moreover, the fundamental question of whether PTH and CT act on the same or different cell types, is open. Recent efforts to isolate bone cells have resulted in mixtures of cellular types<sup>9,10</sup> which have been used immediately after isolation. Attempts to maintain these cells in culture have resulted in rapid overgrowth by fibroblasts<sup>9</sup>.

A clear elucidation of the molecular events triggered by PTH and CT should be aided by the isolation and identification of the various cellular types. Here we report the isolation of a selected population of bone cells from mouse calvaria which exhibit and retain in culture for several days distinct morphological and biochemical characteristics.

Freshly excised calvaria (usually 25 in number and weighing about 100 mg) were minced and extracted by stirring for 20 min in an isotonic, calcium-free salt solution containing 0.1% collagenase, 0.05% trypsin and 0.005 M EDTA (Table 1). The cells released into the extract were collected by centrifugation at 10,000 r.p.m. for 5 min (population 1). This extraction was repeated a second and a third time to yield cell populations 2 and 3. The yields of cells were  $1 \times 10^6$ ,  $2 \times 10^6$  and  $2 \times 10^6$  in populations 1, 2 and 3 respectively. DNA measurements established that 20% of the total calvarial DNA had been extracted. Samples of calvaria were examined histologically with haematoxylin and eosin and Von Kossa stains after each step of the extraction procedure. There was a high degree of variability in appearance from sample to sample and within the same sample of tissue. The general impression was that the extraction progressively removed cells from the periosteal surface of the calvaria inward such that there was an increasing number of empty lacunae. After the third extraction osteocytes buried in the calcified matrix still remained, as did most of the cartilage and chondrocytes. These remaining cells comprised the bulk of those present in the control samples in agreement with the analyses for DNA.

Cells of each population were placed in monolayer culture at a density of 2×106 cells per culture flask. In addition, the calvarial tissue remaining after the third extraction was also placed in culture. Populations 1, 2 and 3 all exhibited a similar morphology immediately upon isolation. This similarity persisted for up to 48 h in culture and appeared as a mixture of small rounded and stellate cells. After 5-6 d, differences in morphology and growth pattern became evident in the three populations. Population 1 rapidly divided and by 7-10 d spindle shaped cells resembling fibroblasts predominated in the culture (Fig. 1a). The morphology of population 3, in contrast, was transformed into relatively large cells with a highly convoluted dendritic border (Fig. 1b). Cellular division was slow and this morphology persisted for at least 2 weeks. Population 2 at first exhibited morphological characteristics of both populations 1 and 3, but by the 14th day the spindle shaped cells had overgrown the culture. In the case of the cultured calvarial remnants, cells migrated out from the tissue (population 4). Morphologically, these cells resembled closely those of population 3 in their stellate appearance but were somewhat larger. These cells also maintained their morphology on extended culture.

Photographs of bone cells population 1 (a) (fixed and Fig. 1 stained in haematoxylin and eosin) and population 3 (b) 7 days after extraction from mouse calvaria ( $\times$  200).

Calviaria from 2-3-d-old mice were minced and suspended with constant stirring in 5 ml of a sterile salt solution consisting of 136.0 mM NaCl, 2.6 mM KCl, and 0.36 mM NaH<sub>2</sub>PO<sub>4</sub>, containing 0.1% collagenase (180 U mg<sup>-1</sup>, Worthington Crude), 0.05% trypsin (BBL lyophilised powder 2.5%) and 5 mM EDTA, pH 7.0. The cells released into solution after 20 min were collected by centrifugation at 10,000 r.p.m. for 5 min at 20° C (population 1). Fresh enzyme solution was added to the calvarial remains and the procedure was repeated twice to give to cell populations 2 and 3. These were placed in monolayer culture in Minimal Eagles Medium nutrient mixture (Gibco) supplemented with 10% foetal calf serum (Gibco), 100 U ml<sup>-1</sup> penicillin, 100 mg ml<sup>-1</sup> streptomycin and 2.2 mg ml<sup>-1</sup> Na bicarbonate. The calvarial remains were either assayed immediately for hormonal response or were placed in culture to yield population 4. After 7 d in culture, 5 × 10<sup>5</sup> cells from each cell population were inoculated into culture dishes. The standard growth medium was decanted 6 h later and fresh medium containing 5 mM theophylline and PTH (0.44 U ml<sup>-1</sup>) or SCT (0.25 U ml<sup>-1</sup>) was added to the monolayers. The reaction was stopped 5 min later with two rapid rinses in ice cold Tyrode's salt solution. 0.8 ml of ice cold ethanol-0.2 N HCl was added, and the cells were collected by scraping the culture dishes. After 24 h at -10° C the extracts were centrifuged. The supernatants were removed, dried in vacuo, and cyclic AMP measured by the method of Gilman<sup>11</sup>. Protein kinase and protein kinase inhibitor were obtained from Sigma. All determinations were performed in duplicate at two different concentrations of cyclic AMP. Known amounts of cyclic AMP were added to aliquots of each extract as internal standards, and recovery was more than 90%. The pellets were heated in 10% perchloric acid and DNA was measured by Burton's modification of the diphenyl reaction<sup>12</sup>. Each number in the table represents the average ± s.e.m. of 6-8 separate studies.

\*Dif

The four cell populations and fresh unextracted and extracted calvaria were tested for their ability to produce cyclic AMP in response to the bone-active hormones PTH and CT (Table 1). As previously established<sup>4,5</sup>, both hormones rapidly elicited severalfold increases in cyclic AMP content of intact calvaria. The response to PTH was about fourfold greater than to CT at maximally effective concentrations. The effects of the two hormones were additive. After the removal of populations 1-3, however, the calvaria responded only minimally to PTH and not at all to CT suggesting that essentially all of the hormone-sensitive cell populations had been removed by the extraction procedure. Among the cultured isolated bone cells, population 3 exhibited the greatest responsiveness to both PTH and CT. Populations 2 and 4 were substantially less responsive, and population 1 was not responsive. The ratio of the increases in cyclic AMP produced by each hormone was about the same in the responding cell populations as it was in the fresh calvaria. Moreover, the effects of the two hormones were additive.

The action of a few other hormones on the separated cell populations was examined (Table 2). ACTH and MSH had no effect on cyclic AMP levels on the three populations, whereas PTH, CT and adrenaline (which has been reported to affect the level of cyclic AMP in bones<sup>10</sup>) all increased the cellular content of this nucleotide in population 3 and to a smaller extent in population 2. As before, population 1 was unresponsive.

On extended culture, the maximum responsiveness of population 3 to both PTH and CT individually and in combination

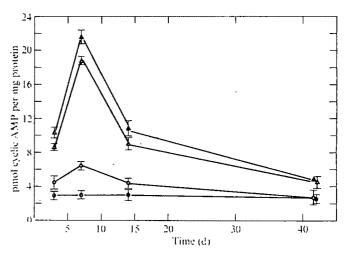

Fig. 2 Loss of response to PTH snd CT upon prolonged culture of population 3. At various times after establishment in culture, 2×10<sup>3</sup> bone cells from population 3 were grown under standard conditions with no additions, (♠); PTH 0.44 U ml<sup>-1</sup>, (△); SCT 0.5 U ml<sup>-1</sup>, (○) or PTH (0.44 U ml<sup>-1</sup>) and SCT (0.5 U ml<sup>-1</sup>), (♠) in media supplemented with 5 mM theophylline. After 3 min the reaction was stopped by rapid rinsing of the cells with ice cold Tyrode's salt solution. The cells were then processed for cyclic AMP measurements as described in Table 1. Protein was measured by the method of Lowry et al.<sup>13</sup>. The bars for each data point represent: s.e.m.

Table 2 Specificity of hormonal response

Specificity of hormonal response. Seven days after establishment in culture, bone cell populations 1, 2, 3 and 4 were subcultured in 5 mM theophylline and PTH (0.44 U ml<sup>-1</sup>), ACTH (0.35 U ml<sup>-1</sup>), MSH ( $10^{-8}$  M), SCT (0.5 U ml<sup>-1</sup>) or L-adrenaline (8 ×  $10^{-6}$  M) was added for 10 min. The control nedium contained only theophylline. The reaction was stopped by the addition of ice cold Tyrode's salt solution. Cells were rinsed and processed for cyclic AMP measurement as described in Table 1. MSH was a gift from Dr J. Pawalek, and ACTH and L-adrenaline were purchased from Sigma.

\* Differs significantly from control P < 0.01

<sup>†</sup> Differs significantly from control P < 0.01

reached a peak at 7 d and then declined (Fig. 2). After 40 d the response to PTH was slight and that to CT was not detectable. Peak responsiveness occurred at the time when the distinctive morphology illustrated here (Fig. 1b) was well established.

These results indicate that a selected population of bone cells may be obtained by sequential extraction which seem to be specific targets for PTH and CT. To our knowledge this is the first time that such a separation has been demonstrated.

The present data which show an additive effect of PTH and CT on cyclic AMP levels suggest that non-competing receptor sites for both hormones are present in population 3. The coextraction of PTH and CT-responsive cells (Table 1), the simultaneous peaking of the responses at one week in culture (Fig. 2), and the simultaneous loss of this responsiveness on extended culture (Fig. 2) suggest that the receptors to PTH and CT reside either in the same cell, or in different cells which exhibit a similarity in their extractability from bone and viability in culture. Efforts are under way to further fractionate the cells in population 3 (on the assumption that this is a heterogeneous population), and to investigate some of the molecular events initiated by these hormones.

## Presence of a gonadotrophin on the surface of preimplanted mouse embryos

In humans, a gonadotrophin (hCG) is localised on the cell membrane of the syncytiotrophoblast facing the maternal bloodstream<sup>1</sup>. The syncytiotrophoblast is derived from the trophoblast cells of the mammalian blastocyst and is thought to participate in isolating the foetus from attack by the maternal immunological system<sup>2</sup>. Martin, et al. suggest that the hCG on human syncytial plasma membranes may, in part, be responsible for the lack of maternal immunological rejection of the foetus; in addition to its role in steroidogenesis, therefore, hCG may also have an immunological function during pregnancy. Because hCG is generally used to induce super-ovulation in mice and must, therefore, cross-react with mouse gonadotrophin, and since the mouse is extensively used in studies on mammalian development, I investigated the possible presence of gonadotrophin(s) in mouse embryos before implantation and formation of the syncytiotrophoblast. Using an antiserum to hCG and indirect immunofluorescence (IIF) I have detected a luteinising hormone (LH)- or hCG-like substance ('embryonic gonadotrophin', EG) on the cell surfaces, of live mouse preimplanted embryos.

Random-bred SWR female mice 6-8 weeks old were superovulated and mated to provide unfertilised eggs and various in vivo preimplantation stages for the IIF assays3. Superovulated BALB/c females mated with C57BL males, and naturally-ovulated ICR female mice mated with C3H males, provided additional in vivo morulae and blastocysts. Two-cell embryos from super-ovulated SWR mice were collected and cultured to blastocysts, using standard techniques4.5, to provide in vitro preimplantation stages. Blastocysts which had been collected from SWR mice and allowed to attach to, and grow on, glass slides were also examined. The IIF assay consisted of a 30-min incubation in rabbit anti-hCG (Miles Laboratories) diluted 1:1 with phosphate buffered saline (PBS), two 5-min rinses in culture medium, a 10-min incubation in goat antirabbit IgG conjugated with fluorescein (Antibodies, Inc.) diluted 1:4 with PBS, and two 5-min rinses in culture media to remove unbound conjugate. Slides of fixed mouse placenta (16-18 d), human second-trimester placenta, and mouse ovary were assayed for IIF-detectable gonadotrophin using anti-hCG and anti-rabbit IgG fluorescein conjugate as previously described. IIF controls were incubated in either normal rabbit serum followed by flourescein, or in the fluorescein conjugate only. Most of the stages were assayed in triplicate. Embryos were placed in a small amount of culture medium on glass slides, and the slides of tissue sections were viewed with a Zeiss fluorescence microscope and photographed using Agfa GAF 500 colour slide film (exposures of 1 min).

Before the eight-cell stage, little gonadotrophin was detected on the cell surface on any of the stages (Fig. 1). Then, only a few isolated blastomeres of an occasional embryo would show light fluorescent outlines. Cell surfaces of morulae, however, were strongly positive for gonadotrophin and remained positive as blastocoel formation ensued. With blastocyst expansion. however, fluorescence diminished to pre-morulae levels and was not detectable on blastocysts which had attached to, and grown on, glass. Results for embryos cultured from the two-cell stage were similar except that the marked increase in positive fluorescence observed with the morulae was depressed slightly and persisted throughout blastocyst hatching. No consistent differences in the pattern of positive fluorescence was observed between embryos taken from naturally or super-ovulated mice,

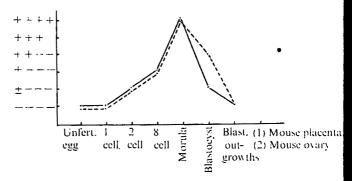

Fig. 1 Cell-surface gonadotrophin detected by IIF on mouse preimplantation embryos. The impressions of three observers who scored the embryos for positive fluorescence were averaged to produce the differences in fluorescence assigned to the preimplantation stages. The symbols (--) and (++represent the total lack, and the greatest amount, respectively, of IIF-detected cell-surface gonadotrophin. Gradual replacement of plus signs with minus signs indicate diminishing levels of fluorescence. In vivo embryos, -; cultured embryos,

or from mice of different strains. No anti-hCG binding was observed on mouse 16-18 d gestation placenta, or mouse ovary. Positive fluorescence was observed on sections of human second-trimester placenta, and was confined to the syncytiotrophoblast of the chorionic villi.

Existing opinion holds that production of EG (gonadotrophin secreted by the placenta or its derivatives) is confined to the syncytiotrophoblast. The rabbit blastocyst has, however, been shown to contain a gonadotrophin which competes with hCG in binding assays<sup>7</sup>, and to secrete an LH-like substance by radioimmunoassay<sup>8</sup>. These observations, together with the high maternal plasma levels of hCG observed at about the time of implantation<sup>9</sup>, indicate that EG may be produced before implantation and formation of a syncytium. The observation that anti-hCG binds to morulae cultured from two-cell embryos suggests that, in addition to having a trophic hormone(s) on their cell surfaces (irrespective of the origin of the hormone), mouse preimplantation embryos may synthesise at least some of the gonadotrophin found on their surfaces.

Besides initiating steroidgenesis, cell-bound gonadotrophins may play a role in mediating protection of the conceptus against maternal rejection during implantation. Such a role has been suggested for hCG, which reversibly inhibits PHAstimulation of human lymphocytes in vitro 10 and is found in high concentrations in plasma throughout pregnancy. It is not known whether EG has a similar role in rodents nor whether chorionic gonadotrophin is present in rodents, including the mouse (A. Contopoulos, personal communication). No antihCG binding was detected on blastocyst outgrowths, nor on mouse placenta, whereas human placenta similarly fixed and assayed was positive for anti-hCG binding. Perhaps a gonadotrophin is present in mouse placenta, but in a form not recognised by anti-hCG.

It is now widely thought that polypeptide hormones achieve their effects by first interacting with the cell membrane or with membrane-bound enzymes11. hCG binds to the cell membranes of luteinised rat ovaries and presumably such binding precedes the onset of ovarian steroidogenesis<sup>12</sup>. Initiation of steroidgenesis found in the preimplantation embryos of the rat13 and rabbit14 may also require the presence of cell surface-bound gonadotrophin. In addition, it has been suggested that steroidgenesis in the preimplanted rat embryo may be necessary for morulae to blastocyst transformation<sup>13</sup>. Similar processes may also occur in the mouse.

In conclusion, mouse preimplantation embryos display a gonadotrophin(s) on their cell surfaces, and IIF-detectable levels of this gonadotrophin(s) is maximal on morulae. In addition, I suggest that the preimplanted mouse embryo may be capable of synthesising at least some of the gonadotrophin found on their surfaces.

I thank Drs Patricia G. Calarco, Laurel E. Glass and Charles J. Epstein for assistance in preparing the manuscript, and Alex Kofinas for technical assistance. This work was supported by funds from the United States Public Health Service and the Department of Anatomy.

### 1,25-dihydroxycholecalciferol-like activity of Solanum malacoxylon extract on calcium transport

CATTLE grazing the South American egg plant, Solanum malacoxylon, develop hypercalcaemia and hyperphosphataemia resulting in severe calcinosis1. The active principle in the plant stimulates intestinal calcium transport2-4 and bone mineral resorption<sup>2,4</sup> in laboratory animals. It resembles vitamin D except that it is water soluble1.5 and exerts its initial action and declines in activity more rapidly2. Recent work6 suggests that the factor closely resembles 1,25-dihydroxycholecalciferol (1,25-(OH)<sub>2</sub>-D<sub>3</sub>), a metabolite of vitamin D<sub>3</sub> formed in the kidney<sup>7</sup>, in that it overcomes the inhibition by dietary strontium<sup>8</sup> of vitamin D<sub>3</sub>-induction of the intestinal calcium-binding protein (CaBP) and, concomitantly, calcium absorption9.

Here we demonstrate that the S. malacoxylon factor stimulates the calcium absorptive mechanism of the organ-cultured chick duodenum, indicating that the activity of the factor does not depend on preliminary metabolism by some other tissue, that, indeed, it resembles 1,25-(OH)2-D3 in terms of its biopotency, and that its mechanism of action, like that of both vitamin D<sub>3</sub> itself and 1,25-(OH)<sub>2</sub>-D<sub>3</sub>, is dependent on intestinal protein

Technical details of the organ-culture system, assay of CaBP and measurement of calcium uptake and transport in the cultured duodenum have been published elsewhere 10-12.

After preliminary experiments proved that S. malacoxylon extract (Fig. 1 legend) was effective in eliciting vitamin D-like responses in organ-cultured duodena, a time study was conducted (Fig. 1). Within 12 h of culture, the extract induced CaBP synthesis and stimulated 45Ca uptake. There was excellent correlation between CaBP concentration in the tissue and the ability of the tissue to accumulate radiocalcium. This experiment confirmed the vitamin D-like activity of the Solanum factor as only vitamin D<sub>3</sub>, and related sterols<sup>10-13</sup>, are effective in inducing CaBP in this system. The lag time observed was more reminiscent of vitamin D<sub>3</sub> itself (which is effective without transformation in this system<sup>11</sup>) than 1,25-(OH)<sub>2</sub>-D<sub>3</sub> (refs 10 and 13). There is, however, ample evidence (for example, its water solubility<sup>1,5</sup>) that the active principle in S. malacoxylon is not a simple sterol (Peterlik and R.H.W., unpublished). The possibility exists, therefore, that some preliminary transformation of the principle must take place before its characteristic activity ensues but our results indicate that such change can occur in the intestine itself.

Other evidence supports the contention that the Solanum factor is more like 1,25-(OH)2-D3 than vitamin D3. The doseresponse relationship for Solanum extract was compared with that of authentic 1,25-(OH)2-D3, by far, the most potent sterol for CaBP induction in this system<sup>10,11</sup>. In terms of CaBPinducing potency, 0.01 and 0.1% concentrations of Solanum extract were equipotent to 65 and 650 pM 1,25-(OH)<sub>2</sub>-D<sub>3</sub>, respectively (Table 1). This means that there were 650 pmol of 1,25-(OH)2-D3-like activity in each ml of Solanum extract, or 365 pmol of 1,25-(OH)<sub>2</sub>-D<sub>3</sub>-like activity per g of powdered leaf.

Another experiment confirmed the 1,25-(OH)<sub>2</sub>-D<sub>3</sub>-like

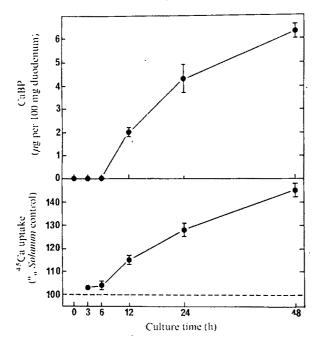

Fig. 1 Time study of the effect of S. malacoxylon extract (0.1% of the culture medium) on CaBP synthesis and stimulation 6 of the culture medium) on CaBP synthesis and stimulation of \*\*Ca uptake. Values are the mean ± s.e. The S. malacoxylon extract used in these experiments was prepared by shaking the dried, ground leaf three times with three volumes of methanol: chloroform (2:1) for 2 h at room temperature discarding the solvent each time. After residual solvent removal by aeration, the residue was shaken with nine volumes of water for 16 h The aqueous extract was filtered through cheese-cloth and centrifuged (24,000g for 20 min). The supernatant was lyophilised, shaken for 16 h in 75% ethanol in water and centrifuged. The ethanolic extract was concentrated sixfold and stored at -20° C. This procedure effected a 42-fold concentration of the active principle over the powdered leaf. Activity of the various fractions was assayed by determining CaBP production when administered to rachitic chicks 4 weeks old18. Aliquots of this final concentrated extract were added to the culture medium as indicated. Duodena were cultured slit-open on grids<sup>10,11,13</sup> mucosal-side-up for the times indicated, in the presence of either the extract or extracting solvent alone (75%) EtOH-control group) in the culture medium. CaBP assay and <sup>45</sup>Ca uptake were performed as previously described<sup>10,13</sup>. There was no CaBP present in duodena cultured in the presence of extracting solvent alone.

activity of the Solanum factor in what has proven to be a new test system, that is, the embryonic chick duodenum in ovo. Some time ago, it was found that embryonic chick duodenum neither contains CaBP until the day of hatching (day 21) nor synthesises CaBP in response to the injection of vitamin D<sub>3</sub> directly into the egg14. Recent work has confirmed this original observation while demonstrating that metabolism of vitamin D<sub>3</sub> to its more active metabolites does occur in the embryo15. We here report that injection of 1,25-(OH)<sub>2</sub>-D<sub>3</sub> (300 pmol per egg) directly into the egg (at 18 d incubation) did induce precocious CaBP synthesis when measured 36 h after injection  $(8.3 \pm 0.9 \mu g \text{ CaBP per } 100 \text{ mg duodenum})$ . Interestingly, when Solanum extract was injected into each egg (an amount estimated to contain 325 pmol 1,25-(OH)2-D3-like activity; see Table 1), CaBP was also induced and to an almost theoretically predictable extent (8.9  $\pm$  1.7  $\mu g$  CaBP per 100  $\,$  mg duodenum). By contrast, 240,000 pmol vitamin D<sub>3</sub> (800 times as much 1,25-(OH)2-D3 on a molar basis) was completely without effect and 26,000 pmol 25-OH-D<sub>3</sub> was only marginally effective (3.2  $\pm$  0.6  $\mu g$  CaBP per 100 mg duodenum). The . embryonic chick duodenum is refractory to endogenous levels of vitamin D<sub>3</sub> and its metabolites, although possessing the inherent ability to respond to sufficient levels of these sterols both in organ culture<sup>10-13</sup> and, to the active metabolites, in ovo. This strongly suggests that stimulatory levels of the appropriate sterol are not reached in the duodenum in ovo. The reason for this is completely unknown.

The action of either vitamin D<sub>3</sub> (refs 12 and 13) or 1,25-(OH)<sub>2</sub>-D<sub>3</sub> (ref. 16) in the organ cultured duodenum has been shown to be an actinomycin D-sensitive process, that is, sterol action involves DNA transcription and subsequent protein synthesis. The Solanum factor seems to act by a similar mechanism as actinomycin D completely abolished the response to Solanum extract (Table 2). It is also interesting to note that not only 45Ca uptake by the duodenum, but also mucosal-toserosal transport were stimulated by Solanum and that both <sup>45</sup>Ca movements were inhibited by actinomycin D.

The foregoing experiments confirm and amplify previous work<sup>6</sup> indicating the 1,25-(OH)<sub>2</sub>-D<sub>3</sub>-like activity of the Solanum factor. There is no doubt that this factor functions by an actinomycin D-sensitive mechanism, similar to that of the D-vitamins, in inducing CaBP and stimulating calcium transport. There also can be little doubt that, with respect to its biopotency in culture and in ovo, the factor in S. malacoxylon extract resembles 1,25-(OH)<sub>2</sub>-D<sub>3</sub>. The recent report that aqueous extracts of Solanum failed to mobilise bone calcium in vitamin D-deficient rats fed a low calcium diet, while 1,25-(OH)<sub>2</sub>D<sub>3</sub> was effective<sup>17</sup>, is hard to reconcile with the present findings, those with strontium-fed chicks6, and those of earlier workers who did, in fact, show an action on bone mineral resorption<sup>2,4</sup>.

lative potency of S. malacoxylon 1,25-(OH)<sub>2</sub>-D<sub>3</sub> in the induction of CaBP extract and Relative Table 1

Values are mean ± s.e. Duodena were cultured slit-open on grids10. 11.13 mucosal-side-up for 48 h in the presence of the extract (prepared as given in the legend to Fig. 1) or the authentic sterol in the culture medium. Additions were made in EtOH such that the final EtOH concentration was 0.1%. CaBP assay was performed as previously described 10-13.

Finally, the active principle from Solanum malacoxylon, or, perhaps, from some abundant native plant, holds promise as an source of 1,25-(OH)2-D3-like activity. This may prove important given the difficulty and expense of producing synthetic 1,25-(OH)2-D3 and the widespread desirability of utilising 1,25-(OH)2-D3 for studies of animal and human disorders of calcium metabolism which may be refractory to vitamin D. itself. Isolation and purification of the active principle is of great importance and is proceeding in several laboratories. In our own laboratory, the organ culture system—and the in ova

#### Malaria and the permeability of the host erythrocyte

WHEN an animal is infected with malaria some of the properties of the membrane of its erythrocytes are changed1. The fragility is increased2-6 and the transport of sodium, potassium and amino acids across the membrane is altered<sup>6-10</sup>. In most cases these alterations have been shown to be present in all erythrocytes from an infected animal and not just those containing parasites, which suggests a general pathological effect rather than a direct action of the parasite on its host cell.

We have found that erythrocytes from infected animals also show an increased permeability to L-glucose, a substance which does not readily penetrate either the membrane of erythrocytes from normal animals or that of immature red cells. This increased permeability could be related to the other membrane changes described above, and if so should be shown by both parasitised and non-parasitised erythrocytes from an infected animal. The complete separation of these two types of cell would be difficult, but an approximate separation can be made by centrifugation<sup>5,6,8</sup>, since those cells which contain parasites sediment more slowly than those which do not. We have therefore used this technique to determine whether all cells or only parasitised cells show an increased permeability to L-

Blood from 10-15 mice infected with Plasmodium berghei (a malarial parasite of rodents) was pooled, the white cells removed and the erythrocytes collected by centrifugation after washing three times with buffer medium (pH 7.35). Approximately the upper and lower quarters of the packed cells were removed, each resuspended in buffer medium containing L-1-14Cglucose, and centrifuged after 3 min. Radioactivity in cells and buffer medium was then measured in a liquid scintillation counter. Details of the materials and general methods used will be published elsewhere (K.D. Neame and C.A. Homewood, unpublished). The possibility that the pooled blood contained erythrocytes from uninfected or poorly infected animals was avoided by examining blood from each animal, and rejecting any animals in which the percentage of erythrocytes parasitised was particularly low for the group.

The uptake of the labelled L-glucose by the erythrocytes is shown in Fig. 1. Uptake has been expressed in terms of the distribution space in the centrifuged packed cells, which included residual buffer medium. The inulin space of packed erythrocytes is therefore also given, and the L-glucose space of erythrocytes from normal animals is included in the figure for comparison. It can be seen that the parasite-rich fraction of cells (top layer of packed cells) showed a consistently higher L-glucose space than did the parasite-poor fraction (bottom layer), and that the size of the L-glucose space was proportional to the percentage of erythrocytes which were parasitised.

These findings strongly suggest that only those cells which contain parasites become readily permeable to L-glucose, and that the change in permeability thus appears to be a direct effect of the parasite on the cell in which it is contained, and is not merely a generalised effect on all erythrocytes. This is supported by the further finding that incubation (at 37° C for 1 h) of normal erythrocytes with plasma from infected mice had no effect on their subsequent permeability to L-glucose.

This increase in the permeability of the parasitised erythrocyte may be a striking example of the means by which a parasite, in addition to adapting itself to the host, might also adapt the host cell to its own requirements by allowing the entry into the erythrocyte of certain nutrients normally excluded from the cell.

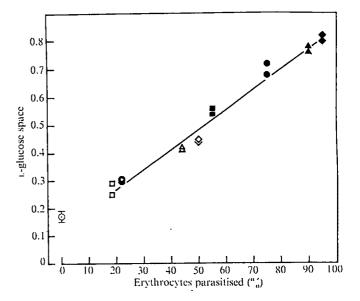

Fig. 1 Relationship between uptake of L-glucose by erythrocytes and percentage of erythrocytes parasitised. Erythrocytes from mice infected with P. berghei were fractionated as described in the text. Each group of four symbols of similar shape gives values from a single pooled sample of blood; the upper pair (closed symbols) represent duplicate samples from the top layer of centrifuged cells, and the lower pair (open symbols) represent duplicate samples from the bottom layer. Inulin space of packed cells: normal mice,  $0.14 \pm 0.02$  s.d., n = 6; mice with about half the erythrocytes parasitised,  $0.19 \pm 0.02$  s.d., n = 8.  $\odot$ , L-glucose space of erythrocytes from uninfected mice (mean  $\pm$ s.d., n = 6).

We thank the Division of Malaria and other Parasitic Diseases, World Health Organization, for partial support of this work, and Miss E. M. Atkinson for technical assistance.

#### Tyrosine-dependent increase of tyrosine hydroxylase in neuroblastoma cells

Tyrosine hydroxylase (tyrosine-3-monooxygenase), presumably the rate-limiting enzyme in the biosynthesis of the adrenergic transmitters dopamine and noradrenaline<sup>1,2</sup>, catalyses the hydroxylation of both phenylalanine and tyrosine3.4. This property has been exploited for the selection of adrenergic-like mouse neuroblastoma cells5, which have high tyrosine hydroxylase activity and can grow in the absence of tyrosine because they can convert sufficient phenylalanine to tyrosine for cell growth. N1E-115 is such a neuroblastoma clone<sup>5,6</sup> and we have now found that, when the amount of tyrosine in the medium is increased, there is an increase in the amount of tyrosine hydroxylase in N1E-115 cells. Modification of the amount of this ratelimiting enzyme by its substrate concentration may play a fundamental role in the regulation of the biosynthesis of catecholamines.

NIE-115 cells (provided by Dr Marshall Nirenberg) were grown as monolayer cultures in polystyrene Petri dishes, 150 mm in diameter (Falcon), at 37° C in a humidified atmosphere of 10% CO<sub>2</sub> and 90% air. Cells were grown as before in the Dulbecco-Vogt modification of Eagle's medium (DNEM, Gibco, catalogue No. H-21) containing 4.5 g of dextrose per litre, 0.42 mM tyrosine and phenylalanine, no Na pyruvate and 5% foetal calf serum. Cells were maintained in stationary phase for approximately 1 week and fed a mixture of 3 parts F-14 medium8 and 1 part DMEM which contained a final concentration of 0.16 mM tyrosine and 0.21 mM phenylalanine. During experimental procedures, cells were maintained in F-14 medium containing 0.12 mM phenylalanine, various concentrations of tyrosine and 2% dialysed foetal calf serum. After experimental incubations monolayers were washed three times with an isotonic salt solution and cells were collected by scraping and washing with approximately 1 ml of 0.05 M potassium phosphate buffer (pH 6.8) containing 8% sucrose. The recovered suspension was sonicated and centrifuged at 30,000g for 30 min. The clear extract that we used contained more than 90% of the total tyrosine hydroxylase activity. Tyrosine hydroxylase activity was measured by the tritium release method9. The standard assay was carried out in 0.50 ml that contained: 50 µmol potassium phosphate (final pH 6.1); 25 nmol L-tyrosine containing 800,000 c.p.m. of 3,5-3H-L-tyrosine (original specific

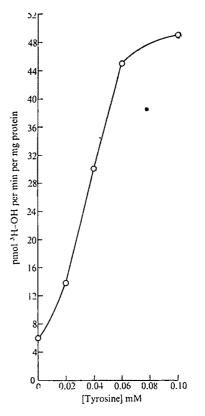

Fig. 1 Effect of increasing levels of tyrosine in the culture media on tyrosine hydroxylase activity in N1E-115 neuroblastoma cell extracts.

activity 1.0 Ci mmol<sup>-1</sup>) (Amersham-Searle) purified before use<sup>10</sup>. 20 μmol β-mercaptoethanol, 2,000 U catalase (Boehringer-Mannheim), 0.50 µmol 6-methyltetrahydropterin (Calbiochem) and the tyrosine hydroxylase-containing extract to be assayed (0.3-0.7 mg protein per assay). Incubations were carried out at  $37^{\circ}$  C for 10 min and stopped with 0.5 ml of 10% trichloroacetic acid. Protein was determined by the method of Lowry et al. with bovine serum albumin as a standard11. The tyrosine hydroxylase activity from this cell line has been reported to be higher than the activity described here12. Several variables may account for this difference, for example: (1) previous use of 10% undialysed foetal calf serum, (2) growth of cells to a greater degree of differentiation before and (3) use of 500  $\mu M$  tyrosine in the earlier assay system compared with the use of 50  $\mu M$  tyrosine in the present assay system. Specific tyrosine hydroxylase antiserum was produced in sheep as before<sup>13</sup>. A crude γ-globulin fraction was obtained by fractionating control and immune sera by the addition of saturated ammonium sulphate at pH 6.8 until 25% saturation was achieved. The pellet was collected by centrifugation and resuspended in the original volume of serum with 0.02 M potassium phosphate and 0.3 M glycine buffer, pH 6.8. The 0-25% ammonium sulphate fractionation was repeated and the second pellet was suspended in the same volume of phosphate-glycine buffer.

When N1E-115 cells were incubated for 24 h in media containing tyrosine, the activity of tyrosine hydroxylase increased eightfold as tyrosine concentration increased from 0 to 0.10 mM (Fig. 1). In other experiments (not shown) the increase in tyrosine hydroxylase activity levelled off at concentrations of 0.10-0.30 mM tyrosine. Results were similar with another adrenergic-like neuroblastoma cell line N-TD65. During the 24 h exposures to various concentrations of tyrosine, total cellular protein per dish did not vary more than 15%. Total and specific tyrosine hydroxylase activity in cells maintained without tyrosine for 24 h and then exposed to 0.10 mM tyrosine for 0, 1, 4, 9, 13 and 24 h, increased in a time-dependent manner (Fig. 2). After 24 h this enzyme activity had increased threefold. It is not apparent why a larger increase was not observed.

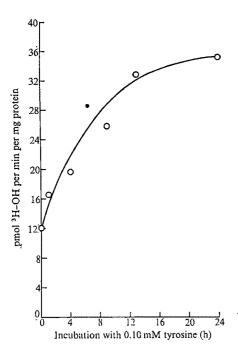

Fig. 2 Increase in tyrosine hydroxylase activity in N1E-115 neuroblastoma cell extracts as a function of time of incubation in media containing 0.10 mM tyrosine. The cells were first maintained for 24 h in F-14 medium containing 0.12 mM phenylalanine, 2% dialysed foetal calf serum and no tyrosine. During the experiment the cells were maintained in the same medium with 0.10 mM tyrosine.

The increase in tyrosine hydroxylase activity in response to tyrosine in the medium could have been due to the synthesis of new enzyme molecules, or the activation of existing enzyme molecules. We have investigated this question by titrating N1E-115 extracts with specific anti-tyrosine hydroxylase  $\gamma$ -globulin. Some results are presented in Fig. 3, which show that inhibition of the higher level of tyrosine hydroxylase activity required proportionally more antibody. Extrapolation of the titration data to the abscissa gives equivalance points which indicate that 1.66 times as much antibody would be required to inhibit totally tyrosine hydroxylase activity of cells grown in 0.10 mM tyrosine as of those grown in 0.04 mM tyrosine.

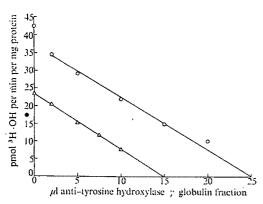

Fig. 3 Titration of tyrosine hydroxylase activity from N1E-115 neuroblastoma cell extracts with specific anti-tyrosine hydroxylase y globulin. Extracts were prepared from cells maintained for 24 h in F-14 mdeium containing 0.12 mM phenylalanine, 2% dialysed foetal calf serum and 0.04 mM ( $\triangle$ ) or 0.10 mM ( $\bigcirc$ ) tyrosine. Each tube contained an equivalent volume of extract to be assayed (0.64 mg protein per tube from the 0.04 mM tyrosine dish extracts, and 0.72 mg protein per tube from the 0.10 mM tyrosine dish extracts). So that each sample would contain the same total amount of  $\gamma$  globuling control  $\gamma$ -globulin fraction was added to bring them all to the same volume and the tubes containing no anti-tyrosine hydroxylase  $\gamma$  globulin contained only control γ globulin. The tubes were incubated at 25° C for 10 min, then at 0° C for 4 h and then assayed for tyrosine hydroxylase activity.

Extracts of the former cells contained 1.60 times as much enzyme activity as did extracts of the latter. Titration of extracts from cells grown in media containing other concentrations of tyrosine showed similar proportionality between enzyme activity and the amount of antibody necessary to achieve a given degree of inhibition. Thus, the increases in tyrosine hydroxylase activity are due to an increase in tyrosine hydroxylase molecules.

Increases in catechol and catecholamine synthesis in nerve cells in response to increasing levels of external tyrosine1,14,15 have been interpreted to imply that, at least under some conditions, uptake of tyrosine may be a rate-limiting step in catecholamine biosynthesis. Our results suggest that these observations also reflect the ability of tyrosine to increase the amount of cellular tyrosine hydroxylase. We have not yet determined whether the observed increase in tyrosine hydroxylase protein is due to increased synthesis or decreased degradation of the enzyme. Previous studies of increased enzyme activity in mammalian tissues caused by substrates have shown that the substrate can protect the enzyme against inactivation or degradation, for example, L-tryptophan on tryptophan oxygenase16.17, and thymidine on thymidylate kinase18. Further studies are necessary to confirm or disprove the possibility that increased extracellular tyrosine elicits an increase in neuroblastoma tyrosine hydroxylase protein by protecting the enzyme against degradation.

We thank Drs Seymour Kaufman and Marshall Nirenberg for support and advice.

# Lymphocyte cytotoxicity to isolated hepatocytes in chronic active hepatitis

CHRONIC active hepatitis is the term used to describe a chronic progressive liver disease with superimposed episodes of activity, which is characterised histologically by a dense mononuclear cell infiltrate in the portal tracts and piecemeal necrosis of periportal hepatocytes. Indirect evidence suggests that this may be an autoimmune disease. Antibodies reacting with smooth muscle, nuclei or mitochondria are present in the majority of patients¹ and there is also evidence of a cell-mediated autoimmune reaction as shown by the finding of inhibition of leukocyte migration by a human liverspecific lipopfotein (LSP)². This macrolipoprotein, when injected repeatedly into rabbits, will induce chronic aggressive hepatitis, and is thought to be a normal constituent of the hepatocyte plasma membrane³.

Work using antibody assays and immunofluorescence studies has demonstrated complete organ but incomplete species specificity, with cross reaction between the rabbit and human protein<sup>3</sup>. Here we describe the use of isolated rabbit hepatocytes for investigating the cytotoxicity of lymphocytes from patients with chronic active hepatitis, or other possible autoimmune liver diseases, and the role of the liver-specific protein as the principal antigen involved.

Twenty-two patients with chronic active hepatitis were studied. Tests were carried out in six patients with primary biliary cirrhosis, four with primary hepatocellular carcinoma, five with inactive alcoholic cirrhosis, one with idiopathic haemochromatosis and one with obstructive jaundice, and also in eleven healthy controls. Isolated rabbit hepatocytes were seeded into microtest culture plates (Falcon 3034) to achieve a final concentration of approximately 70 cells per well, and cultures were gassed with a 95% O<sub>2</sub>: 5% CO<sub>2</sub> mixture and incubated for 24 h at 37° C.

About 18 h after the establishment of the cultures, the supernatant was aspirated from each well and replaced with 10  $\mu$ l of lymphocyte suspension, the concentration of lymphocytes being adjusted to produce a lymphocyte to target cell (hepatocyte) ratio of 400: 1. After incubation at 37° C without agitation for 48 h the plates were inverted for a further 2 h and then carefully rinsed in medium 199. The number of hepatocytes remaining in each well was counted at ×60 magnification using a graticule eyepiece. Each experimental procedure was performed with at least 10 replicate wells, and each plate had its own group of 20 control wells. The difference between the mean number of cells in control and test wells, when expressed as a fraction of the former, gave the percentage cytotoxicity. Negative values have been represented as showing zero cytotoxicity. The range of cytotoxicity in control subjects so closely approximated to a normal distribution (mean 2.9%; s.d. 14.4%) that two standard deviations from the mean was thought to provide a reasonable estimate of the upper limit of the normal range.

Significant cytotoxicity was demonstrated in 20 (90%) of the patients with chronic active hepatitis, and was also present in two of the six patients with primary biliary cirrhosis (Fig. 1). In the 11 patients with other forms of chronic liver disease the results were similar to the controls, none showing significant cytotoxicity. Four of the 22 patients with chronic active hepatitis were untreated at the time of study and all showed significant cytotoxicity (56%, 70%, 89% and 84%). The remaining 18 cases were receiving various combinations of immunosuppressive drugs, and had shown improvement in biochemical liver function, but in only two did the result of the cytotoxicity test fall within the normal range. Serial studies in the four untreated patients, however, showed a significant reduction in the cytotoxicity following treatment with oral prednisone from a mean of 75-30% (t=3.2, P<0.05).

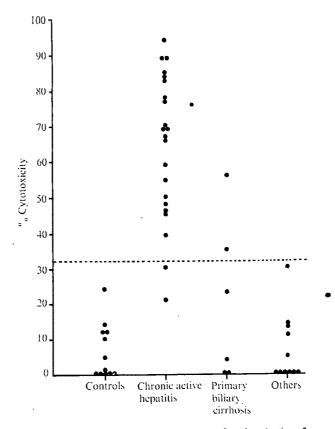

Fig. 1 Percentage loss of hepatocytes after incubation for 48 h with lymphocytes from patients with the various chronic liver diseases shown. The horizontal dotted line indicates the upper limit of the normal range (2 s.d. above the mean of the results in the controls). Lymphocytes were prepared from heparinised blood by dextran sedimentation and purified by cotton wool filtration<sup>4</sup> and centrifugation over a Ficoll/triosil gradient<sup>5</sup>. The final preparation contained, on average, 98% lymphocytes and 2°, monocytes. Three-month-old New Zealand White rabbits were used for the preparation of isolated hepatocytes. The liver was cut into small pieces and then incubated at 37° C for 12 h in RPMI 1640 containing foetal calf serum 10°, hyaluronidase 0.1°, collagenase 0.01%, DNase 0.005%, 1 M HEPES 2.3°, collagenase 0.01%, DNase 0.005%, 1 M HEPES dijusted to a pH of 7.35 in an atmosphere of 95°, O<sub>2</sub>:5% CO<sub>2</sub>. Short term tissue cultures were then prepared, the culture medium being identical to that used above but containing no enzymes. Indirect immunofluorescence using antisera obtained by immunisation of guinea pigs with the liver-specific cell surface antigen were used to verify that the cells were hepatocytes.

If this cytotoxicity is a consequence of specific sensitisation to LSP, the addition of excess of this lipoprotein should block the reaction. The mean cytotoxicity of four patients with chronic active hepatitis, when lymphocytes alone were added to the incubation chambers, was  $53.6 \pm 5.7\%$ . The addition of either human or rabbit LSP (0.5 µg per well), prepared from normal rabbit tissue and human organs<sup>6</sup>, together with the lymphocytes produced a highly significant reduction in cytotoxicity,  $5.3\pm3.0\%$  and  $5.5\pm5.5\%$  respectively. To confirm the specificity of this blocking reaction, a human kidney protein fraction, prepared in an identical manner to LSP, was added with the lymphocytes. The mean cytotoxicity in these conditions was almost identical to that obtained with lymphocytes alone (56.4  $\pm$  6.8). The addition of an antibody to LSP raised in guinea pigs, which by immunofluorescence was shown to coat the hepatocytes. completely blocked the cytotoxic reaction.

The blocking experiments clearly implicate sensitisation to human LSP in chronic active hepatitis as the important factor in the production of the lymphocyte-mediated hepatocyte injury. Indeed, preliminary analysis has shown a good

correlation between sensitisation to LSP as detected by the leukocyte migration test and the degree of lymphocyte cytotoxicity to isolated hepatocytes. Such sensitisation might be initiated by structural changes in the membrane lipoprotein following virus or drug-induced liver damage, but little information is available concerning either this aspect of pathogenesis or the aberrations in immunological control systems which may determine persistence of autoimmunisation.

# Intramembraneous changes on cationophore-triggered exocvtosis in *Paramecium*

Secretory vesicles ('trichocysts') of Paramecium contain proteins1 which are discharged by exocytosis. In P. aurelia (mating type VIII), trichocysts are firmly attached to the cell membrane before the onset of exocytosis, and membrane-intercalated granules occur at these contact sites (Fig. 1); these granules are arranged in a regular pattern and have been described previously as 'b-' and 'c-type granules'2. They are surrounded by a ring of 'a-type granules' which connect the cell membrane to the membrane of the alveolar sacs in the region where the latter are penetrated by the trichocysts<sup>2,3</sup>. When the trichocysts are expelled, the cell membrane is penetrated within the ring of a-type granules and the trichocyst membrane fuses temporarily with the cell membrane<sup>2</sup>. The present study takes advantage of several circumstances: (i) cells could be frozen without prefixation or cryoprotectants; (ii) exocytosis triggering involves only the final step of membrane fusion; (iii) the regular 'landmarks' in the plasmalemma serve to pinpoint intramembraneous changes occurring during exocytosis.

Exocytosis, monitored using the phase microscope, was triggered by enhancing transmembraneous ion flux via cationophores, that is, small molecules incorporated spontaneously into membranes. Intramembraneous morphological changes were analysed by freeze-fracture. Ionophores used were X-537 A (Hoffman-LaRoche), which complexes reversibly with mono- and bivalent cations, or A 23187 (E. Lilly), which complexes with bivalent cations only4. Exocytosis is connected in various cell types with Ca2+ influx5; the same ionophores also trigger exocytosis in

various other systems if Ca2+ is added6-8. In untreated paramedia, spontaneous trichocyst discharge is rarely observed. Addition of Ca<sup>2+</sup> to Paramecium cultures does not provoke discharge in the absence of ionophores. The Ca2+ content of the medium (0.4 mM), determined by atomic absorption with a Jarrel Ash unit, is much higher than the concentration thought to occur within Paramecium cells (10<sup>-4</sup> mM) (ref. 9) and is sufficient to trigger some exocytosis on addition of ionophores alone. Chelation of extracellular Ca<sup>2+</sup> with 2.5 mM EDTA, which only gradually immobilised the animals, prevented trichocyst exocytosis on addition of 0.10 mM X-537 A. With appropriate concentrations of ionophore A 23187 (0.07 mM) and Ca2+ (17 mM), practically all paramecia discharged almost all their trichocysts within 20 min before gross morphological changes were detectable on the cells or their trichocysts, although the latter extend to several times their resting length during expulsion. Preliminary attempts to localise intracellular Ca2+ suggested that a Ca2+ shift into the trichocysts precedes exocytosis (H.P., unpublished). Trypan blue did not penetrate into a given cell before exocytosis of most trichocysts was completed, which excludes a bypass of Ca2+ influx through gross membrane leaks.

During freeze-fracture the plasmalemma splits along a central plane in Paramecium<sup>2</sup> as in several other membranes<sup>10</sup>. The fracture face attached to the cytoplasm is called A face: the complementary view of the split outer half represents the B face. Cell membranes of controls exhibit on their A face b- and c-type granules at the sites of trichocyst attachments; c-type granules are especially visible as  $\sim 800$  Å clusters on the B face (Fig. 2a); the attachment sites of trichocysts are enclosed by a-type rings consisting of double (or occasionally single) rows of granules on the A face; corresponding holes occur on the B face. Since one cannot recognise on a replica of a freezecleaved cell membrane whether exocytosis has occurred,

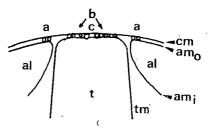

Fig. 1 a, a-Type ring of membrane-intercalated granules, connecting cell membrane and alveolar membranes; al, alveolar cavities (interrupted at sites of trichocysts); ami, (amo) inner (outer) membrane of alveolar cavities; as, alveolar septa; b, diffuse aggregates of membrane-intercalated particles (located within a-type rings) at contact sites between cell membrane and trichocyst membrane; c, ~800 Å large patch of membrane-intercalated particles at the centre of the site of contact between trichocyst membrane and cell membrane; cm, cell membrane (dotted); t, trichocyst; tm trichocyst membrane.

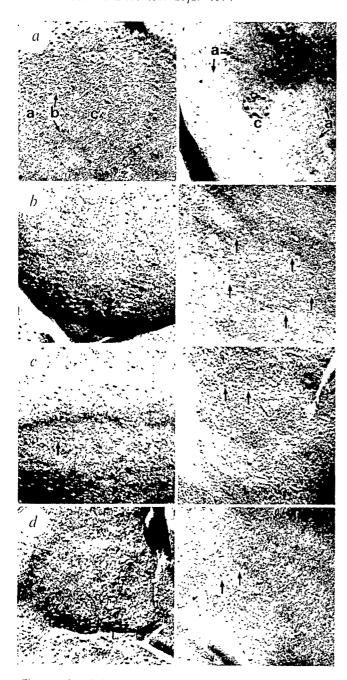

Fig. 2 A face (left) and B face (right) of the split cell membrane after freeze-cleaving. Controls (stage a) are compared with different stages of morphological changes after triggering exocytosis (stages b-d) obtained by adding 0.07 mM ionophore A 23187 and 17 mM  $Ca^{2+}$  for 15–18 min. Stages b-d may be encountered in close vicinity within one animal; c-type granules invariably disappeared after exocytosis. Stage d could be identified on the basis of the regular geometrical arrangement of trichocyst attachments on the body surface². All samples were frozen in Freon 12 without prefixation or cryoprotectants, cut at  $-100^{\circ}$  C and shadowed with platinum-carbon in a Balzers BA 360 M freeze-etching unit. Micrographs are mounted with white shadows, the shadow casting direction is from bottom to top. a-Type rings and their remnants (arrows) appear as granules on the A face and as corresponding holes (faintly visible) on the B face. ( $\times$  100,000.)

conditions were chosen, where complete triggering of exocytosis was achieved. After exocytosis a-type rings persisted in various degrees of decomposition on A and B faces (Fig. 2b-d, Table 1) and could therefore be used as 'landmarks' to locate the sites where exocytosis had taken place; furthermore, these sites are located at predictable points of the body surface<sup>2</sup>. After exocytosis, c-type granules almost

invariably disappeared from the B face (Fig. 2b-d, right); b-type granules also seem to be dispersed, although they are arranged diffusely, even in controls. a-Type rings often persist as fragments, although the number of non-oriented particles seems greater in regions where a-type rings undergo decay (Fig. 2c, left). This suggests that granules are dispersed by lateral movement and that after exocytosis the cell membrane is resealed by lateral diffusion of membrane (lipid) constituents; this latter assumption is further supported by the observation that a-type rings are smaller in triggered cells than in controls (Table 1). Ultrathin sections show that the dispersion of a-type rings in the period following massive trichocyst discharge could be caused by a gradual detachment of the plasmalemma after exocytosis and membrane resealing have been completed. Thus, the most specific change related directly to exocytosis is the disappearance of c-type granule aggregates. Since these are present within most of the a-type rings in unstimulated, normal cells, their occurrence cannot be explained by membrane fusion during exocytosis<sup>11,12</sup>; rather, in Paramecium they represent stable structural elements at the sites where trichocysts are attached permanently to the plasmalemma prior to the membrane fusion occurring during exocytosis.

The intracellular membrane-to-membrane attachment sites2 of types a-c in normal Paramecium do not represent selective permeability sites which would be directly analogous to gap junctions13. This follows from studies with electron microscopic tracers such as La(OH)3; all membraneto-membrane attachment sites of Paramecium are also impermeable to (2% w/v) microperoxidases (haemoligopeptides, molecular weight approximately 1,700-1,900), applied to living Paramecium over several days (H.P., unpublished). If, during spontaneous exocytosis, the membrane-intercalated particles function in analogy to ionophores (not resolvable in replicas) the particles would have to be capable of very rapid permeability changes specifically for Ca2+. Other functional aspects of membrane-intercalated particles, such as the possible role of lipid constituents in membrane fusion<sup>14</sup> and Ca<sup>2+</sup>-dependent ATPases<sup>4</sup> possibly being involved in exocytosis also have to be considered.

Table 1 Morphological changes of a-type rings in freeze-fractured replicas after exocytosis\*

•				
Treatment		ition stages Frequency‡		(nm)§ Large diameter
Controls	b - d	97 3	254±43	$313 \pm 36$
15-18 min 0.07 mM ionophore A 23187 - 17 mM Ca <sup>2+</sup>	+ b c d	$ \begin{array}{c} 0 \\ \sim 28 \\ \sim 26 \\ \sim 46 \end{array} $	195±38	243±29

\*Samples were processed for freeze-cleaving as described in Fig. 2. †Stages of decomposition (a-d) are as defined in Fig. 2.

Numbers of a-type rings counted were 59 for controls and 39 after exocytosis.

\$Values  $\pm$  s.d. Since trichocysts do not occur over the whole body surface, only those regions surrounded by intact or clearly visible remnants of a-type rings were evaluated; frequency values show that in such regions a-type rings are only rarely missing in controls: therefore, values determined for stage d after exocytosis are necessarily minimum estimates.

As discharge is very rapid, time sequence studies of morphological changes could not be performed. The occurrence of similar granular membrane specialisations has been reported not only in *Tetrahymena*<sup>11,12</sup> and *Paramecium*<sup>2</sup> but also in connection with transendothelial movement of cytopempsis vesicles<sup>15,16</sup>. In contrast, no such intramembraneous differentiations were observed in various gland cells<sup>17–20</sup>, stimulated or unstimulated. In these cases, membrane-to-membrane attachment might possibly have escaped detec-

tion, either because it is an ephemeral event or because of the pretreatments commonly used before freezing. Non-cryoprotected Paramecium, however, cationophoremediated transmembraneous Ca2+ influx provokes trichocyst exceytosis, accompanied by specific changes of structural subunits preforms within the membrane portions involved.

I acknowledge the help of Professors L. Bachmann and F. Miller in the course of this work; the performance of calcium determinations by Dr W. Strele; the technical assistance of Mrs D. Wolfram; the provision of ionophores by Hoffmann-LaRoche and E. Lilly; the support by the Deutsche Forschungsgemeinschaft.

## Acute hepatic injury by vinyl chloride in rats pretreated with phenobarbital

LITTLE is known about the biological effects of vinyl chloride monomer (VCM) despite its wide industrial use. In 1973, thousands of workers were involved in producing, processing and moulding VCM into 15 billion pounds of its polymer (PVC)1. Angiosarcoma, a rare liver cancer, has recently been linked to occupational exposure in man2 and long term inhalation of low doses in animals3. Occupational vinyl chloride exposure has also been associated with increased incidence of hepatic cirrhosis, splenomegaly, decreased bromosulphalein clearance from blood and acro-osteolysis4.5. Reports of acute hepatic injury after vinyl chloride inhalation are limited and the findings relatively nonspecific<sup>6,7</sup>.

VCM, readily reactive in free radical-mediated industrial polymerisations, may interact with liver mixed function oxidase system (MFOS), an intracellular enzyme complex located within the membranes of the endoplasmic reticulum. This system is known to activate other halogenated hydrocarbons into hepatotoxins\*. Therefore, we set up an experiment to determine whether the potential of VCM for liver injury was enhanced in animals pretreated with phenobarbital (PBT), an inducer of certain enzymes of the MFOS.

Male Holtzman rats (300 g) were exposed once to air, or air containing 0.5, 5 or 10% VCM for 6 h or to air alone or air containing 0.5 or 5% VCM for 6 h on each of 5 consecutive days in a dynamic inhalation chamber previously described. VCM was obtained from Matheson Gas Corporation. Rats were given untreated drinking water regularly or they were pretreated with sodium phenobarbital (0.1%) in the drinking water beginning 7 d before exposure to VCM. This dose, which corresponds to 100 mg kg<sup>-1</sup> d<sup>-1</sup>, is sufficient to double both cytochrome *P*-450 content and oxidative N-demethylase activity<sup>10-11</sup>. Four experimental groups were defined: (1) exposed to air and not pretreated; (2) exposed to VCM and not pretreated; (3) exposed to air and pretreated with PBT; and (4) exposed to VCM and pretreated with PBT. Animals were killed 24 h after the single exposure, or immediately after the fifth. Blood was collected to measure serum enzyme activity indicative of liver damage". The liver tissue was prepared for histological examination by perfusion fixation through the portal vein with buffered 1% glutaraldehyde. Selected blocks were post-fixed with OsO<sub>4</sub>. Thin sections of Epon-embedded liver were examined by electron microscopy<sup>11</sup>.

Alanine-u-ketoglutarate transaminase activity: mg pyruvate ml-1 h-1. Sorbitol dehydrogenase activity; units ml-1 min-1

Expressed as mean 's.e. or as range.

The biochemical data from these experiments are shown in Table 1. In this table, both non-pretreated and PBT-pretreated animals exposed to air alone had no rise in levels of serum alanine-α-ketoglutarate transaminase (EC 2.6.1.2, AKT) or sorbitol dehydrogenase (SDH), another cytoplasmic liver enzyme whose appearance in serum correlates with liver injury<sup>12,13</sup>. We have previously shown this enzyme to be highly specific for several types of liver injury<sup>14</sup>.

In non-pretreated groups, exposure to 0.5% or 5% VCM for a single 6-h period did not cause a substantial rise in either serum AKT or SDH activity. Only after exposure to 10% VCM was there a slight increase in either parameter of hepatoxic response. In these animals, livers were histologically normal at the lower dose levels of VCM (Fig. 1a), and centrolobular hepatocellular vacuolisation was noted only in the group exposed to 10% VCM. During exposure to this higher dose level, animals appeared to be anaesthetised.

By contrast, PBT pretreatment for 7 d caused a marked enhancement of injury at the 5% level of exposure. Rats exposed to 0.5% were without apparent injury, determined biochemically. In the PBT-pretreated rats exposed to 5% VCM a clear morphological response was observed with striking vacuolisation of centrolobular parenchymal cells (Fig. 1b). There was also focal necrosis of mid-zonal parenchyma which became confluent towards the dorsal aspect of the liver. This vacuolated change corresponds to dilation of the rough endoplasmic reticulum as seen by electron microscopy. Smooth

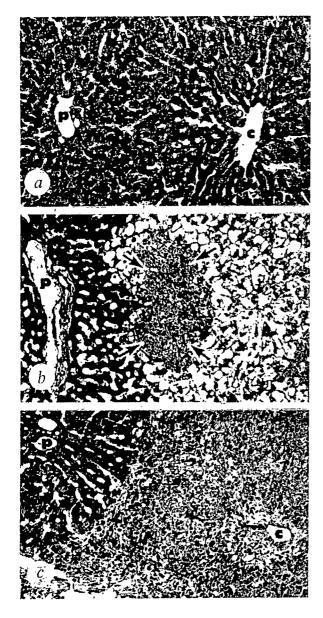

Fig. 1 Liver: portal areas (p) on left; central veins (c) on right. a, Non-pretreated rat 24 h after 6-h exposure to 5% VCM. b, PBT rat 24 h after 6-h exposure to 5% VCM. There is extensive vacuolisation of centrolobular parenchyma on right and a focus of midzonal necrosis at centre (arrows). c, PBT rat immediately after last of five 6-h exposures to 5% VCM at 24-h intervals. Necrotic centrolobular parenchyma on the right has been removed, remaining connective tissue stroma is infiltrated by macrophages. Vacuolated parenchymal cells are not seen. Stain: haematoxylin and eosin. < 150.

endoplasmic reticulum in involved cells form tubular snarls with foci of increased electron opacity suggesting of membrane denaturation11. In one of four PBT-pretreated animals exposed to 0.5% VCM, such vacuolisation, but not necrosis, was also observed. As noted previously, centrolobular vacuolisation was seen only in livers of non-pretreated rats exposed to 10%

The serum from PBT-pretreated rats killed after the last exposure to 5% VCM following 5 consecutive days of exposure did not contain raised activities of either serum AKT or SDH. This suggests that acute hepatotoxic injury was not cumulative, or that previous exposure to VCM blocked the biochemical response which followed re-exposure at short intervals<sup>15</sup>. Preliminary time course studies showed that increases in serum enzyme activities reached a maximum 24 h after the start of VCM exposure. Thus, injury from day 4 of exposure should have been shown on day 5 when rats were killed. Instead of a

biochemical lesion, Fig. 1c shows that livers of PBT-pretreate animals successively exposed to 5% VCM contained broa areas of parenchymal loss and stromal collapse most prominer towards the dorsal aspect of the liver. These bands correspon in distribution to the bands of confluent necrosis seen after single exposure. Although these animals were killed 24 h afte the fourth exposure, and immediately following the fifth, the. was neither vacuolisation nor acute focal necrosis finding indicative of recurrent acute injury. Results of the multiple 5' VCM exposure suggest that PBT-pretreated animals are protected against recurrent acute hepatocellular injury from dai VCM exposure by previous injury-inducing VCM exposur Livers from non-pretreated animals similarly exposed up to 5° VCM on 5 consecutive days were indistinguishable from nor pretreated animals exposed to air.

The hepatotoxicity of vinyl chloride may be caused by mechanism similar to that of other non-symmetrically chloric ated ethylenes such as trichloroethylene (TCE). Inductic of MFOS enzymes by pretreatment with PBT or 3-methy cholanthrene enhances the hepatotoxicity of TCF16, possibl through an increased rate and/or altered route of metabolism1 Interestingly, after an initial exposure to TCE, the in viv metabolism following subsequent exposures is not reduced but the ratio of secondary metabolites found in the urin changes18. From our data, the initial exposure to VCM seem to protect against acute injury on re-exposure for at least 5 c Perhaps, this initial exposure alters the pathway of activation of VCM in a manner not unlike that proposed for CCl<sub>1</sub> (ref. 15 which destroys MFOS enzymes involved in its metabolic activa tion to a hepatotoxin. Like TCE19, the metabolism of VCM ma proceed through an epoxide intermediate. Activation to reactive electrophile20 is also in keeping with the tumorigenia potential of VCM. Experiments to define the interactions o VCM and the MFOS are underway.

## Application of β-D-glucuronides and glucose together suggests a new direction for cancer chemotherapy

KNOWN anti-cancer agents are unselective, attacking not only tumour cells but also other rapidly proliferating cells such as lymphocytes. Any difference between tumour and normal cells which might provide a basis for specific chemotherapy has therefore aroused interest. One such difference is the lower pHvalue of tumour tissue (about 6) compared with most normal tissue (about 7.3) in the presence of glucose<sup>1,2</sup>.

The lysosomal enzyme  $\beta$ -glucuronidase has a  $\rho H$  optimum of 5.2 (ref. 3). We report here that the glucuronidase activity of tumours is selectively enhanced by previous administration of glucose, presumably because glucose selectively lowers the pH of tumour cells. Since glucuronides are biologically inactive4.5, our observation would suggest the possibility of designing drugs which are preferentially activated in tumour cells.

Tumour cells  $(5 \times 10^5)$ , counted with a haemocytometer, were implanted subcutaneously in the neck of a male Hauben rat (6 weeks old). The spindle-shaped sarcoma was induced in 1968 using methylnitrosourea and repeatedly transplanted<sup>6</sup>. After 4 weeks the rat bearing the tumour was treated six times with glucose (2 g kg<sup>-1</sup>) (50% in phosphate buffer pH 7.3) intraperitoneally at 40 min intervals. Two hours after commencing treatment, β-hydroxyquinoline-β-D-glucuronide (Light, Colnbrook, UK, 500 mg kg<sup>-1</sup>, suspended in the glucose solution) was applied intraperitoneally. Six hours after beginning the experiment, the animal was killed, using ether. The tumour and surrounding muscle were removed, and 1 g of each tissue homogenised in 5 ml distilled water in a Potter homogeniser. The homogenates were then continually extracted with boiling ether for 2 h, the ether extracts dried over Na<sub>2</sub>SO<sub>4</sub>, evaporated to approximately 0.5 ml and the residue investigated by thin layer chromatography (TLC) (Silufol UV<sub>254</sub>, Kavalier, CSSR). 8-Hydroxyguinoline was present in the tumour extract, but not in the muscle extract ( $R_F$  0.39 in benzene/acetone (1:1) and 0.143 in benzene/methanol (95:5), identical with those of the control sample). 8-Hydroxyquinoline was detected using its UV-extinction property.

	Table 1 Ex	tinction o	f tissue homogenates at 480 nm
	Tumour	Muscle	
E*480	0.254	0.073	†Treated with 8-hydroxyquinoline-β-D-
E*480	0.078	0.083	glucuronide and glucose †Treated with 8-hydroxyquinoline-β-D- glucuronide
E*480	0.084	0.082	†Untreated for control

E\*480 of a solution of 0.1 mg 8-hydroxyquinoline in 1 ml 2 N NaOH + 2 ml reagent = 0.375.

†All rats were approximately the same weight (200-220 g) and had tumours of approximately the same size (1 g).

A second tumour-bearing rat was similarly treated; the ether solution of the homogenates was totally evaporated, and the residue treated with 1 ml 2 N NaOH and 2 ml of a reagent containing diazotated p-nitroaniline. The extinction was measured at 480 nm (Table 1).

A third rat was treated with 8-hydroxyquinoline-β-D-glucuronide (500 mg kg<sup>-1</sup>, suspended in 2.5 ml phosphate: buffer pH 7.3), but without glucose. The extracts were prepared as described above and investigated using TLC and photometry. 8-Hydroxyquinoline was not detected in the tumour or in the muscle extract (Table 1).

Two more rats, each bearing a neck tumour, were treated with 2-naphthyl- $\beta$ -D-glucururonide sodium salt (330 mg kg<sup>-1</sup> Koch-Light Colnbrook), together with glucose (12 g kg<sup>-1</sup>), and two other rats with the glucuronide without glucose. We could only detect 2-naphthol in the tumour extracts of the rats treated with both 2-naphthyl-β-p-glucuronide and glucose. Barely visible traces of 2-naphthol were detected in the other tissue homogenates. The extracts were investigated using TLC (silica gel), R<sub>1</sub> 0.31 in benzene/methanol (95:5) and 0.61 in benzenedioxan-acetic acid (90:25:4), identical to those of the control sample. Diazotated benzidine8 was used for detection.

The 2-naphthole content in the tumour tissue was also measured quantitatively. The residue of the extracts was dissolved in 2 ml ethanol and 0.02 ml of a solution containing diazotated benzidine (0.5 g benzidine in 0.14 ml concentrated HCl and 98.6 ml water mixed with 100 ml 10% NaNO<sub>2</sub> in water) were added. The extinction was measured at 415 nm against a solution of 0.02 ml reagent and 2 ml C<sub>2</sub>H<sub>5</sub>OH (Table 2).

	Table 2 Ex	tinction o	of tissue homogenates at 415 nm

†All rats were approximately the same weight (200-220 g) and had tumours of approximately the same size (1 g).

Analogous results were obtained on repeating all experiments. We have therefore shown that previous glucose administration selectively enhances tumour glucuronidase activity. This has implications for the design of anti-cancer drugs<sup>9,10</sup>; inactive glucuronides of active drugs, for example, the O-glucuronide of p-hydroxyaniline mustard<sup>11</sup>, could be selectively activated in tumour tissue by this procedure. The synthesis of similar conjugates and investigations about its anti-cancer activity are in progress.

#### Fatigue in frog single muscle fibres

WHEN a whole striated muscle is stimulated repetitively, its contractile force decreases and it is said to be fatigued1-3. Fatigue does not occur in dystrophic muscles, and is characteristic of fast but not slow mammalian and amphibian muscle fibres<sup>4,5</sup>. The complexity of the excitation-contraction process in fast muscle fibres has made it difficult to determine when fatigue sets in. Restoration of twitch tension of fatigued fibres by caffeine<sup>6.7</sup> suggests that fatigue is a failure of calcium release, although the depletion, during prolonged contraction, of necessary energy-rich metabolites8.9 could be responsible for fatigue. Contraction can be uncoupled from calcium release and excitation by hypertonic solutions (refs 10-12 and unpublished results of S. R. Taylor, R. Rudel and J. R. Blinks). We have now found that hypertonic uncoupling prevents fatigue, so that fatigue must be linked to contraction. We have also found that single muscle fibres can recover after being fatigued by prolonged tetanisation.

Single, fast muscle fibres of the semitendinosus muscle of frogs (Rana pipiens) were used, rather than whole muscle, to avoid the rate-limited diffusion and the heterogeneous fibre

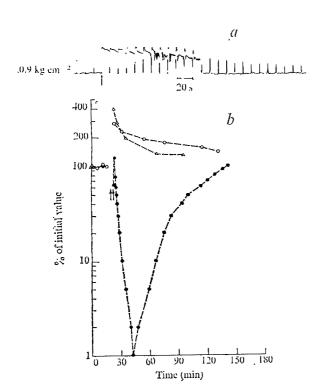

Fig. 1 a, Tension recording from a single muscle fibre tetanically stimulated at 20 Hz. Arrow indicates onset of stimulation. Recovery intervals correspond to 1 s without stimulation. Twitches are shown before and immediately after the tetanus. b, Logarithmic graph of peak tension ( $\bullet$ ), contraction time ( $\cup$ ), and relaxation time ( $\wedge$ ) of twitches from the same experiment as in a. Values plotted are percentages of pre-tetanic levels. The absolute initial values of the parameters are respectively 1.14 kg cm<sup>-2</sup>, 56 ms and 125 ms. The period between arrows indicates the tetanisation period.

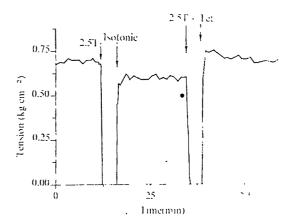

Fig. 2 Twitch tension blockage and recovery from immersion in Ringer made 2.5 times (T) isotonic by addition of Na SO<sub>1</sub>. Arrows indicate immersion period. During the second immersion the fibre was tetanically stimulated at 20 Hz for 120 s.

population in whole muscle<sup>13,14</sup>. A fibre was dissected and mounted in a bath of flowing medium at 15 °C. Tension was recorded by a RCA 5734 transducer tied to one end of the fibre, and was displayed on an oscilloscope screen and a paper chart recorder. Sarcomere length was measured by reading the interline distances of a laser diffraction pattern of the fibre 15, and was adjusted to 2.3 µm. The fibre was stimulated by external platinum electrodes with 0.3 ms condenser discharges. Isometric twitch tension was between 0.7 and 1.2 kg cm 2 and tetanic tension at the beginning of tetanus varied from 1.6 to 2.2 kg cm<sup>-2</sup>.

Figure 1a shows a typical response of a fibre to tetanic stimulation at 20 Hz for 120 s with interruptions of 11 s. During stimulation, tetanic tension decreased to 54% of its initial value in a graded rather than in an all-or-none fashion<sup>16</sup>. In the experiment, the twitch tension that followed the tetanus initially was lower than pre-tetanic control, increased transiently within 10 s and then decreased to close to zero at 10 min (Fig. 1b). It returned to the baseline during a prolonged recovery period of about 100 min (Fig. 1b).

The initial and short-lived increase in twitch tension after a tetanus represents post-tetanic potentiation, which is ascribed to a redistribution of calcium within the sarcoplasmic reticulum<sup>18</sup>. The increase is associated with prolongation of contraction time (time-to-peak tension) and of relaxation time(timefrom-peak tension to baseline, Fig. 1b), also characteristic of post-tetanic potentiation16-18.

In contrast to the prolonged recovery of twitch height after tetanic stimulation in isotonic Ringer (Fig. 1b), recovery of twitch height after immersion in hypertonic Ringer (made 2.5 times (T) isotonic by adding sucrose or Na2SO1) was not affected by tetanic stimulation (Fig. 2). Fibres stimulated in hypertonic Ringer recover their basal twitch tension with a half time of  $53 \pm 15$  s.e. (n = 4) s, compared with a half time of recovery in isotonic Ringer of  $72 \pm 7$  s.e. (n - 3) min. As Fig. 2 shows the rate of recovery of twitch height after tetanic stimulation in hypertonic solution did not differ from the rate after simple immersion. The latter process depends on diffusion of water and hypertonic solute between bath and fibre 13.

These results indicate that the decrement in twitch tension . characteristic of fatigue in single muscle fibres is not due to an intrinsic failure of the calcium release mechanism in excitationcontraction coupling. Contraction is a process that consumes energy<sup>8,9</sup>. Tetanic contraction fatigues the muscle fibre probably by depleting energy stores, which in turn may affect the release of calcium so that twitch tension is reduced.

We thank Drs S. R. Taylor, R. Rüdel and J. R. Blinks for showing us their unpublished records about aequorin luminescence during immersion in hypertonic solutions. J. L. V. is a recipient of a postdoctoral fellowship from the Muscular Dystrophy Associations of America.

#### Effect of dantrolene sodium on calcium movements in single muscle fibres

Dantrolene sodium or 1-[5-(p-nitrophenyl) furfurylidene amino] hydantoin sodium hydrate (DaNa) is a long-acting drug with skeletal muscle relaxant properties which has recently seemed clinically useful in the treatment of some types of muscle hypertonia<sup>1,2</sup>. DaNa does not affect neuromuscular transmission nor the electrical properties of skeletal muscle<sup>3</sup> and it apparently involves the processes of excitation-contraction coupling<sup>1,3,4</sup>. The mode of action of DaNa has not been studied before or single muscle fibres and here we provide direct evidence that DaNa interferes with the intracellular movements of calcium ions.

Rana temporaria (60 g) kept at 15° C and force fed twice a week with 1-1.5 g chopped beef were used. Single skeletal muscle fibres of the fast twitch type were isolated by microdissection from the dorsal part of the semitendinosus muscle. The fibres diameter 70-150 µm were kept in a standard phosphate Ringer solution<sup>5</sup> at pH 7.2 and they maintained their physiological properties (including electrical threshold) for several hours. When dissected, the muscle fibre was transferred into a small (1.5 ml) Perspex chamber and mounted horizontally. with one of its tendons hooked to the anode of a RCA 5734 mechano-electrical transducer tube. A home-made Perspex four-way tap allowed the thorough replacement of the chamber fluid within about 1 s. A continuous circulation system with appropriate bypasses maintained the temperature of the experimental solutions and of the chamber at 18° C. Electrical pulses of 0.2 ms duration and 1.2 times threshold were delivered

through a pair of bright platinum wires fixed 10mm apart in the bottom of the chamber at right angles to the fibre. DaNa freshly dissolved in phosphate Ringer was applied at a concentration of 10 µM. This produced a mean depression of the twitch force by 58% (eight experiments) within 30 s and an additional 6% decrease during the next 10 min (Fig. 1a). The twitch contraction time and relaxation time were shortened. The action of DaNa was much more rapid for these single muscle fibres than for the whole muscles studied previously. Most of our data were collected within about 6 min of exposure DaNa. The effect of the drug was reversible on return to normal Ringer but a complete recovery of the twitch force took 30-60 min.

When the isometric twitch force was markedly reduced by DaNa, the tetanus force for a 1.5 s supramaximal stimulation at  $100^{-1}$  s was not significantly reduced. The finding of a large reduction of the twitch with little, if any, change in tetanus tension bears out the earlier results on whole muscle<sup>1,4</sup> and indicates that DaNa does not impair the maximum capacity of the muscle fibre to produce force. The recorded reduction of the twitch force by DaNa must therefore be related to an inhibition of some step in the process of mechanical activation, as the membrane spike generation is not impaired3.

A useful way to approach this problem is by recording single fibre contractions to known increases in the external potassium concentration whereby Hodgkin and Horowicz mechanical threshold<sup>6</sup> can be estimated. Figure 1b shows a near maximum contraction of a fresh muscle fibre suddenly exposed to 50 mM

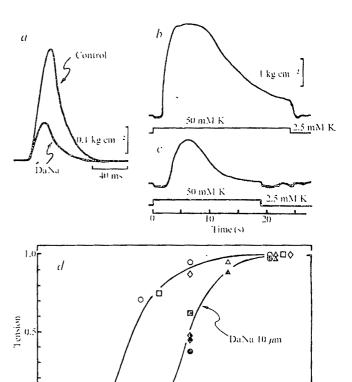

Fig. 1 Effect of DaNa on single muscle fibre. a, Superimposed isometric twitches elicited by supramaximal pulses before and in presence of DaNa; b and c, contractions elicited by a rapid increase in external K from 2.5 to 50 mM (see step), b, before and, c, in the presence of DaNa. Trace 1, isometric tension; trace 2, calcium mediated light emission; trace 3, membrane response. Fibre diameter 1.8 mm. Mean intracellular resting potential - 59 mV. Temperature of solutions 21 C.

K. Four min after bathing the fibre in 10 μM DaNa (Fig. 1c) a second exposure to 50 mM K elicited a contraction which was reduced by more than 50%. The latency of this contraction was increased and its rate of rise reduced while the subsequent spontaneous relaxation during the maintained K exposure was quicker than in Fig. 1b. These effects of DaNa were reversible. The graph of Fig. 1, d shows similar data for different concentrations of K in four different muscle fibres. The peak force of each K contraction is expressed with respect to the maximum force recorded in the same fibre during exposure to 117 mM K. These maximum contractions were not significantly affected by 10 μM DaNa in the present single fibre experiments and we think the reduction reported by others' must have been related to their use of whole muscle preparations. The effect of lower K concentrations, however, was markedly reduced and the curve was shifted to the right by a factor of about 1.7. The mean threshold for K contractions was approximately 20 mM in untreated fibres and 35 mM K after 1 min in 10 µM DaNa.

The observation that DaNa reduces both submaximal potassium contractions and twitch force without significantly affecting the maximum potassium contractions or the tetanus force could be explained by an inhibitory effect on some intracellular step in excitation-contraction coupling. To analyse this possibility, single muscle fibres from the barnacle *Balanus nubilus*<sup>7</sup> were injected with aequorin, the calcium-sensitive

bioluminescent proteins. Several thousands of the jellyfisl Aeguorea forskalea were collected at Friday Harbor Labora tories during summer, 1973, and the extracted aequorin wapurified in Brussels, using standard techniques". Lach barnacle muscle fibre of 1.0-2.0 mm diameter was cannulated with  $\epsilon$ Pyrex tube of 200 µm diameter and mounted vertically in a light-tight black Perspex chamber. The calcium-mediated light output was recorded on a Tektronix oscilloscope with ar EMI 9635 photomultiplier tube. When the injected muscle fibre was placed in front of the photomultiplier, the rate of light emission related to the intracellular ionised calcium (resting glow) showed a rapid decrease during the first 30 min and then stabilised at a rather steady level as the [Ca], is very low in the resting state and the rate of consumption of the injected aequorin is small. In these conditions, the replacement of the normal seawater by DaNa seawater was followed by a decrease of the resting glow to a lower level which depends on the drug concentration.

This reduction of the intracellular Ca concentration by DaNa could result either from a reduced resting Ca<sup>2</sup> influx, or from an increased resting Ca<sup>2</sup> efflux or from a direct action involving the intracellular Ca stores. To distinguish these possibilities, the aequorin-injected muscle fibres were tested in 0 Ca 1 mM EGTA artificial seawater, and DaNa 35 µM still reversibly reduced the resting glow by about 20% (Fig. 2a c) which suggests that the DaNa effect is not dependent on any reduction in resting Ca<sup>2</sup> influx. The second alternative could also be excluded in other experiments in which the leakage of <sup>45</sup>Ca into external seawater was estimated in barnacle muscle fibres loaded by an intracellular injection of 0.1–0.2 µl <sup>45</sup>Ca in Tris buffer at pH 7.2 (ref. 10). The resting calcium efflux was actually decreased by 35 µM DaNa which implies that the reduced intracellular calcium cannot result from an increased loss.

Therefore it would seem that DaNa acts primarily on the intracellular Ca storage sites to reduce the level of free sarcoplasmic calcium. This third alternative is indeed supported by studies of the calcium transient recorded during single contractions of barnacle fibres injected with aequorin. The fibre was stimulated at intervals of at least 20 s through an intracellular silver wire with a constant current pulse of 150 ms while the membrane potential was recorded with another intraceilular platinum electrode connected to a high input impedance amplifier8. Although the actual membrane depolarisations thus elicited were identical before and after DaNa (third trace in Fig. 2d and e), the mechanical force (first trace) produced by the stimulated muscle fibre was reduced by 20% after DaNa 35 µM while the transient increase in aequorin luminescence (second trace) decreased by about 30% in this example. These results were regularly recorded in the six different barnacle muscle fibres studied, each one being tested with various combinations of stimulus durations and intensities.

In conclusion, DaNa depresses the mechanical force output of single muscle fibres by an inhibitory effect involving the calcium movements at intracellular storage sites, both at rest and during electromechanical activation.

#### Simultaneity, occlusion and the sodium pump

GARRAHAN and Garay<sup>1,2</sup> have shown that for the sodium pump of the human red blood cell, the half-saturation concentration for transport of a particular cation from one face of the membrane is not affected by the type or concentration of cation at the opposite face. This finding is consistent with previous observations on the squid axon3 and the sheep red blood cell4. The simplest explanation of these results, according to Garrahan and Garay<sup>2</sup>, is that the pump binding sites are at equilibrium with cation and that transport occurs only when cations are bound simultaneously at both faces of the membrane. Their view is that previously proposed "sequential" models<sup>5</sup> must be rejected and replaced by models in which cation binding sites are present simultaneously on both sides of the membrane. In addition, they show that the transport data are sufficient to reject a model (Fig. 1c) if the pump exists for a substantial time in a conformation in which bound cations are occluded. Yet there is biochemical evidence6 that, at least at 0° C, the pump does nonetheless exist in an occluded state for an appreciable time. Here we show that this apparent paradox is resolved by the tetrameric internal transfer model<sup>7</sup> of Fig. 1d.

The simplest 'simultaneous' models are shown schematically in Fig. 1; the applicable steady state kinetic schemes and their solutions are shown in Fig. 2 (for models a and d of Fig. 1) and in Fig. 3 (for models b and c). We first consider the model of Fig. 1a, Here, a binding site which is sodium-selective in one conformation moves physically across the membrane and becomes potassium-selective in the other conformation8. In the kinetic solution (see Fig. 2), the halfsaturation concentrations for transport, being simply the constants  $K_S$  and  $K_P$ , are independent of the trans cation as required by the experimental data<sup>1-4</sup>. This model makes no provision, however, for an occluded form and in Fig. 1b we have generalised to allow for this possibility. But in doing so we see from the kinetic solution (Fig. 3) that the half-saturation concentrations are no longer  $K_S$  and  $K_P$ but are variables which depend on the trans concentration of cation. Only if the concentration of the occluded form is a negligible fraction of the doubly-bound open forms will the experimental transport observations be satisfied; this conclusion is valid even for a more general model with a succession of occluded forms.

Figure 1c and d show two types of internal transfer model<sup>9,10</sup>. A basic feature of such models is the presence of occluded forms. During each conformation change, transportable substrate is moved only part of the way across the membrane, since the binding sites themselves move only. between a bathing solution and an internal cavity. Within this internal cavity, substrate can move from one binding site to the complementary site. During a second conformation change, substrate can then move out of the internal cavity and into the opposite bathing solution. Garrahan and Garay<sup>2</sup> have shown that the dimer model (Fig. 1c) yields the kinetic solution of Fig. 3, so that once again the concentration of the

occluded form would have to be insignificant. Finally, for the tetrameric internal transfer model (Fig. 1d), the simple kinetic scheme and solution of Fig. 2 are appropriate, because the steps labelled 'transport' now represent the release of substrate which entered the internal cavity during the preceding conformation change.

In summary, of the four 'simultaneous' models of Fig. 1, only the tetrameric internal transfer model both accounts for the experimental transport observations1-4 and allows for the existence of an occluded form during an appreciable fraction of the transport cycle. Thus, to distinguish between these models, one need only determine whether or not the fully-bound forms of the pump exist to an appreciable extent in occluded states.

What appears to be an occluded form of the pump from guinea pig kidney has been detected by Post et al.6. From their data it is possible to obtain a rough estimate of the

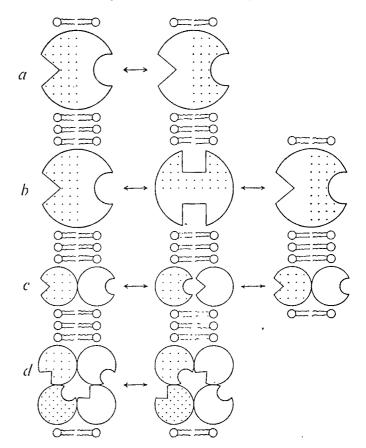

Fig. 1 Simple 'simultaneous' models for active transport. For each model, transport of substrates (not shown) occurs as a result of transitions between the depicted conformations of the transport protein. The substrate binding sites are the sharp, round, and square indentations; the sharp sites are specific for one substrate, the rounded for the second substrate, while the square sites are of undefined specificity. Notice the changes in specificity of a given site from one conformation to another. Only those portions of the transport proteins immediately adjacent to these binding sites are shown; stippling is used to distinguish these regions during the conformation changes. For example, although the two conformations in model a are functionally equivalent, the stippling indicates that they are not physically equivalent, but that the sites have moved completely across the membrane and switched their specificities during the conformation change. Notice that models b-d possess sites in occluded locations, while c and d are in addition internal transfer models<sup>0.10</sup>. Two postulates made for all models are that the binding sites are in equilibrium with the substrates and that conformation changes occur only when all of these sites are fully occupied. (Although each site may require the binding of more than one substrate particle to be completely occupied, the analysis is simpler and the essential points are unaffected by taking the case of only one particle per site.) The drawings are of course wholly schematic, describing the formal basis of the transport events but not the detailed structural features of the transport proteins.

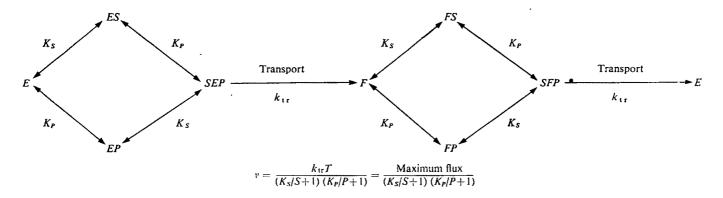

Fig. 2 Kinetic scheme and steady-state solution for the transport models of both Fig. 1a and d. S and P refer to transportable substrates and their concentrations in the left-hand and right-hand bathing solutions, respectively. E and F refer to the two conformations when the outward-facing binding sites are unoccupied, whereas ES, EP, SEP, FS, FP, and SFP refer to these conformations when the outward-facing sites are occupied by S and/or P.  $K_S$  and  $K_P$  are the equilibrium dissociation constants. The rate constant for the transport event is  $k_{tr}$  and T is the total concentration of pump. The unidirectional flux of S in exchange for P, which of course equals the corresponding flux of P in exchange for S, is given by  $\nu$ ; the solution for  $\nu$  is the same as that previously obtained by Garrahan and Garay² for the model of Fig. 1a. Although it is here assumed that each bathing solution contains only a single type of substrate, introduction of competing substrates results in the same expression for  $\nu$  but with the values of  $K_S$  and  $K_P$  effectively increased. Notice that for the model of Fig. 1d all forms of the pump contain in addition two substrate particles in an occluded state.

lifetime of this form at 0° C. Under the conditions of their Fig. 10, they consider the rate of rephosphorylation of the pump enzyme to be largely determined by the rate of disappearance of this occluded form. The maximum measured rate was obtained with high levels of ATP and had a half-time of about 3 s, from which (on dividing by 1n2) the average lifetime of the occluded form would be some 4–5 s. But perhaps rephosphorylation occurs only after the occluded form disappears, so that this is an overestimate. Post *et al.*<sup>11</sup> found, however, that the phosphorylation reaction by itself is complete in less than 1 s at 0° C. Thus it seems that the occluded form exists for some 3–5 s at 0° C.

To determine for what fraction of the total time the occluded form exists, it is necessary to know the average time for a complete pump cycle. This information can be obtained from the experiments of Kanazawa et al.<sup>12</sup> with the rabbit brain enzyme at 0° C. Under the conditions of their Fig. 3 which are comparable to those of Post et al.<sup>6</sup> the K-stimulated (Na+Mg)-ATPase activity was about 0.11  $\mu$ mol P<sub>i</sub> h<sup>-1</sup> per mg protein. The maximum incorporation of <sup>32</sup>P from <sup>32</sup>P-ATP (Table 2 of ref. 12) was  $1.35 \times 10^{-4}$   $\mu$ mol per mg protein, yielding an average cycle time of 4.4 s. This time may be marginally underestimated due to sub-maximal incorporation of <sup>32</sup>P. Using ouabain binding and the ionic binding of ATP to estimate pump concentrations<sup>13</sup> one obtains turnover

numbers at 37° C averaging some 9,000 min<sup>-1</sup> whereas from Fig. 3 and Table 2 of ref. 12 one calculates a value of 11,000 min<sup>-1</sup>; a correction factor of 1.2 might, therefore, be necessary, giving an average cycle time of up to 5.5 s. Overall, taking the range 3–5 s for the lifetime of the occluded form and 4–5.5 s for the cycle time, it seems that at 0° C the sodium pump spends a very substantial fraction of its time in an occluded form. (This time is presumably spent waiting for the rare thermal event of having sufficient energy to overcome the activation barrier between conformations. The time required for the conformation change itself may be rather short (see, for example, the half time<sup>14</sup> of 14 ms for a photon-induced conformation change of rhodopsin in frog retina at 0° C).)

It would thus seem that the first three models of Fig. 1 must be rejected. We are hesitant, however, to adopt this conclusion unequivocally until either the transport observations are confirmed at 0° C or the occluded form is demonstrated at body temperature, or both these findings are confirmed at some intermediate temperature. Nonetheless, there is some indication that the effect at 0° C of ATP binding to a low affinity site and accelerating the release of an occluded form<sup>6</sup> occurs also at 37° C. At this temperature, binding of ATP to a low affinity site accelerates both the (Na+K)-ATPase activity of the bovine brain enzyme<sup>15</sup> and the K:K exchange across human red blood cell membranes<sup>16</sup>.

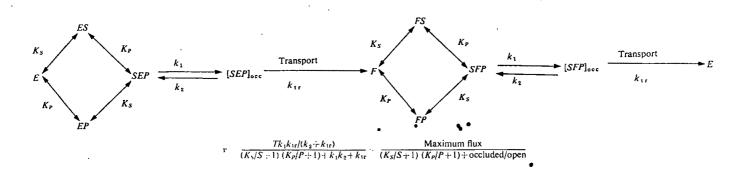

Fig. 3 Kinetic scheme and steady-state solution for the transport models of both Fig. 1b and Fig. 1c. Symbols and comments are as in Fig. 2, with the following additions:  $k_1$  and  $k_2$  are rate constants for reversible non-transporting transitions between open and occluded conformations;  $[SEP]_{occ}$  and  $[SFP]_{occ}$  refer to the occluded doubly bound forms of E and F, respectively; and the ratio 'occluded/open' =  $[SEP]_{occ}/SEP = [SFP]_{occ}/SFP$ . The kinetic solution is that of Garrahan and Garay².

It is encouraging that powerful rejection criteria can be devised on the basis of simultaneity and occlusion. With such criteria one can narrow down the number of possible models for active transport and so reach a clearer understanding of the molecular mechanisms involved.

We thank Dr P. J. Garrahan for his comments on the manuscript.

# Lateral interaction between neural channels sensitive to velocity in the human visual system

MacKay1 has made use of the phenomenon of simultaneous contrast to provide evidence for the existence in the human visual system of neural channels that are sensitive to the density of visual texture. Using the same phenomenon, we have provided comparable evidence for the existence of lateral interaction between channels sensitive to velocity. That such channels do exist is suggested by the preliminary psychophysical observations of Pantle and Sekuler2, who demonstrated a luminance threshold elevation for moving contours that is limited to a range of values around the velocity of the adapting contour.

A 10×6 matrix of dots was generated on the CRT display of a PDP-12 laboratory computer. The ten symbols in each row were programmed to move at a constant velocity in a west-east direction, giving the impression of a continuous stream of dots drifting across a window. A sharp discontinuity (or border) was generated by having the upper set of three rows move at a slower speed than the lower set. Viewed from a distance of 0.8 m the rows and columns of the matrix subtended visual angles of 3° and 1.88° respectively.

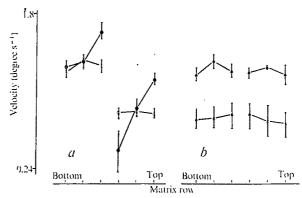

Fig. 1 Perceived velocity of each of the six rows in the matrix of dots, with each point representing the average of three observations. The vertical bars delineate the range of values spanned by the two extreme observations in each case.  $a, \bullet$ , The perceived velocity profile obtained when velocities of 0.30 degree s<sup>-1</sup> and 0.6 degree s<sup>-1</sup> were assigned, respectively, to the upper and lower rows in the matrix. The profile adds confirmation to the illusion reported by several observers; O, with the fast and slow moving rows presented to separate eyes (the left and right respectively) simultaneous contrast does not occur. b, Profiles obtained in control trials in which all six rows were assigned the same velocity, being in the one case 0.6 degree s<sup>-1</sup> ( $\triangle$ ) and in the other, 0.3 degree s<sup>-1</sup>( $\triangle$ ).

With velocities fixed at 0.3 degree s<sup>-1</sup> and 0.6 degree s<sup>-1</sup>, for the upper and lower rows respectively, the authors and several colleagues have experienced an illusion that is consistent with lateral interaction effects. More specifically, the difference in velocity of the rows adjacent to the discontinuity appeared enhanced when compared with the corresponding difference between more outlying rows (for example, the top compared with the bottom row). Perhaps counter-intuitively, the regular columnar organisation seemed to assist in the appreciation of the illusion; the apparent differences in velocity being translated into noticeable deviations from this regularity.

In order to determine more precisely the perceived velocity 'profile' of the matrix, a probe, or comparison row of eight dots was added to one side of the display. Two parameters of this row were made variable: (i) its vertical position could be programmed to coincide with any one of the six rows in the matrix, and (ii) its velocity could be altered by repositioning a smooth lever. By matching the comparison row to each of the six rows of the matrix, an estimate of the perceived velocity profile could be obtained.

One of the authors (P.W.) overcame the initial difficulties that were experienced in trying to both observe the illusion and match the velocity of a selected row and provided the profile illustrated in Fig. 1a. For comparison, the same procedure was followed whilst the dots in all six rows moved with the same velocity, being in the one case 0.6 degree  $\ensuremath{s^{-1}}$  and in the other 0.3 degree s<sup>-1</sup> (Fig. 1b). A comparison of the different profiles highlights the simultaneous contrast character of the illusion. Furthermore, incorporated in Fig. 1a are the results from a condition involving the presentation of the 'fast' and 'slow' moving rows to separate eyes (the left and right respectively). That the illusion does not occur in this condition is consistent with MacKay's results with texture density, and suggests that the lateral inhibitory processes responsible for the illusion reside in the monocular systems, before the point of binocular fusion.

To summarise, the demonstration suggests that the human visual system incorporates channels that are sensitive to velocity and that these channels interact to enhance any discontinuities in this parameter. That there are such channels in the visual systems of cat and monkey is suggested by the discovery of single cells that respond differentially to the speed of a moving stimulus. Such units have appeared in the superior colliculus,

suprasylvian gyrus, and visual area 19 of cat, and in the primary visual cortex of monkey3. The present data may be taken to suggest that with velocity, as with orientation<sup>4</sup>, lateral inhibition effects will be observed at this single cell level.

# Electrophysiology of mammalian spinal cord in vitro

Mammlian spinal cord has often been used in electrophysiological studies where the experiments were carried out exclusively on the spinal cord in situ1. An obvious disadvantage of such experiments is that the concentrations of ions or drugs studied cannot be controlled precisely in the extracellular medium. To overcome that disadvantage, we have developed an isolated spinal cord preparation of the newborn rat.

Wistar rats aged from 0-7 d were used. Under ether anaesthesia, the spinal cord was isolated, hemisected sagittally and placed in a bath perfused with Krebs solution equilibrated with 95% O<sub>2</sub> and 5% CO<sub>2</sub>. The temperature in the bath was kept at 27±1° C. Changes of the membrane potentials of the spinal motoneurones were followed by recording from the ventral root with an extracellular electrode used in two ways. In the first, the ventral root (L3-L5) was led out through a vaseline-sealed slit in the lateral wall of the bath into a paraffin compartment where the root was placed on a Ag-AgCl electrode, which in turn was connected to a preamplifier and an oscilloscope or pen recorder. The bath was grounded through a reference calomel electrode. In the second method, the ventral root was introduced into a glass suction electrode (Fig. 1a). The portion of the ventral root between the spinal cord surface and the orifice of the suction electrode was covered by a mixture of liquid paraffin and vaseline contained in the glass

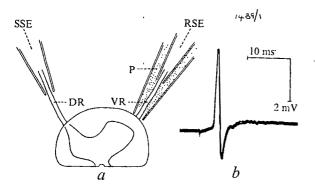

Fig. 1 a, Experimental arrangement. The recording suction electrode (RSE) was connected through a Ag-AgCl electrode to a preamplifier. SS E, stimulating suction electrode; VR, ventral root; DR, dorsal root; P, liquid paraffin. b, Mono- and polysynaptic reflexes induced by a supramaximal volley in L5 dorsal root and recorded from the corresponding ventral root. Positivity upwards.

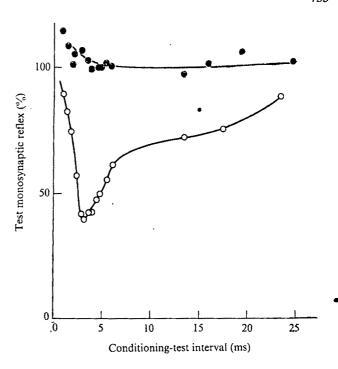

Fig. 2 Postsynaptic inhibition and the effect of Cl deficiency. Test reflex response was induced by a supramaximal volley in L5 dorsal root and was recorded from the corresponding ventral root. Single supramaximal conditioning volley was delivered to L4 dorsal root. Graph shows the amplitudes of the test monosynaptic reflexes expressed as percentages of the unconditioned control and plotted against the conditioning-test intervals, O, in normal Krebs solution; •, in Cl-deficient medium, where 9/10 of Cl ions were replaced by equimolar methylsulphate and methanesulphonate.

cuff. The cuff surrounded the inner suction electrode and was slightly pressed against the surface of the spinal cord. A quite stable d.c. recording was possible in these conditions.

Stimulation of the dorsal root (L3-L5) induced an early sharp spike followed by the later asynchronous waves recorded from the corresponding ventral root (Fig. 1b). The early spike was interpreted as the monosynaptic reflex because its wave form resembled that of monosynaptic reflex observed in the in situ experiments<sup>2</sup> and because the delay time of the spike (about 3 ms in the experiment shown in Fig. 1b) could be explained for the most part by the conduction time in the afferent and efferent pathways3. The preparation was quite stable and a good reflex response could be recorded for at least several hours.

Repetitive stimulation of the dorsal root at 0.3-1 Hz caused a marked decline of the sizes of mono- and polysynaptic reflexes. After tetanic stimulation, a slight increase in the amplitude of monosynaptic reflex (about 130% of the control) was observed. In the experiment illustrated in Fig. 2, L5 dorsal root was stimulated at 0.1 Hz and the reflex response was recorded from the corresponding ventral root. Conditioning stimulation of the adjacent dorsal root (L4), which by itself produced only very slight potential changes in the L5 ventral root, exerted during the following period of several milliseconds a remarkable inhibitory effect on the monosynaptic reflex. Judging from the fact that this inhibition displayed a relatively fast time course and was readily blocked by strychnine (5×10<sup>-6</sup> g ml<sup>-1</sup>), we conclude that it is the postsynaptic inhibition1. When the concentration of chloride ions in the external medium was reduced to one-tenth of the normal, the postsynaptic inhibition was completely abolished (Fig. 2). This strongly indicates that the permeability increase to chloride ions is of predominant importance in this type of inhibition (compare with refs 1, 4 and 5).

The isolated spinal cord preparation described here seems to provide many possibilities for electrophysiological, pharmacological and developmental studies of the spinal cord.

## Excitatory action of hypothalamic substance P on spinal motoneurones of newborn rats

It is generally believed that the primary afferent fibres constituting the spinal dorsal roots, form excitatory synapses with the neurones in the spinal cord and the brain stem<sup>1</sup>. Several substances have been considered as the neurotransmitters of the primary afferent neurones<sup>1-5</sup>. We have found that an undecapeptide, substance P, which has been isolated from bovine hypothalamus<sup>6,7</sup>, exists in the dorsal root of bovine spinal nerve in an amount 10-30 times larger than that in the ventral root<sup>8,9</sup>, and that this peptide exerts a potent excitatory action on the spinal motoneurones of the frog<sup>8,10</sup>.

These findings led us to postulate a hypothesis that hypothalamic.substance P is a neurotransmitter of the primary afferent neurones and, to explore this hypothesis further, we examined the effect of hypothalamic substance P on the neurones of the mammalian spinal cord. The isolated spinal cord preparation of the newborn rat is suitable for this purpose because substances can be applied by adding to the perfusion

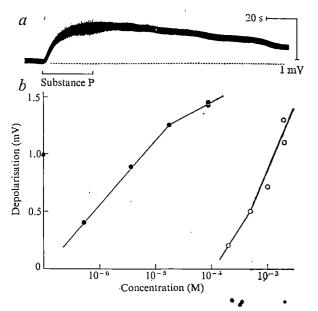

Fig. 1 a, The potential recorded from the L4 ventral root of an isolated spinal cord of a newborn rat. Hypothalamic substance P (9×10<sup>-5</sup> M) was bath-applied during the period indicated. Depolarisation is upwards; dotted line indicates the control level. b, Dose-response curves of hypothalamic substance P ( ) and L-glutamate ( ), obtained in another preparation. Ordinate, amplitude of the induced depolarisation recorded from L4 ventral root; abscissa, molar concentration of the applied drugs on a logarithmic scale.

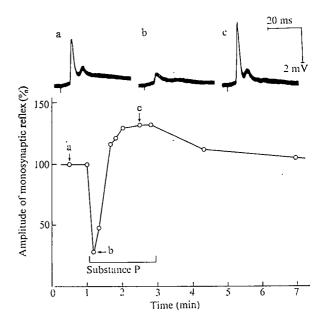

Fig. 2 Effect of hypothalamic substance P  $(3 \times 10^{-5} \text{ M})$  on the spinal reflex. L4 dorsal root was stimulated supramaximally at 0.1 Hz and the reflex responses were recorded from the corresponding ventral root. Graph shows the amplitude of the monosynaptic reflex plotted over time. Substance P was bath-applied during the period indicated in the graph. Upper oscillographic traces show sample records at the times indicated by arrows in the lower graph.

fluid in controlled concentrations, which enables us to make an exact estimate of the relative potencies. The method of recording the electrical activities generated in the motoneurones was the same as described in the accompanying paper<sup>11</sup>.

When Krebs solution in the bath was replaced by the solution containing synthetic hypothalamic substance P, a depolarisation accompanied by the spike discharges of spinal motoneurones was recorded from the ventral root (Fig. 1a). After the bath was washed out with Krebs solution, the recovery took place with a slow time course of a few minutes. L-Glutamic acid of relatively high concentrations induced similar depolarisation and spike discharges but the time course of the response was faster than that of substance P. In Fig. 1b, the relationship between log molar concentration and the induced depolarisation was plotted for both hypothalamic substance P and L-glutamate. From the comparison of the dose-response curves at the level of 1 mV potential change, the potency of the depolarising action of substance P was estimated to be about 200 times higher than that of L-glutamate which is regarded as a leading candidate for the excitatory transmitter in the spinal cord<sup>2</sup>.

To find out whether hypothalamic substance P causes the depolarisation by directly acting on the motoneurones or by a trans-synaptic mechanism, the effect of the peptide was re-examined after the intraspinal synaptic transmission was blocked in a low-Ca and high-Mg solution. When the preparation was soaked in a modified Krebs solution containing 0.4 mM Ca and 7 mM Mg, the ventral root reflex evoked by dorsal root stimulation was completely abolished. At this stage the depolarisation induced by substance P was as large as that in normal Krebs solution, suggesting that the peptide has a direct excitatory action on the spinal motoneurones10.

Figure 2 shows the effect of hypothalamic substance P on the spinal reflex. First, the peptide induced a transient inhibition followed by a potentiation of the monosynaptic reflex. The first inhibitory effect of substance P may be due to the activation of the GABA-operated inhibitory mechanism because this inhibition was almost completely abolished after the treatment of the preparation with picrotoxin (10<sup>-5</sup> g ml<sup>-1</sup>). The second facilitatory effect, on the other hand, can be explained by the depolarisation of the motoneurones.

Thus the present results give further support to the hypothesis that hypothalamic substance P may serve as an excitatory transmitter of the primary afferent neurones in the spinal cord.

## A new type of hereditary persistence of foetal haemoglobin: is a diffusible factor regulating y-chain synthesis?

PERSISTENCE of foetal haemoglobin synthesis into adult life produces a condition known as hereditary persistence of foetal haemoglobin (HPFH). Different types of HPFH have been described but the precise molecular mechanism(s) responsible for them has not been clarified. Several genetic hypotheses have been proposed, of which the most widely accepted is that of a deletion in the δβ complex; this would agree with the fact that both the gene(s) for HPFH (so far described) and the β-structural locus behave as alleles. We have studied a new type of HPFH in a negro family, the gene for which does not behave as an allele of the δβ complex, and have therefore proposed a genetic interpretation for this condition.

The index case was found during the course of a systematic re-examination of patients previously diagnosed on clinical grounds as cases of sickle-cell anaemia. The pedigree and the haematological data of the family are shown in Fig. 1 and Table 1. The pedigree shows that a βs, a βthal and a gene for the persistence of foetal haemoglobin at approximately 5% level, are segregating in this family. While  $\beta^s$  and  $\beta^{that}$  behave as usual (they are found separately in I<sub>1</sub> and I<sub>2</sub>, together in II<sub>1</sub>,

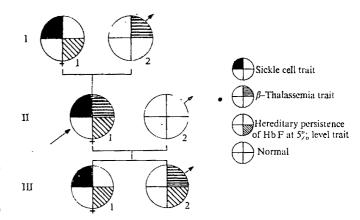

Fig. 1 Pedigree of the family AMR. The arrow indicates the proposita.

and segregate again in III, and III, the mode of transmission. of the gene for HPFH is very strange. In fact, II<sub>1</sub> who has the responsible gene in a single dose (her father has normal levels of foetal haemoglobin (HbF)), transmits it together with the βs (both genes received from I<sub>1</sub>) and the β<sup>thal</sup>. The phenotype of I<sub>1</sub> also seems to be anomalous: an inherited form of persistence of HbF coexists with a normal HbA/HbS ratio (see Table 1), although in every form of this condition so far described, there has always been total or partial differential depression of the β gene in the cis form, with respect to the HPFH mutation<sup>1</sup>.

This is the first clear example in which a gene causing persistence of HbF does not behave as an allele of the δβ complex, as indicated by the fact that both \( \beta^s \) and HPFH sites, together in the gamete transmitted from I<sub>1</sub> to II<sub>1</sub>, were present in the gamete transmitted from II<sub>1</sub> to III<sub>1</sub>. Furthermore, only the HPFH site was transmitted from II1 to III2: in this case the locus for the persistence of HbF and that of  $\beta^{that}$  previously separated, must have travelled together in the gamete which II<sub>1</sub> has transmitted to III<sub>2</sub>. This individual carries both the genes for \( \beta^{that} \) and for HPFH, as indicated by the high levels of HbA2 and HbF. The latter finding cannot be explained by the variability of HbF in βthat heterozygotes, because it has been shown that HbF levels show intrafamilial segregation in β<sup>thal</sup> (ref. 9); and the grandfather of III<sub>2</sub>, who transmits the high-A<sub>2</sub> β<sup>thal</sup> gene, only shows 0.6% HbF. Moreover, the gene causing persistence of HbF does not alter the HbA/HbS ratio. Each of these two findings suggests that the site of mutation of the persistence of HbF in this family is located in a gene different from the classical HPFH gene.

The haematological, biochemical and genetic data of this family can be explained by the following assumptions: (1) The abnormality results from persistent γ-chain synthesis from one of the  $\gamma$ -chain loci in  $I_1$  which passes on to  $III_1$  through  $II_1$ . (2) The coexistence of both genes for β<sup>that</sup> and HPFH in III<sub>2</sub>

+. Slightly increased; ++, increased; +++, very increased. Haematological indexes and osmotic fragility were obtained by standard methods<sup>2,3</sup>. Red blood cells (RBC) counts were performed in an Automatic Cell Counter (TOA Microcell Counter, Mod. CC-1002). Haemoglobin electrophoresis was performed according to the method of Smithies. An electrophoretic technique was also used for the quantitation of HbA and HbS. HbA2 was quantitated by the chromatography method of Berninis, and HbF by the alkali denaturation method of Betker. The amount of serum iron was determined by the sulphonated bathophenanthroline method8.

is the consequence of a cross-over between the  $\gamma$  and  $\beta$  loci, a highly improbable event because of the linkage between the two loci<sup>10,11</sup>. In fact, this would be the first example of a recombination between HPFH and βs sites. (3) This hypothetical mutation, producing persistence of HbF, does not affect the expression of the β-structural gene in the cis form.

It is evident that many assumptions have to be made to fit all the data within the classical scheme. On the other hand, all the findings are to be expected assuming that the mutation under discussion is located in a locus which does not affect γ-chain expression by an intrachromosomal interaction. It is tempting to suggest that there exists a locus which affects the  $\gamma$ -chain expression via a diffusible substance. This would be the first example in mammals of a regulatory mechanism affecting the synthesis of a polypeptide chain by a diffusible substance.

We thank Drs Guido Modiano and Luciano Terrenato for discussions and cooperation in the preparation of the manuscript, and A. Hernandez for technical assistance.

# Sulphydryl groups as a new molecular probe at the $\alpha_1$ $\beta_1$ interface in haemoglobin using Fourier transform infrared spectroscopy

THE haemoglobin molecule consists of a pair of subunits, each of which is made up of two different haem-bearing polypeptide chains,  $\alpha$  and  $\beta$ . The contacts between the two  $\alpha\beta$  subunit pairs are not covalent and constitute the  $\alpha_1\beta_2$  (and  $\alpha_2\beta_1$ ) interface. Symmetrical dissociation of the haemoglobin molecule occurs relatively easily at this interface. Large changes in the  $\alpha_1\beta_2$ contacts occur² as the molecule switches from the T to the R conformation during ligand binding3.

The association of the  $\alpha_1\beta_1$  (and  $\alpha_2\beta_2$ ) contact is much stronger. Although this contact is formed largely by nonpolar van der Waals interactions, asymmetrical dissociation along the  $\alpha_1\beta_1$  interface is more difficult to achieve and little change occurs here during ligand binding<sup>2</sup>. Reactions of the sulphydryl (SH) groups of cysteinyl residues α-104 (G11) and especially  $\beta$ -112 (G14), located at the  $\alpha_1\beta_1$  interface, are very useful in dissociating the αβ subunit4.5.

These residues may also be involved in intracellular haemoglobin denaturation occurring in thalassaemia and unstable haemoglobinopathies as well as in interaction of denatured haemoglobin with cell membranes. In spite of its importance to haemoglobin structure and stability, the  $\alpha_1\beta_1$  interface and its hidden SH groups have remained inaccessible to available

We report here the first observation of infrared absorption bands due to SH groups in a native protein. The observed infra-

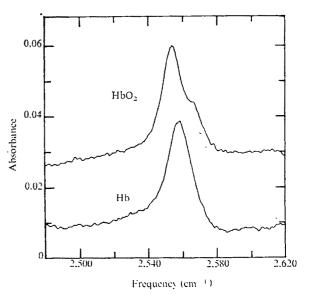

Fig. 1 Infrared spectra of 17 mM (haem) human oxyhaemoglobin and deoxyhaemoglobin against 16 mM bovine carboxyhaemoglobin and deoxyhaemoglobin, respectively. Single beam spectra of human haemoglobin samples were taken in a cell with a 0.2 mm optical path and CaF<sub>2</sub> windows using a Digilab Model FTS-14D interferometer equipped with a liquid nitrogen-cooled InSb detector. Four sets of 64 coherently added interferograms were independently subjected to Fourier transformation and were, in turn, co-added to yield a digital single beam spectrum at 2 cm resolution. This was initially compared with a single spectrum of air to produce an absorbance spectrum of the sample. A similarly obtained digital absorbance spectrum of H<sub>2</sub>O was then subtracted from the sample spectrum. The water content of the samples was determined from a near infrared absorption band of H<sub>2</sub>O at 1.92 μm. Bovine haemoglobin spectra were treated similarly and subtracted from the human haemoglobin spectra. Haemoglobin solutions were buffered to pH 7.1 bisTris and were 0.1 M in chloride.

red absorption bands are the result of S-H stretching vibrations of cysteine residues at the  $\alpha_1\beta_1$  interface ( $\alpha$ -104 (G-11) and β-112 (G-14)) of native human haemoglobin A. Centre frequencies and absorption intensities of these SH groups provide structural information about haemoglobin in aqueous solution that has been available in no other way.

The absorption bands due to cysteine SH groups at the  $\alpha$ -104 (G-11) and β-112 (G-14) positions of human oxyhaemoglobin and deoxyhaemoglobin, respectively, are shown in Fig. 1. These were measured with Fourier transform infrared (FTIR) interferometry (with a Digilab Model FTS-14 Fourier transform spectrometer), and are corrected for absorptions due to water and to protein by subtraction of the appropriate spectrum of bovine haemoglobin, which contains cysteine only at the  $\beta$ -93 position. The latter residue is predicted to have only a very weak, broad absorption band that is not observed in our conditions. The use of bovine haemoglobin as reference assures that only cysteine SH groups at the  $\alpha$ -104 and  $\beta$ -112 positions in human haemoglobin will be observed. Assignment (J.O.A., G.H.B., and P.A.B., unpublished) of these absorption bands to S-H stretching vibrations is based on: first, comparison with small molecule thiols; second, loss of the absorption band at alkaline pH; and third, observation of a pair of bands with a similar absorption envelope near 1,855 cm<sup>-1</sup> in D<sub>2</sub>O but not in  $H_2O$ , that have a calculated isotopic frequency ratio  $(v^*/v)$ equal to 0.7268, which is virtually identical to the corresponding values calculated from the data<sup>8</sup> reported for methanethiol vapour (0.7267) and liquid (0.7270).

The spectrum of human oxyhaemoglobin SH groups (Fig. 1) clearly contains two overlapping bands of differing intensities. Quantitative band shape analysis shows that the apparently more symmetrical deoxyhaemoglobin SH spectrum is also composed of two overlapping bands. Horse and pig haemoglobins contain cysteine residues at only the α-104 and β-93 positions7. Their oxyhaemoglobin spectra, when compared with

bovine haemoglobin (β-93 cys), show only a single symmetrical absorption band of similar frequency and intensity to the lower frequency, more intense, SH absorption band of human haemoglobin. A band corresponding to the lower intensity SH shoulder from human oxyhaemoglobin is not present in spectra from horse or pig. We therefore assign the band at 2,553.8 cm<sup>-1</sup> to v(SH) of the  $\alpha$ -104 cysteine in human oxyhaemoglobin, and the shoulder due to a band at 2567 cm<sup>-1</sup> to v(SH) of the  $\beta$ -112 cysteine. Corresponding bands are observed at 2,557.0 cm<sup>-1</sup> and 2,564 cm<sup>-1</sup> in human deoxyhaemoglobin. These frequencies are sensitive to the state of ligation of haemoglobin, and differ in the order HbCO < HbO<sub>2</sub> < HbCN < Hb<sup>+</sup>  $\ll$  Hb, for the α-104 v(SH) (J.O.A., G.H.B., and P.A.B., unpublished).

The reasons for the sensitivity of these sulphydryl groups to small changes in molecular structure may be understood by consideration of the observed absorption intensities (Table 1). Monomeric thiols absorb very weakly in the infrared unless they are polarised by molecular interactions such as H bonding9. Thus, H bonding by solvent water produces about three times the integrated intensity observed in CCl<sub>4</sub>, and acetone produces a further threefold increase in intensity. The integrated intensity of propanethiol in acetone<sup>10</sup> is somewhat less that due to the β-112 cysteine SH, but less than one fourth of that due to the α-104 cysteine SH. We therefore propose that both of the SH groups at the  $\alpha_1\beta_1$  interface in haemoglobin must be strongly H bonded, probably to a peptide carbonyl of the fourth residue back in the G helix. Such an H bond seems consistent with Perutz' suggestion that certain serine residues may form similar H bonds<sup>11</sup>. This possibility was tested by construction of molecular models of the G helices for horse oxyhaemoglobin (Labquip Co., Caversham, UK) from coordinates attributed to

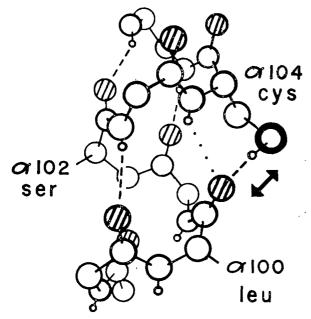

Fig. 2 Drawing of the a chain G helix of horse oxyhaemoglobin from α-98 (G-5) to α-105 (G-12), prepared from a photograph of a molecular model. The amino acid side chains are not included except for that of a-104 (G-11) cysteine. The oxygen atoms are shaded and the sulphur atom is in bold face.

Perutz. The G helix of horse  $\beta$  chain contains no cysteine, and the amide NH groups all seem to be fairly well aligned with corresponding amide carbonyl groups four residues back. The same observation is made for the G helix of the horse a chain except for the amide carbonyl of  $\alpha\text{-}100$  (G-7 leu), which seems to stick out sharply from the helix (Fig. 2). This carbonyl is in a very favourable position to form a strong H bond with the SH group of the α-104 (G-11) cysteine, which would satisfy the infrared intensity requirements. We predict that a somewhat lesser distortion of the human  $\beta$  chain G helix may be found, which would permit an amide carbonyl at β-108 or β-109 to form a somewhat weaker H bond with the  $\beta$ -112 cysteine SH, which may be shared with an amide NH group of β-112 or  $\beta$ -113, respectively. A weaker H bonding of the  $\beta$ -112 cysteine SH group would agree with the weaker infrared absorption intensity and higher frequency of the band assigned to this group (Fig. 3). Polarisation and rotational fixation of the  $\beta$ -112 SH by H bonding may partially account for the greater reactivity with iodoacetate of the  $\beta\text{-}112$  as compared to the  $\beta\text{-}93$ sulphydryl in isolated human haemoglobin \beta chains observed by Neer12.

Fig. 3 Proposed H bonding for the  $\alpha$ -104 (G-11) and  $\beta$ -112 (G-14) cysteine SH groups in human haemoglobin.

This model can account qualitatively for the observed sensitivity of v(SH) to differences in the state of haem ligation. Change in quaternary structure upon ligation results in a relative displacement of atoms at the  $\alpha_1\beta_1$  contact by about 1 Å (ref. 2). The contribution of altered van der Waals contacts to v(SH), however, should be small unless there is an alteration of polar group association with the sulphydryls. Alternatively, changes in tertiary structure may be responsible. Slight bending of the G helix would be geometrically amplified to change the S-H .. O=C hydrogen bond distance (Fig. 2, arrow), or a slight rotation of the α-100 peptide carbonyl could cause a change in the strength of the hydrogen bond association. Although these possibilities remain to be tested, Fourier transform infrared spectroscopy of haemoglobin sulphydryl groups clearly provides a sensitive molecular probe for the observation of structural changes in the  $\alpha_1\beta_1$  interface region resulting from tertiary

#### NMR evidence for tertiary structure base pair in E. coli tRNA involving S<sup>4</sup>U<sub>2</sub>

In previous nuclear magnetic resonance (NMR) studies of tRNA we observed anomalously low field resonances (14.5-15.0 p.p.m. downfield from the usual standard 2,2-dimethylsilapentane-5-sulphonate (DSS)) in the spectra of many, but not all, Escherichia coli tRNA1-3 but yeast tRNA we examined never exhibited such resonances1,2. The fact that approximately 60% of the E. coli tRNA are class I and have a 4-thiouridine (S4U) residue at position 8 (refs 4 and 5), whereas yeast tRNA do not, raised the possibility that the anomalous low field resonances in E. coli tRNA might be due to ring NH protons of S'U8 in a tertiary structure base pair.

To test this possibility, NMR spectra of S'U and U mononucleosides were compared in dimethylsulphoxide (DMSO) and we found that the ring NH proton of U was at 11.5 p.p.m. (ref. 6) whereas the corresponding resonance of S'U was at 12.6 p.p.m. (K.L.W. and D.R.K., unpublished). Assuming comparable hydrogen bond strengths, these model system studies suggested that the ring NH proton of an S'U-A base pair would be located further downfield than the corresponding resonance of an AU base pair. As resonances from AU base pairs can be located as far downfield as 14.5 p.p.m. (refs 1-3), these observations prompted us to re-examine the assignment of the anomalous low field resonances in E. coli tRNA. For this study we chose to work with unfractionated tRNA to determine whether or not base pairing with S'U<sub>8</sub> is a common feature in E. coli tRNA. As we shall show, a tertiary structure base pair involving S'U<sub>8</sub> is responsible for the anomalous low field resonances in the NMR spectra of E. coli tRNA.

Unfractionated E. coli tRNA was obtained from Plenum Scientific (Lot no. 73042). Three different procedures were used to convert S'U to U, including IO<sub>3</sub> oxidation (K.L.W. and D.R.K., unpublished), photo-oxidation7,8 and cyanogen bromide treatment<sup>9,10</sup>. The conversion of the S<sup>4</sup>U to U was monitored by following the disappearance of the S'U absorption spectrum and in each case at least 90% of the S'U residues were converted. NMR samples were prepared free of chemical reagents and then dialysed against solutions containing appropriate amounts of Mg2+, cacodylate and NaCl. A typical sample contained ~25 mg ml-1 of tRNA, 0.1 M NaCl, 10 mM Mg and 10 mM cacodylate buffer, pH 7. NMR spectra were obtained with a Varian HR 300 spectrometer operated in the field sweep mode. All spectra were extensively (1-2 h) signal averaged using a Nicolet 1020A signal averager. The low field NMR spectrum of the untreated E. coli tRNA is shown in Fig. 1 along with the spectra of the chemically modified samples. All spectra were taken at 25° C.

As expected on the basis of our earlier examination of several pure E. coli tRNA species, unfractionated E. coli tRNA exhibits a broad, rather weak resonance located around 14.8 p.p.m. with only ~0.025 times the intensity of the resonances located between 11.5 and 14.5 p.p.m. Resonances in the 14.5-11.5 p.p.m. region have previously been assigned to the ring NH protons of AU or GC Watson-Crick base pairs (one resonance per base pair)1-3

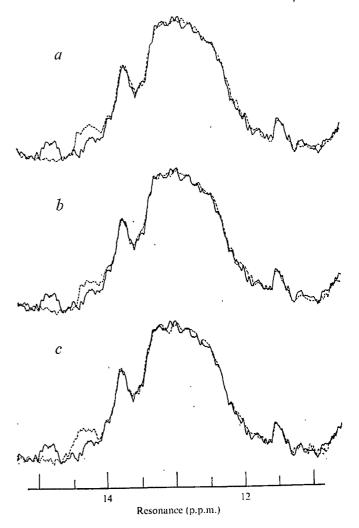

Fig. 1 A comparison of the 300 MHz proton NMR spectra of unfractionated E. coli tRNA before (——) and after (——) chemical conversion of S<sup>4</sup>U to U. Spectra were obtained at 25° C and the positions of the resonances are in p.p.m. downfield from DSS. Additional experimental details are given in the text. Three differential chemical procedures -) and after were used, including a, photo-oxidation; b, cyanogen bromide treatment; and c,  $\mathrm{IO_3}^-$  oxidation. As these comcyanogen parisons demonstrate, the only major changes in the spectra occur in the 14.8 and 14.3 p.p.m. regions of the spectra. All other features in the spectrum remain virtually unchanged.

and integration of these spectra indicates there are an average of 20±2 resonances per tRNA<sup>1-3</sup>. Thus, the intensity in the 14.8 p.p.m. region corresponds approximately to ~0.5 proton (base pair) per molecule. This number is consistent with our attribution of the 14.8 p.p.m. resonance to S'U as about 60% of the E. coli tRNA are class I and have an S'U residue at position 8 (refs 4 and 5).

To prove that S'U residues are responsible for the anomalous low field resonances three different chemical procedures were used to convert S'U to U. The effect of each of these on the low field NMR spectrum is shown in Fig. 1. In each case the S⁴U→U conversion causes the loss of the 14.8 p.p.m. resonance and the appearance of a new resonance at around 14.3 p.p.m. On the basis of these observations we conclude that the anomalous 14.8 p.p.m. resonance in E. coli tRNA is due to a tertiary structure base pair in which S'U8 is hydrogen bonded with another base located elsewhere in the molecule. Consideration of the low field position of the resonance (before and after conversion to U), and the relative strengths of in-plane ring current shifts from G and A suggest that an adenine is the other base paired with S'U<sub>8</sub>.

The following observations suggest that A at position 14 is the one paired with S'U8. It has been demonstrated that

S'Us can be photochemically crosslinked with C13 in several different E. coli species without significantly affecting the biological activity11,12. As expected, we also observed that photocrosslinking  $S^4U_8$  and  $C_{13}$  resulted in loss of the 14.8 p.p.m. resonance (K.L.W., and D.R.K., unpublished). Furthermore, conversion of S'U to U has little effect on the biological activity of the E. coli tRNA (refs 8 and 10). Taken together, these results indicate that in a biochemically active conformation the arms of the cloverleaf are folded with S'Us located close to C13 and therefore also close to the A residue which is always present at position 14 (refs 4 and 5). On this basis, the 14.8 p.p.m. resonance is assigned to a tertiary structure base pair between S'U8 and A<sub>14</sub>. The formation of such a base pair was proposed some time ago by Levitt's on essentially the same grounds, but this is the first experimental evidence that S'U8 is actually involved in a tertiary structure base pair. Recent X-ray diffraction data show that A14 and U8 are close together in yeast tRNA Phe crystals, but the resolution is not adequate to show whether they are actually hydrogen bonded<sup>13,14</sup>. As a new resonance appears in the E. coli tRNA spectrum at 14.3 p.p.m. when  $S^4U_8$  is converted to U<sub>8</sub>, there should be a similar resonance from a tertiary structure A-U<sub>8</sub> base pair in yeast tRNA. Re-examination of previously published spectra indicates that this is probably true<sup>1-3</sup>.

Based on Leonard's structural studies of the S'U-C photodimer<sup>15,16</sup> and his model for the arrangement of S'U<sub>8</sub> with respect to C<sub>13</sub> in tRNA (ref. 17), and previous NMR studies of yeast tRNAPhe which indicates that A14 is stacked on GC<sub>13</sub> (ref. 18) we have to conclude that the S'U<sub>8</sub>-A<sub>14</sub> base pair is not Watson-Crick. If a few additional tertiary structure base pairs can be identified, then it may be possible to determine the complete folding of tRNA molecules in solution, particularly when this information is combined with the results of rare earth metal binding studies18,20. Because the A-S'U(U) tertiary structure base pair is not part of a regular double helix it should be very sensitive to solvent conditions (salt, Mg2+, temperature) which are known to stabilise or destabilise the folding of tRNA. A detailed re-examination of the NMR spectra of some pure species and further work on chemical modifications is currently under investigation.

We thank the United States Public Health Service and the National Science Foundation for grants. ## Possible role of DNA synthesis in formation of sister chromatid exchanges

As there is now evidence that an eukaryote chromosome is composed of a single molecule of double-stranded DNA1,2, sister chromatid exchanges (SCEs) detectable in mitotic chromosomes of higher organisms can be regarded as a kind of recombination between two homologous DNA duplexes. The SCE formation is readily enhanced by exogenous agents such as ultraviolet light and chemical mutagens and seems to be closely related to post-replicational repair process in mammalian cells3. Precise knowledge about the time and sites of the SCE formation might help greatly to understand the mechanism underlying this phenomenon and its biological significance. Previous attempts3 to pinpoint cellular phases in which this recombination process is initiated have been hampered by the usage of 3H-thymidine which, although indispensable for the demarcation of sister chromatids, would cause strand scissions at any cellular phases.

A chromatid consisting of DNA substituted with 5-bromodeoxyuridine (BUdR) can be clearly distinguished from one containing no BUdR using fluorescence staining techniques3-5, and visible light causes strand breaks in BUdR-substituted DNA regions<sup>6,7</sup>. Taking advantage of these facts I here present circumstantial evidence that the site of the SCE formation is strictly limited to DNA portions which are undergoing or just have completed replication.

Chinese hamster cells growing exponentially, D-63, were labelled with BUdR at various concentrations for 5 h in the dark, washed and incubated further for 21 h in fresh medium containing 10 µg ml<sup>-1</sup> thymidine, and then fixed for chromosome preparation following 1 h pretreatment of cells with 0.05 µg ml<sup>-1</sup> colcemid. The slides were stained with 0.125 mg ml-1 acridine orange3. Most metaphase cells were in the second post-labelling mitosis (generation time; 16th). Visible light illumination to cells labelled with BUdR was carried out at room temperature during the second post-labelling cell cycle at various time intervals from collection. The light source was a 20 W blue fluorescent light bulb (National) which emitted no ultraviolet light. Culture dishes containing 2 mm deep medium were placed at a distance of 5 cm from the bulb. The energy flux of the incident light in these conditions has not been determined. DNA synthetic activity of cells was determined autoradiographically in BUdR-substituted duplicate cultures by labelling cells with 3H-thymidine during the period of visible illumination.

Effects of the concentration of BUdR and visible illumination on the frequency of SCEs are shown in Fig. 1 and Table 1. In non-illuminated contröls, the frequency of SCEs remained unchanged at BUdR concentrations 0.25-2.5 µg ml-1. At higher concentrations it increased with increasing concentration. Visible illumination readily provoked SCEs in cells labelled with 1.0 µg ml<sup>-1</sup> BUdR. In the following experiments,

Fig. 1 Chinese hamster chromosomes stained with acridine orange. The cell was labelled with BUdR (1.0 μg ml<sup>-1</sup>) for 5 h and illuminated with visible light in the second post-labelling cell cycle for 20 min at 8 h before collection (× 1,680).

cells were labelled exclusively with 1.0  $\mu g$  ml  $^{-1}$  BUdR and received 20 min visible illumination.

Figure 2 shows the time relationship of DNA synthetic activity of cells and the incidence of SCEs in No. 1 chromosomes. It is clear that the formation of SCEs was enhanced only when visible illumination was carried out in the S phase. As for the failure to induce SCEs in G2, there may be a possibility that the G2 chromatin might be resistant to the photolysis by visible light because of its condensed state and protection by chromosomal proteins. I thought this unlikely, however, as chromosomal aberrations were readily induced in cells illuminated with visible light at G2. Without illumination, the frequency of chromatid breaks and achromatic lesions was about 0.03 per cell whereas in cells illuminated at 2 h before collection, it was 0.28 per cell.

The parallel between the increase in SCE frequency and in DNA synthetic activity was also found in the X chromosome (Fig. 3a). The X of Chinese hamster is a biarmed chromosome, the short arm replicates in the earlier part of S while the long arm in the later part of S. The X as a whole starts DNA synthesis about 2 h behind the other chromosome complements such as No. 1 chromosomes (Figs 2 and 3a). The increase in the SCE frequency over the control level was detected only when this particular chromosome was under replication. SCEs induced by visible illumination were observed exclusively

Table 1 Frequencies of SCEs in BUdR-labelled cells with or without visible illumination during the second post-labelling cell cycle

and 50 chromosomes each in visible illuminated cells.

in the short arm in the earlier part of S whereas in the long arm in the later part of S. Figure 3b shows the ratio of the long arm to the whole X with respects to SCE frequency and DNA synthetic activity. The time when the curves for SCE ratio (Fig. 3b, A and B) crosses the control line is not appreciably different from the time when the ratio for DNA synthetic activity cross the average line; that is, when the majority of DNA-synthesising sites moved from the short arm to the long arm. This seems to indicate that strand breaks responsible for the initiation of recombination process might be those induced in DNA regions which are replicating or have just completed replication. The majority of breaks caused by visible light in BUdR-substituted strands may be repaired without strand exchanges between chromatids7. It is uncertain whether the concurrence of the SCE formation with DNA replication is due to a direct involvement of replication forks in the recombination process or due merely to geometrical constraint in terms of the possibility of the interaction of two broken ends; separation of duplicated DNA strands and their subsequent binding with chromosomal proteins might reduce greatly such a probability.

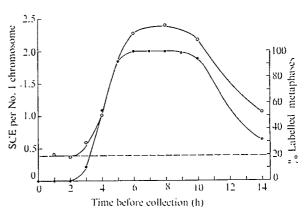

Fig. 2 The formation of SCEs in No. 1 chromosomes in relation to DNA synthetic activity of cells.  $\bullet$ , DNA synthetic activity is expressed as the % labelled metaphases. BUdR-substituted cells were labelled with \*H-thymidine (0.6  $\mu$ Ci ml $^{-1}$ , specific activity 12.1 Ci mol $^{-1}$ ) for 20 min during the second cell cycle while they were being illuminated with visible light. O, The SCE frequency was scored in cultures untreated with \*H-thymidine. ---, Non-illuminated control.

The labelling procedure used here was such that only one of four strands in a metaphase chromosome contained BUdR. As the target of the photolysis by visible light is BUdR-substituted DNA portions, the results obtained in this work may seem to imply that a single break in a BUdR-substituted parental strand is sufficient to initiate a process of the SCE formation. The following alternatives cannot be precluded, however. First, a small amount of BUdR, which is undetectable by the present technique, would be incorporated into other three strands probably at the time of repair of spontaneous DNA lesions<sup>8</sup>, thereby providing two breaks upon visible illumination to initiate the recombination process. Second, visible illumination might cause strand breaks also in DNA unsubstituted with BUdR, though far less efficiently than in BUdR-substituted DNA6, and the SCE formation is initiated by two breaks each made in sister chromatids. As to the latter possibility, it was confirmed that at least DNA lesions detectable as chromosomal aberrations were not caused by visible illumination in cells untreated with BUdR: The number of breaks in cells illuminated with visible light 6 h before collection was found to be 0.06 per cell. This value was not significantly different from that obtained in non-illuminated controls (0.02 chromotid breaks per cell).

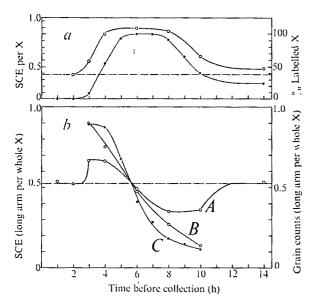

Fig. 3 The formation of SCEs and DNA synthetic activity in the X chromosome examined in the same samples as those used in Fig. 2a, time relationship of the enhancement of the SCE formation by visible light (O) and DNA synthetic activity (O) of the X chromosome. b, Ratios for the SCE frequency and DNA synthetic activity in the long arm of the X to those in the whole X. The SCE ratio in non-illuminated control was 0.524, whereas the average ratio for DNA synthetic activity was 0.526. The latter value was obtained by dividing the sum of the number of silver grains scored on the long arm in each sample by that on the whole X. Both ratios are indicated as a single broken line. Curve A shows the SCE ratio determined based on the net frequency of SCEs and curve B that based on the fraction of SCEs solely due to visible light illumination. Curve C indicates the ratio for DNA synthetic activity assessed by grain count.

The simplest and most attractive models for recombination presume two strand breaks as an initial step which is then followed by a heteroduplex formation by two broken ends thus derived9-11. A speculation that a discontinuously replicating DNA piece at the replication fork might provide a pairing mate to a broken end in a BUdR-substituted strand seems to be attractive and awaits more detailed studies in this respect.

## Localisation of 5S ribosomal RNA genes on human chromosome 1

We have used in situ hybridisation to locate a major 5S RNA locus near the end of the long arm of chromosome 1 of man. This information represents a step towards the understanding of the synthesis, assembly and regulation of ribosomes. The 5S RNA molecule is associated with the larger ribosomal particle in both higher and lower organisms and is required for ribosome function. Ribosomal RNA-18S and 28S-is synthesised at the nucleolar organiser regions on the chromosomes of the D and G groups1. Genes coding for 5S RNA have been located in Drosophila2, Xenopus3 and several other organisms4, and our data now confirm preliminary reports5.6 that placed the 5S genes on chromosome 1 of man. We also suggest a mechanism for positioning the 5S genes near nucleoli at interphase.

Hybridisation experiments with human DNA on nitrocellulose filters have shown that DNA from the largest chromosomes has more 5S RNA genes than that from chromosomes in the other three size classes7. We have used the recently reported method for localising 5S genes more precisely by RNA:DNA annealing to metaphase figures, using high specific activity 5S RNA labelled with 125I. The 5S RNA was isolated from polysomes of HeLa cells and purified by preparative gel electrophoresis. After iodination8 the RNA was repurified on another column (DEAE cellulose), dialysed extensively against water and lyophilised. This 5S RNA (specific activity about  $2 \times 10^8$  d.p.m.  $\mu g^{-1}$ ) was reconstituted in  $4 \times$  SSC (0.15 M NaCl, 0.015 M sodium citrate) at pH 6.0 at a concentration of 2 µg ml<sup>-1</sup>. The nucleotide sequence of this HeLa 5S RNA has been determined and it was at least 90% pure 5S RNA.

Slides were prepared from cultured leukocytes taken from the peripheral blood of two individuals. We used standard methods involving methanol-acetic acid fixation. Just before hybridisation the chromosomal DNA on slides was denatured in 0.2 N HCl for 20 min. at room temperature, chilled immediately in 0° C 2×SSC, dehydrated in ethanol and air dried. The reconstituted 5S RNA solution was diluted with an equal volume of formamide and used for annealing experiments with chromosome preparations. Background radioactivity and nonspecific binding are reduced considerably if 1-4 mg of commercial Esherichia coli tRNA or yeast 4S and 5S RNA is added to 1 ml of hybridisation mixture. Other details of the procedure have been described8. Autoradiographs were prepared using a 1:1 (w/w) dilution of Kodak NTB with distilled water, exposed for 2 months, developed by standard methods and stained with Giemsa in Sorenson's buffer at pH 7.0.

Fig. 1 Autoradiographs of human chromosomes of the A group hybridised in situ with <sup>125</sup>I-5S RNA. The horizontal lines indicate sets of A group chromosomes from six different cells. The diagrammatic chromosomes agreed on by the Paris conference10 are on the left. (The major chromosome section numbers are indicated but the sub-numbers for individual bands have been deleted because of the low magnification here.)
The 5S genes are placed near q41 or q42 on chromosome 1, which correspond to the first proximal band and interband in 1 q4 indicated by the arrow. The 'noise level' radioactivity on chromosome 2 is randomly distributed. A minor 5S gene site may be on chromosome 3 but the data are inconclusive.

In almost every cell examined, chromosome 1 was labelled at a site near the end of the long arm (q) with an average of 2.8 silver grains per locus. In Fig. 1 the chromosomes in the A group from six cells are compared with the standardised chromosomes agreed at the Paris chromosome conference<sup>10</sup>. Measurements of chromosome 1 that exhibit clear banding at 1q12 place the 5S genes on the long arm at about 1q41. The location of this 5S gene site has been confirmed using 125I-5S RNA to label the chromosomes from two fibroblast cultures, which were heterozygous for different translocations<sup>11</sup>. With one aberration, t(1;13) (q32;q34), the 5S locus on chromosome 1 was translocated to chromosome 13. In the second aberration, t(1;4) (q44;q25), the 5S genes were not translocated to chromosome 4. The data are all consistent in placing the major 5S RNA locus on the long arm of chromosome 1 at or near q41 and within the segment q32 to q44 as bracketed by translocation breakpoints.

The localisation of 5S genes on the remaining chromosomes of the genome is less straightforward. An identified chromosome must be labelled consistently at a particular site, otherwise the data are meaningless. It has not been possible to identify labelled chromosomes with certainty because of variable banding patterns. The information that follows is an attempt to provide tentative assignments for the 5S genes, and provides a qualitative analysis of each chromosome group (A-G) shown in Fig. 2, obtained from the karyotypes of 34 cells at metaphase (20 male and 14 female). (A) Chromosome 1 is the most heavily labelled. Chromosome 2 is not labelled above background, however, 3 may be labelled but at a frequency of silver grains too low to place a site. (B) Chromosomes 4 and 5 are not labelled above noise level binding. (C) One or two pairs of the middle sized chromosomes are labelled. In cells showing distinct C banding, chromosome 9 is usually labelled.

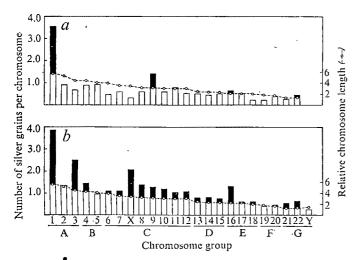

Fig. 2 An analysis of autoradiographs from metaphase chromosomes hybridised with <sup>123</sup>I-5S RNA. Radioactivity and relative chromosome length are plotted according to chromosome number. Chromosomes 1, 2, 3 and 16 are identified with reasonable certainty. The placement of the remaining chromosomes is reliable only within a group according to their measured length. This latter placement is analogous to the older criteria before G and C banding techniques were available. The assignment of the chromosomes in the top set (female 40°C) is more accurate because some chromosomes had prominent C bands, which apply especially to assignments within the C group. a, These chromosomes are from cultured leukocytes of an adult female. The hybridisation with 1 µg <sup>123</sup>I-5S RNA per mt was done at 40°C in 50% formamide in 2×SSC overnight. b, These chromosomes are from cultured leukocytes of an adult male. The hybridisation conditions are the same, except that the slides were incubated at 60°C for one hour before transfer to the optimum temperature at 40°C overnight. A 60°C temperature in 50% formamide will melt the SS DNA. We believe that some non-histone proteins are removed with these conditions because of increased hybridisation efficiency.

When the X chromosome can be identified by banding, it is not labelled. (D) Chromosomes 13, 14 and 15 do not seem to carry 5S genes nor do detected levels of annealing occur at the satellited regions that would indicate contamination from 18S or 28S ribosomal RNA. (E) Chromosome 16 probably has 5S genes. The identification of 16 is reliable because the centromere is located centrally and there is a large C band at q11. Chromosome 17 and 18 are not labelled above background. (F) Neither 19 nor 20 are labelled. (G) Chromosome 22 might have 5S genes but 21 and the Y probably do not, and the Y exhibits less 5S RNA binding per unit length than any other chromosome. Thus besides the definite localisation on 1, tentative assignments indicate that chromosomes 9 and 16 probably have 5S genes. Chromosomes 3 and 22 have above average labelling but remain in question. The overall distribution of the 5S genes is consistent with previous hybridisation studies7.

In interphase nuclei the 5S RNA genes have been observed to cluster around nucleoli in Drosophila12.13, Xenopus3 and the Chinese hamster<sup>14</sup>. (We have verified these results in the Chinese hamster, where the 5S RNA genes are clustered around nucleoli.) With interphase nuclei from mouse Sertoli cells, human leukocytes and human fibroblasts the radioactivity from annealed 5S RNA is associated with nucleoli16. An analysis of interphase nuclei from 100 human fibroblasts shows that 50-70% of the 125I-5S RNA radioactivity is associated with nucleoli. A random distribution would be 20-30%. Centres of radioactivity and lines of 6-10 silver grains are usually over nucleoli and at the edge11. Many of these highly labelled sites should be the 5S genes on chromosome 1. Most nuclei with 3 or 4 nucleoli have label associated with each nucleolus, indicating that more 5S genes are present than on chromosome 1.

The obvious advantage of this nucleolar association would be to synthesise 5S RNA in proximity of nascent particles for effective assembly of 5S RNA into the 60S ribosomal particles. Interphase nuclei seem to possess a mechanism to position certain chromosome segments into a consistent three-dimensional configuration. What is the physical basis for the association of the ribosomal precursor genes?

Certain information about human chromosomes—(a) banding patterns10; (b) the location of C bands and the highly repeated DNA sequence16; (c) the localisation of the ribosomal RNA gene at the secondary constrictions of the D and G group chromosomes 13, 14, 15, 21 and  $22^1$ , and (d) the 5S gene sites described here—shows that the chromosomes with large blocks of highly repeated DNA (C bands) are either nucleolus organiser chromosomes (13, 14, 15, 21 or 22) or chromosomes 1, 9 and 16, reported here to have 5S genes. C-RNA from satellite II anneals to the C band on chromosome 1 at q12 and with the C band on chromosome 16 at q1117. After long exposure, these same in situ preparations gave labelling at the C band on chromosome 9 at q12 and at the nucleolar heterochromatin. Are these highly repeated DNA sequences the recognition sites which position the ribosomal precursor genes?

Ferguson-Smith and Handmaker<sup>18</sup> analysed the position of the nucleolus organiser (NO) chromosomes in relation to the location of other chromosomes in 432 mitotic cells. Chromosome 1 was consistently associated with the NO chromosomes, and direct attachments were illustrated between the C band q12 on chromosome 1 and the nucleolar heterochromatin end of a chromosome in the D or G group (Plate 3A-C of ref. 18). Shaw made a similar observation<sup>19</sup> where the D and G group chromosomes were adjacent to chromosome 1, usually at right angles to the acentric ends of the D or G chromosomes that point toward the centromere of chromosome 1. The evidence suggests that the highly repeated DNA sequences function to orient and position the genes which synthesise the RNA for ribosomes.

Even though the assignments of 5S genes to chromosomes 9 and 16 will require further cytogenetic verification before

their mapping can be accepted, some observations on association should be noted. Using high pH Giemsa staining the large heterochromatic block on chromosome 9 could be recognised at interphase in fibroblasts and Sertoli cells20. This block was often associated with the small nucleoli of fibroblasts and showed a frequency of 84% attachment of Sertoli cell nucleoli. In seven consecutive patients with chronic myelogenous leukaemia, Rowley<sup>21</sup> found that a piece of chromosome 22, an NO chromosome, was translocated to chromosome 9. These two chromosomes must have been closely associated at interphase to produce the translocation.

We thank Dr T. Borun for HeLa 5S ribosomal RNA. This research was supported by grants from the United States National Science Foundation (to D.M.S.) and the University of Illinois Graduate Research Board. We thank Paul Szabo and Mrs L. Cooper for their help.

# Pseudotype formation between enveloped RNA and DNA viruses

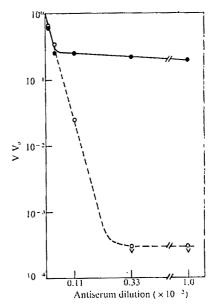

ENVELOPED RNA viruses from different groups participate readily with each other in phenotypic mixing during maturation at the plasma membrane of host cells. These 'pseudotypes' with the envelope antigens of one virus and the genome of the other have been demonstrated for simian virus 5 and vesicular

stomatitis virus (VSV)1, for avian or murine RNA tumour viruses and VSV<sup>2-4</sup>, and for fowl plague virus and VSV<sup>5</sup>. (An exception has been the lack of interaction between Sindbis virus and VSV6.) We have now found virions containing the RNA genomes of VSV in the envelope antigens of a DNA virus, herpes simplex virus (HSV). These interactions between genomes and antigens of unrelated groups may be part of a mechanism for viral pathogenesis and oncogenesis.

Coinfection of cells with HSV and VSV would be expected to result in progeny containing either the HSV or VSV genomes. To differentiate between plaques, the morphology and efficiency of plaque formation by VSV and HSV were examined. HSV was assayed on both human epidermoid number 2 (HEp-2) cells and on Chinese hamster ovary (CHO) cells under liquid or agar overlays, and VSV was assayed on both cell types under agar only. The results of many experiments are summarised here.

The MP strain of HSV7 formed no detectable plaques on CHO cells. (We show below that this restriction was due to the inability of HSV to enter CHO cells.) The Indiana serotype of VSV8, on the other hand, grew well on both types of cell, although the efficiency of plaque formation on HEp-2 cells was only 10% of that on CHO cells.

The MP strain of HSV forms polykaryocytes on HEp-2 cells when the cells are incubated under liquid overlay containing anti-HSV antiserum7. Under agar, HSV on HEp-2 cells appeared as very small, red plaques and small, clear white plaques. HSV plaques were similar whether the agar overlay contained anti-HSV antiserum or not. The white plaques, although similar in size to VSV plaques on HEp-2 cells, were distinguishable by their appearance under the microscope.

Neutralisation by anti-VSV serum of VSV(HSV) pseudotypes formed after mixed infection in the presence of cytosine arabinoside. HEp-2 cells were infected with HSV at a multiplicity of 2 in the presence of 20 µg ml<sup>-1</sup> of cytosine arabinoside and incubated at 37° C for 4.5 h. Then the cells were superinfected with VSV at a multiplicity of 0.01. After each attachment period the cells were washed twice with 10 ml of saline. The cells were covered with MEM containing 2% FCS, 5 µg ml<sup>-1</sup> gentamicin and 20 µg ml<sup>-1</sup> cytosine arabinoside. After a total incubation time of 30 h at 37° C, the extracellular fluid was decanted, cells and cell debris precipitated and the supernatant frozen at -100° C. For neutralisation mixtures the supernatant containing VSV and VSV(HSV) progeny was thawed and mixed with equal volumes of rabbit anti-VSV antiserum<sup>3</sup> at the indicated dilutions. Neutfalisation was for 1 h at 22° C and then the samples were diluted and plaque assayed on either HEp-2 or CHO cells as indicated for Table 1. The log of the percentage of non-neutralised virus  $V/V_0$  is plotted against the antibody concentration.  $\bullet$ , Hep-2;  $\bigcirc$ , CHO.

A sample of 4.5 × 10<sup>6</sup> human epidermoid number 2 (HEp-2) cells<sup>17</sup> were infected with the MP strain of herpes simplex virus type I (HSV-1)<sup>7</sup> at a multiplicity of 1 and superinfected 4 h later with vesicular stomatitis virus (VSV) of the Indiana serotype at a multiplicity of 0.4. The infected cells were incubated in Eagle's minimal essential medium (MEM) containing 10% foetal calf serum (FCS) and 5 μg ml<sup>-1</sup> of gentamicin. After 24 h extracellular virus was collected as previously described<sup>18</sup>. A similar sample of HEp-2 cells was mock-infected with HSV then infected with VSV at a multiplicity of 0.4 and collected at the same time as the previous sample. Neutralisation mixtures were made by first diluting antiserum against VSV 1:50 and antiserum against HSV 1:100. Each serum was mixed in equal volumes with each of the two virus preparations which had been diluted previously to yield approximately 10<sup>3</sup>–10<sup>4</sup> PFU ml<sup>-1</sup> on the respective cells. Where both antisera were used against one of the virus preparations, both concentrations of antisera were each identical to the concentration of antiserum when used alone. Neutralisation mixtures were allowed to stand at 22° C for 1 h and then diluted. Unneutralised virus preparations were treated identically except that antisera were absent. Virus in duplicate aliquots of 0.1 or 0.2 ml of the appropriate dilutions were attached to monolayer HEp-2 or Chinese hamster ovary (CHO) cells on 60 mm plastic Petri plates for 40 min at 37° C. The cells were then rinsed with medium and overlaid with MEM containing 2% FCS, 5 μg ml<sup>-1</sup> of gentamicin and 0.9% agar. After incubation at 37° C for 48 h in a 5% CO<sub>2</sub> humidified incubator, the cells were stained with 0.01% neutral red and the plaques counted after another 18 h of incubation.

\* Rabbit anti-VSV antiserum was prepared as described previously<sup>3</sup>. † Anti-HSV serum was human immune serum globulin provided by Dr Michael Oxman and prepared by the Department of Public Health of the Commonwealth of Massachusetts.

‡ HEp-2 cells and their properties have been described before<sup>19</sup>. § CHO cells and their properties have been described<sup>18, 20</sup>.

The efficiency of plaque formation of HSV with a liquid or agar overlay was approximately the same.

When HEp-2 cells were infected with HSV and later superinfected with VSV, results were different depending on the multiplicity of VSV. At high multiplicities (>1) only progeny VSV were detectable in the extracellular medium. These progeny were neutralised by anti-VSV serum whether they were assayed on HEp-2 or CHO cells.

During mixed infection with smaller multiplicities of superinfecting VSV (<1) both VSV and HSV progeny were detected in the extracellular medium. Table 1 shows the results when VSV plaques were recorded. On HEp-2 cells one-third of the VSV progeny produced by the mixed infection was resistant to neutralisation by anti-VSV serum. This resistant VSV population did not form plaques on CHO cells and was neutralisable by anti-HSV serum when assayed in HEp-2 cells. A control sample of progeny from HEp-2 cells infected with only VSV is presented for comparison. Anti-HSV antiserum had no effect on this VSV preparation. These results demonstrate the presence of virions containing VSV genomes covered by HSV envelope antigens which are designated pseudotypes of VSV(HSV).

To ensure that there was no confusion between the VSV and HSV plaques in this experiment, we took advantage of reports that cytosine arabinoside inhibits HSV DNA synthesis without marked inhibition of the synthesis of plasma membrane-associated HSV glycoproteins<sup>9,10</sup>. Because our experiments

were designed to assay only released extracellular virions, the growth of HSV for 28 h under these conditions was determined in the presence of 1–50  $\mu g$  ml $^{-1}$  cytosine arabinoside. The growth of detectable extracellular HSV progeny was inhibited by more than 99.9% at these concentrations of cytosine arabinoside (data not shown). Less than 10° PFU per ml was detected. The same inhibitor at 20  $\mu g$  ml $^{-1}$  had no effects on the synthesis of VSV in HEp-2 cells, nor did it result in marked cytotoxicity of uninfected HEp-2 cells after a 30 h treatment at 37° C.

HEp-2 cells coinfected with HSV and VSV in the presence of cytosine arabinoside should synthesise HSV glycoproteins, but the progeny should contain only those with VSV genomes. To detect VSV(HSV) pseudotypes three different protocols were used for these mixed infections. In each case HEp-2 cells were infected with HSV at a multiplicity of 2 in the presence of 20 μg ml<sup>-1</sup> cytosine arabinoside. These cells were superinfected with VSV at a multiplicity of 0.01, 4.5 and 6.5 h after HSV infection. A third sample was superinfected, 22 h after HSV infection, with VSV at a multiplicity of 50. All three samples were collected 30 h after HSV infection, when the cytopathic effect of VSV was evident.

Of the infectious progeny from these mixed infections 3-20% were resistant to neutralisation by anti-VSV serum. A more detailed characterisation of the sample superinfected with VSV at 4.5 h is shown in Fig. 1 and Table 2. A persistent fraction of 20% was detected on HEp-2 cells after neutralisation with anti-VSV serum (Fig. 1). This persistent fraction was not detected on CHO cells (Fig. 1). Such findings indicate a surface restriction<sup>2,3</sup> for VSV(HSV) on CHO cells and may explain the lack of susceptibility of some Chinese hamster cells to HSV<sup>11,12</sup>.

A control preparation of VSV made in HEp-2 cells in the presence of 20 µg ml<sup>-1</sup> cytosine arabinoside was neutralised by anti-VSV serum (Table 2). In addition, VSV(HSV) from the mixed infection was neutralised specifically by anti-HSV serum (Table 2).

These results confirm the findings that specific alteration of host plasma membranes by HSV occurs although HSV progeny do not use plasma membranes during their maturation<sup>13-15</sup>. Presumably, during budding VSV genomes pick up HSV-specific antigens. Also, VSV(HSV) pseudotypes indicate that enveloped DNA and RNA viruses mix phenotypically. The process appears to be quite efficient because 30% of the VSV population can be pseudotypes. It remains to be shown whether this percentage will be as high when strains other than the macroplaque (MP) strain of HSV are used in mixed infections.

If pseudotype formation occurs between VSV and other herpes-like viruses, the rescue of membrane markers by VSV from human tumour cells<sup>16</sup> might be the result of partial gene

Table 2 Neutralisation of pseudotypes by human immune globulin

Virus	Anti-VSV	Anti-HSV	PFU ml <sup>-1</sup> ×10 <sup>-3</sup>
VSV-CA*	-		1.250
VSV-CA	+		< 0.001
VSV(HSV)†	- Parkers		9.820
VSV(HSV)	+		0.475
VSV(HSV)	_	+	8.620
VSV(HSV)	+	+	< 0.001

Neutralisation mixtures were made with equal volumes of virus and anti-VSV and/or anti-HSV sera. Details of neutralisation and plaque assay on HEp-2 cells were identical to those described for Table 1.

\*VSV-CA was prepared in  $5 \times 10^6$  HEp-2 cells by first treating the cells with cytosine arabinoside at 20 µg ml<sup>-1</sup> in MEM for 6 h at 37° C and then infecting with VSV at a multiplicity of 0.1. The inhibitor was maintained in the medium. After incubation for 19 h at 37° C VSV was collected from the extracellular fluids.

†This preparation of virus was identical to the preparation shown in Fig. 1. Compared with Fig. 1, the reduction in titre of the percentage of PFU resistant to neutralisation by anti-VSV serum probably due to the disruption of HSV envelopes resulting from repeated freezing and thawing of the same virus preparation.

expression of herpes-like viruses as well as RNA tumour viruses. Also, although it is premature to conclude anything about the effect of pseudotype formation on viral oncogenesis, possible interactions of herpesviruses with RNA viruses at the level of host membranes may result in the rescue of defective herpesviruses by other enveloped viruses, and in the rescue of defective RNA tumour viruses by herpesvirus-coded surface

# Effect of dexamethasone on herpes simplex virus type 2 infection in vitro

MORRHENN et al.1 reported that when polyoma virus-infected cultures of mouse embryo fibroblasts and 3T3 cells were treated with physiological doses of corticosteroids, plaque formation was enhanced tenfold. Because the plaques appeared earlier and were larger in the presence of steroids, they suggested that the rate of production of virus was also increased. It has also been reported that glucocorticoids influence in vitro infections with murine leukaemia virus and mouse mammary tumour virus<sup>2,3</sup>. Since there is epidemiological evidence that herpes simplex type 2 (HSV-2) can be oncogenic in man4 and evidence that inactivated HSV can produce malignant transformation in vitro<sup>5</sup>, we studied the effect of corticosteroids on HSV-2 infection in mouse embryo fibroblasts and 3T3 cells, the two cell

types in which effects had been noted with polyoma virus. We report here that dexamethasone has different effects on HSV-2 infection in vitro depending on both the type of cell tested and the characteristics of the viral strain used.

The MS strain of HSV-2 was obtained from Dr L. W. Catalano and grown in our laboratory in Vero cell cultures in RPMI 1640 medium with 5% feotal bovine serum. Two substrains, one highly syncytia-forming (HSV-2syn) and the other predominantly non-syncytia-forming (HSV-2non-syn), were obtained by plaque purification from the uncloned virus which produced both syncytial and non-syncytial plaques on Vero

Virus pools were grown in Vero cells and titrated by plaque assay with a methylcellulose overlay as before8. 3T3 cells were obtained from Dr George Todaro and Swiss mouse embryo fibroblasts (SMF) were obtained from Microbiological Associates. All experiments were performed with monolayer cultures in 25-cm<sup>2</sup> Flacon plastic flasks.

Dexamethasone (10<sup>-5</sup>–10<sup>-7</sup> M) and cortisol (10<sup>-6</sup> M Sigma) were prepared in absolute ethanol and dissolved to appropriate concentrations in medium or in the methylcellulose overlay. Media for control cultures contained ethanol in amounts equal. to those in the steroid-containing media.

Monolayers of 3T3 cells were preincubated for 24h in glucocorticoid-containing medium, infected with HSV-2 syn and fed with medium containing glucocorticoid, and the total amount of virus produced 24 h after infection was measured by plaque assay in Vero cell cultures6. A tenfold or greater increase in yield of virus was found in several experiments (Table 1).

Table 1 Effect of glucocorticoids on production and plaquing efficiency of HSV-2syn on 3T3 cells

		Viral yield	
Glucocorticoid			No. of plaques*
		(PFU per flask)	
Dexamethasone	10⁻⁵ M	$1.8 \times 10^{\circ}$	82
	10 −6 M	$4 \times 10^{7}$	75
	10 -7 M	$3 \times 10^7$	60
Cortisol	10 <sup>−6</sup> M	$1 \times 10^7$	83
Control		5×10 <sup>5</sup>	16

Flasks containing 3×106 cells were infected with 108 PFU of HSV-2syn. The 24 h viral yield was measured after two cycles of freezing and thawing of cells and supernatant, followed by centrifugation at 1,000 r.p.m. for 10 min to remove cell debris, and then by plaque assay on Vero monolayers

Input 200 PFU as measured on Vero monolayers. Figures are averages of those for two replicate flasks.

To test whether the 3T3 monolayers had become more susceptible to HSV-2syn infection under the influence of the steroids, we studied the plaquing efficiency of the virus with a methylcellulose overlay containing steroids. Repeated experiments showed a twofold to fivefold increase in the number of plaques in the cultures treated with 10<sup>-5</sup>–10<sup>-7</sup> M dexamethasone and 10<sup>-8</sup> cortisol compared with ethanol controls (Table 1).

Because Thrash and Cunningham<sup>7</sup> have shown that dexamethasone stimulates DNA synthesis and division of contactinhibited 3T3 cells we measured the 24 h viral production of HSV-2syn in growing, non-confluent monolayers compared with contact-inhibited 3T3 confluent cell cultures. We found no significant differences in the yields. Thus the increase in viral production seems to be independent of the stimulation of division of contact-inhibited 3T3 cells by glucocorticoids.

In contrast to the results with HSV-2syn and 3T3 cells, when SMF monolayers were infected with HSV-2syn, steroids produced no change in 24 h viral production or plaquing efficiency. Dexamethasone and cortisol did, however, cause a decrease in the size of the plaques (Table 2). The reduction in plaque diameter correlated with a decrease in the ratio of released virus to cell-associated virus 24 h after infection (Table 3).

Since the spread of virus and plaque formation with HSV-

Table 2 Reduction in size of HSV-2syn plaques in SMF with glucocorticoid

			_
Glucocorticoid		Plaque size (mm)	
Dexamethasone	10-5 M	1.05	
Donaine in an a	10 <sup>-6</sup> M	1.15	
	10 <sup>-7</sup> M	1.4	
Control		2.4	
Control			

Plaque diameter figures are averages of measurements of 10 plaques. The plaques were measured by a linear grid inserted in the ocular piece of a dissecting microscope.

2syn are related to both formation of polykaryocytes and release of virus from infected cells we investigated the effects of steroids on infection of SMF by non-syncytial HSV-2. We found no effects on virus yield, released fraction of virus, plaquing efficiency or plaque size. The reasons for this difference between the strains of HSV-2 are not clear, although steroids apparently affect the release of virus from polykaryocytes produced by HSV-2syn in SMF cultures but not from the mononuclear cells releasing HSV-2non-syn.

Table 3 Influence of glucocorticoids on the released fraction of HSV-2syn infecting SMF

Glucocorticoid		Viral yield (PFU		R/CA ratio
		Cell-associated (CA)	Released (R)	
Dexamethasone	10 <sup>-5</sup> M	28.8×10 <sup>5</sup>	$80 \times 10^{5}$	2.7
	10-6 M	28×105	$70 \times 10^{5}$	2.5
	10 <sup>-7</sup> M	36×105	15×105	0.4
Cortisol	10 <sup>-6</sup> M	$18 \times 10^{5}$	$45 \times 10^{5}$	2.5
Control	28 100	5 × 10 <sup>5</sup>	140×105	28.0

<sup>\*</sup> Input 1×105 PFU per flask. Twenty-four hours after infection the supernatant of the cultures was collected and the virus present was titrated as 'released virus'. After removing the supernatant, 2 ml of medium was added to the culture flasks and the intercellular virus was recovered as described in the total viral yield experiments.

Our results show that the effect of glucocorticoids on HSV-2 infection in vitro depend on the type of cell culture as well as the characteristics of the viral strain. In 3T3 cells infected with the syncytial strain of HSV-2, steroids produce increased yields of virus and twofold to fivefold increases in plaquing efficiency. In Swiss mouse fibroblasts, steroids produce no increase in virus yield or plaquing efficiency, but there is a decrease in plaque size and amount of virus released from cells infected with the syncytial strain. The findings suggest that in HSV infections in vivo, in addition to effects on the immune system, steroids act directly on infected cells to either increase susceptibility and yield, or decrease release.

# Increased susceptibility to virus oncogenesis of congenitally thymus-deprived nude mice

A ROLE of thymus-deprived (T) lymphocytes in controlling tumour development has been widely discussed. The most convincing evidence in support of such a mechanism comes from observations on the induction of tumours by polyoma virus in adult mice1. Normal adult mice do not develop tumours after infection with the virus, but mice deprived of T lymphocytes by thymectomy and repeated inoculations of anti-lymphocytic serum and infected with polyoma virus as adults do develop tumours. If such animals are reconstituted with T lymphocytes from syngeneic immune donors, tumours do not develop.

Congenitally thymus-deprived (nu/nu) mice provide a convenient test system for analysing the role of T lymphocytes in surveillance against tumours. These mice are unusually susceptible to infections by certain viruses and other agents1, and they soon die if maintained in normal laboratory colony conditions. Nude mice can be maintained under special conditions for longer and those surviving for 7 months have not developed tumours spontaneously2. The time of appearance and numbers of tumours in nude mice treated with methylcholanthrene were not significantly different from those in control mice3; the relatively large dose of carcinogen used could have been immunosuppressive, however, and the skin of a nu/nu mouse is clearly abnormal.

These observations have raised some doubts about the role of T lymphocytes in surveillance against tumours. We decided, therefore, to investigate the susceptibility of nu/nu mice to tumour induction by viruses. The nu/nu mice used were bred in this institute on a TO background; 20 male nu/nu mice and 20 littermate control nu/+ mice aged 6-8 weeks were infected with polyoma virus. One half of the nu/nu and control animals were

Nude mouse 8 weeks after infection with polyoma virus, showing multiple skin tumours.

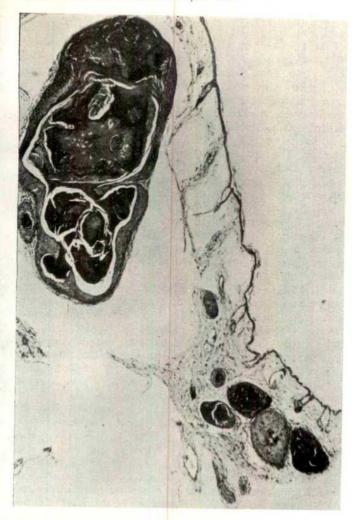

Fig. 2 Section of nude mouse skin, showing one large and several small tumours. (× 550).

injected intraperitoneally with 0.2 ml horse anti-mouse lympho cyte serum (ALS) twice weekly for 8 weeks. No tumours developed in any nu/+ mice. All nu/nu mice given ALS developed skin tumours within 4 weeks. Beginning 4 weeks after infection, untreated nu/nu mice developed skin tumours, and by 12 weeks all had multiple skin tumours (Fig. 1). The tumours were mostly carcinomas of the hair follicles (Fig. 2) and occasionally of sebaceous glands. Some mice also showed widely disseminated bone tumours, involving the femur, tibia, pelvic bones, vertebrae and ribs, as detected by radiological examination. The histological appearance was that of endosteal and periosteal osteosarcoma, the latter infiltrating muscle. Each animal had several bone tumours, mostly small but some as large as I cm in diameter. Other tumours present in the animals included adenocarcinomas of the salivary glands, carcinomas of the renal cortex and flat transitional-cell carcinomas of the renal pelvis.

In another experiment 6 male nu/nu mice and 12 nu/+ littermate control mice aged 8 weeks were inoculated intra-

Table 1 Tumours induced in nu/nu mice inoculated with polyoma virus at 6-8 weeks of age

Skin hair follicular carcinoma Osteosarcoma	% Tumours 100.0

Carcinoma of kidney	45.6 55.6
Transitional cell carcinoma of rena	pelvis 27.3

106 plaque-forming units of the small-plaque variant of SE polyoma virus inoculated intraperitoneally.

muscularly with 103 ID50 of murine sarcoma virus (MSV/M). None of the heterozygous control animals developed tumours, whereas all nu/nu mice developed large tumours of their thighs and were killed 3 weeks later. They also had marked splenomegaly and histological examination showed lesions in the muscle and thighs expected of murine sarcoma virus\*.

These results show that nu/nu mice are highly sensitive to virus oncogenesis at an age when their heterozygous littermates are resistant, confirming the major role of T lymphocytes in limiting virus oncogenesis. The accelerated development of tumours in recipients of ALS, however, suggests that there may be a second surveillance mechanism which does not involve T lymphocytes, possibly the antibody-dependent effector cell system5. This might account for the low incidence of tumours recorded in nu/nu mice2, although they were observed only for 7 months.

MSV/M was provided by Dr J. J. Harvey.

Note added in proof: Prof. M. Vandeputte, Leuven, Belguim, has independently found that nude mice are highly susceptible to oncogenesis when infected with polyoma virus as adults.

## Effect of hypophysectomy on a virus-induced T-cell leukaemia

We have found that removal of the pituitary from rats decreases their susceptibility to leukaemia induced by Gross virus. This provides preliminary support for our hypothesis that the pituitary through one of its hormones, is involved in leukaemogenesis.

Gross passage A virus was injected intraperitoneally into newborn Sprague-Dawley rats. At 3 weeks of age the animals were weaned and separated by sex, and approximately half of them were hypophysectomised. At weekly intervals thereafter they were weighed and then a differential and total white blood cell count was performed. Autopsies were conducted after death and leukaemia was diagnosed on the basis of gross and microscopic findings of the presence of typical lymphoblasts in the peripheral blood. Autopsied animals had thymus tumours and other pathology typical of T-cell leukaemia1. Hypophysectomy was considered to have been complete if the animals gained less than 100% of their weight after surgery and the pituitary was absent at autopsy.

By 12 weeks after injection of the virus, the incidence of leukaemia was none out of 11 in hypophysectomised rats, 8 out of 12 in incompletely hypophysectomised rats, and 37 out of 37 in unoperated rats.

Thus hypophysectomy significantly impairs leukaemogenesis induced by Gress virus. It is not clear at the moment why our results conflict with those of Nagareda and Kaplan who found that hypophysectomy did not impair radiation-induced leukaemia in C57BL mice2. In their study the T-cell lymphomas appeared slightly earlier in the operated animals.

The possibility that at least one phase of leukaemogenesis depends on the pituitary suggests new ways of investigating leukaemia in both experimental animals and man. In the case of

a T-cell lymphoma the pituitary may be affecting the thymic epithelium to create the conditions appropriate for leukaemogenesis. It may do this through known hormones, such as growth hormone or prolactin, or unknown hormones such as a thymus-stimulating hormone. Growth hormone which influences thymus development, may be the critical hormone<sup>3</sup>. If so, it probably acts by stimulating the synthesis of somatomedin, perhaps even a somatomedin unique for the thymus. If Gross virus impairs the synthesis of this somatomedin, leukaemia may develop as a consequence of the lack of a feedback inhibitor to suppress pituitary stimulation of the thymus.

# In vitro sensitisation to dinitrochlorobenzene in guinea pigs

According to Medawar's concept of peripheral sensitisation<sup>1, 2</sup> the induction phase of contact sensitivity may consist of a sequence of three stages. These are the formation of antigen by conjugation of the hapten with skin proteins; the recognition of this antigen by circulating lymphocytes and the activation of these cells passing by the site of antigen application; and the proliferation and differentiation of these activated lymphocytes in the draining lymph node resulting in development of memory and affector cells.

guinea pigs highly purified from granulocytes and macrophages on a glass bead column were incubated in a  $10^{-6}$  M solution of dinitrochlorobenzene (DNCB) in medium 199 containing 10% isologous guinea-pig serum for 3 h at  $37^{\circ}$  C in a 10% CO<sub>2</sub> atmosphere. Suspension of  $5\times10^{6}$  cells per ml medium were used. After removing as much free DNCB as possible by at least four washings,  $3\times10^{7}$ – $5\times10^{7}$  lymphocytes in 0.2 ml medium were injected intradermally into the skin of the left ear of strain-13 recipients. These animals were skin-tested 14 d later with 0.09%, 0.05% and 0.03% DNCB solutions in acetone. The contact reactions were read 24 h later and assessed according to an arbitrary scale from 0 to 3 (ref. 4). The degree of hypersensitivity was expressed as the total of all three readings in each animal.

In the first group donors and recipients were normal strain-13 guinea pigs. In the second group the possible active sensitisation of the recipients by the hapten conjugated to lymphoid cells was excluded by using tolerant guinea pigs as recipients. Tolerance to DNCB was induced by two intravenous injections of dinitrobenzenesulphonic acid sodium salt (DNBSO<sub>3</sub>) 28 d and 14 d before the transfer. It has been shown that tolerance induced by this method is complete and permanent and cannot be broken even by using dinitrofluorobenzene (DNFB) in FCA for sensitisation (group 5). In the third group, allogeneic peritoneal exudate lymphocytes from Himalayan spotted white guinea pigs were used as donor cells assuming that rejection of these cells will prevent the adoptive sensitisation of recipients having no effect on a possible active sensitisation with hapten-lymphocyte conjugate. In the fourth group, lymphocytes from tolerant donors incubated with the hapten were transferred to normal syngeneic recipients.

The results are summarised in Table 1. It is evident that peritoneal exudate lymphocytes treated *in vitro* with a nontoxic solution of DNCB are capable, when transferred to normal syngeneic recipients, of inducing contact sensitivity to this hapten, as demonstrated by a positive epicutaneous test 14 d after the transfer. This effect could be the result of either sensitisation of the lymphocytes *in vitro* or the formation of a strongly immunogenic antigen by conjugation of DNCB with lymphocytes, as shown by Baumgarten and Geczy<sup>5</sup>, Asherson

Table 1 Sensitisation of guinea pigs by intradermal injection of in vitro DNCB-treated lymphocytes

<sup>\*</sup> Tolerant guinea pigs not receiving cells but injected with 500 µg DNFB in FCA and tested 14 d later.

Macher and Sommer<sup>3</sup> failed to demonstrate convincingly peripheral sensitisation of lymphocytes in their combined in vitro-in vivo model using outbred guinea pigs, but their results do not exclude this concept either. Their main difficulty was to distinguish between active sensitisation with hapten-conjugated lymphocytes and transfer of sensitivity with cells already sensitised in vitro.

Here in our study, a similar model was used to solve this important problem. As tolerant guinea pigs cannot become sensitised by application of the hapten but are adoptively sensitised by cells from hypersensitive donors, immunocompetent lymphocytes, when activated in vitro, should also induce contact sensitivity in tolerant recipients.

Peritoneal exudate lymphocytes from inbred strain-13

et al.6 and McFarlin and Balfour?. This second possibility was excluded, however, in the experiments in groups 2 and 3.

It was demonstrated that guinea pigs rendered tolerant by two intravenous injections of DNBSO<sub>3</sub> cannot become actively sensitised even when a relatively high dose of hapten (500 µg DNFB) in FCA is used for sensitisation (group 5) and epicutaneous tests were repeated for a period of more than 1 yr. The tolerant animals become hypersensitive, however, by adoptive transfer of lymphoid cells from hypersensitive donors<sup>8</sup>.

It was shown recently that tolerance in contact sensitivity may be caused by specific suppressor cells preventing the proliferation of normal immunocompetent lymphocytes, probably at a very early stage. Our results in group 2, showing that 12 out of 16 tolerant recipients of lymphocytes preincubated with DNCB in vitro became sensitised, indicate that these cells already reached a stage when they cannot be inhibited by the suppressor cells any more. These results favour the concept of in vitro sensitisation or at least activation of specific immunocompetent lymphocytes. The higher degree of sensitivity of normal recipients in comparison to tolerant ones might be caused by additional active sensitisation of normal animals, but not of tolerant ones, with a conjugate of DNCB with lymphoid cells<sup>5-7</sup>.

The idea that lymphocytes can actually be sensitised in vitro is further supported by the finding that allogeneic cells (group 3) as well as non-viable autologous cells3 have no sensitising capacity, although their capacity to form immunogenic conjugates may not be altered.

The results in group 4 do not necessarily contradict the hypothesis of peripheral sensitisation; they need, however, a further explanation. One possibility is that the lymphocyte suspension from tolerant donors may either not contain suppressor cells or these cells are not able to act in vitro and prevent immunocompetent cells from becoming activated by preincubation with the hapten.

As it is known that guinea pigs can become sensitised to DNCB conjugated to different homologous skin and serum proteins10, and therefore also to DNP-conjugates formed with proteins of the culture medium, the present results might be regarded as evidence that the first two steps of the induction phase of contact sensitivity, namely formation of the antigen and its recognition by immunocompetent cells, can be accomplished also in vitro. Lymphocytes incubated with DNCB in vitro become activated beyond a stage where they cannot be inhibited any more by suppressor cells. An intradermal injection of these cells acts somehow as an adoptive sensitisation. An additional active sensitising effect of a DNCB-lymphocyte conjugate, however, may not be excluded when normal recipients are used. This may explain the higher degree of sensitisation in normal recipients than in tolerant ones.

As the sensitisation of tolerant recipients can be achieved only by transfer of already specifically activated lymphocytes, we assume that in our experiments cells incubated with the hapten in vitro were actually sensitised. The fact that in our in vitro-in vivo model the initial steps of sensitisation are accomplished in vitro may be regarded as support for the concept of peripheral sensitisation.

# Large numbers of cells in normal mice produce antibody components of isologous erythrocytes

THERE are a number of arguments against the idea' that self-tolerance depends on a purge of all self-reactive ciones early in development. First, antigens which appear later in development, for example, Ig idiotypes, must induce tolerance to themselves. Second, autoimmune diseases are often reversible, implying that when anti-self-reactive cells arise late, they may still be controlled. Third, the recent finding (refs 2-4 and L. M. Pilarski and A.J.C., unpublished) that single clones of antibody-forming cells rapidly produce variants also implies a continuous monitoring and control of immunocompetent cells. Self-reactive variants must arise during many immune responses, and must normally be prevented from causing autoimmune disease. Fourth, the distinction between anti-self and anti-not-self specificities is obviously not clear-cut. Given the great diversity of self components in mammals, it is probable that almost any antibody will react to some self antigens with low affinity.

These considerations suggest that normal animals may contain many auto-reactive cells which are, however, prevented from causing autoimmune disease by some control mechanism. Here I demonstrate plaque forming cells (PFCs) against components of autologous erythrocytes (RBCs) in normal mice.

Although others have reported the presence of small numbers of plaques on normal isologous RBCs\*-7, I could not find such PFCs in spleens of 8-week-old CBA mice. When their RBCs were first treated with any of the proteolytic enzymes trypsin, papain or bromelain, however, several thousand PFCs were found per spleen in normal mice of this and other strains (Table 1). Bromelain was used throughout the rest of this study: it is an enzyme which has been fairly widely used8-12 to demonstrate allo- and autoantibodies against human RBCs. The mouse RBCs were first incubated as a 50% suspension with bromelain at a final concentration of 10 mg ml-1 in phosphate buffered saline for 30 min. The RBCs were washed three times and then incubated at 37°C for 1 h with spleen cells in slide assay chambers13. Rabbit serum as a complement source gave about three times as many, and larger, plaques than normal guinea-pig serum. Only direct plaques were found -a guinea-pig anti-mouse Ig failed to increase the number of plaques at any dilution. They were up to about 0.5 mm in diameter, with many very small plaques.

A number of control experiments confirmed that these plaques were caused by release of Ig from a single central cell. In summary: the plaques did not appear in the absence of complement, or at 4°C, and they were inhibited by guinea-pig and anti-mouse-Ig antiserum to exactly the same extent as mouse anti-sheep RBC plaques, over a range of concentrations of antiserum. At high dilutions of spleen cells a single central cell could be seen in each plaque, and six of these PFCs, when isolated by micromanipulation<sup>14</sup> and stained looked like the basophilic mononuclears which make conventional anti-sheep RBC plaques15. Plaques were not affected by preabsorbing the rabbit complement with bromelain-treated mouse RBCs, showing that they were not caused by a reaction between secreted mouse protein and a cytophilic rabbit-anti-mouse antibody on the treated red cells. They were not caused by nonspecific (Fc) adherence of secreted Ig to treated RBCs as immunisation with sheep RBCs which produced appsoximately 10° anti-sheep PFCs per spleen, did not increase the number of plaques on bromelain-treated mouse RBCs. Also high concentrations of normal mouse serum in the assay mixture did not inhibit plaque formation.

Table 1 Numbers of plaques against bromelain-treated CBA mouse RBCs in various lymphoid tissues

BALB/c mice¶	8 weeks	6	Spleen	1,400 (680–1,920)
CBA mice**	8-10 weeks	4	Spleen	206,000 (147,000-272,000)

<sup>\*</sup> This is a summary of many separate experiments.

CBA mice were treated in various ways to try and increase the number of PFCs in their spleens against isologous erythrocytes which had been incubated with bromelain. The following treatments did not increase the number of plaques significantly over a period of one week: injection of allogenic red cells or spleen cells, injection of isologous cells in Freund's complete adjuvant, a single injection of 10° rat RBCs. A dramatic rise in the number of plaques was, however, induced by a single intraperitoneal injection of 50 µg of lipopolysaccharide (LPS) from Escherichia coli strain 0128:B12 (Table 1). These plaques peaked at 2-3 d then returned abruptly to normal background levels (in preparation).

Against what antigens are these antibodies directed? There are two broad possibilities: either they react with entirely new antigenic determinants created by the enzyme treatment, or they are directed against antigens which are present within the normal RBC. The first alternative seems

to be ruled out by two findings. First, bromelain-treated mouse RBCs provoke little or no increase in the number of plaques on similar target cells when injected into mice (Table 2). In other words, the enzyme treatment has not converted mouse RBCs into grossly foreign particles. Second, rats injected with normal mouse red cells respond by producing both increased numbers of PFCs (Table 2) and high antibody titres (Table 3) against bromelain-treated mouse RBCs. This shows that the antigens on the surfaces, of such treated cells do form part of the normal mouse RBC.

What does the bromelain treatment do to the RBCs to allow mouse lymphoid cells to cause their lysis? Again there seem to be two possibilities. The enzyme may make the RBCs more fragile and able to be lysed by lower affinity, or fewer, autoantibodies. Alternatively, the bromelain may expose some component(s) normally not available to the antibody, which are, however, revealed during normal

Table 2 Numbers of PFCs in the spleens of mice and rats injected with normal or bromelain-treated mouse RBCs

Experiment No.	Test animals species (+No.)	RBCs injected	Days after injection	PFCs per spleen ( BRBCs*	±s.e.) against NRBCs*
1	CBA mice (3)	3×108 BRBCs*	4†	$4.056 \pm 80$	NT‡

In experiment 1, RBCs were injected intravenously, and in experiments 2 and 3, intraperitoneally.

<sup>†</sup> Plaques were counted in a fraction of a spleen cell suspension (usually 1/40). The total number of cells per adult mouse spleen has been assumed to be 10<sup>8</sup> throughout this table.

<sup>‡</sup> These four mice, and the mice of five other strains below it, were all assayed on the same day against the same preparation of bromelain-treated mouse RBCs. The sensitivity of the assay appeared to vary from day to day, and was low on this occasion. There was no significant difference between plaque numbers on isologous or allogeneic treated RBCs.

<sup>§</sup> A pool of tissues from three 8-week-old mice was tested in each case.

<sup>||</sup> In a separate experiment, three 6-month-old NZB females had 9,100, 12,000 and 22,400 PFCs per spleen.

<sup>¶</sup> These mice were taken from strictly isolated germ-free conditions.

<sup>\*\*</sup> Assayed 2 d after 50 µg LPS (intraperitoneal injection).

<sup>\*</sup> BRBC, Bromelain-treated CBA mouse RBC; NRBC, normal CBA mouse RBC.

<sup>†</sup> In this experiment there was also no significant response on days 1, 2 or 7 after injection.

<sup>‡</sup> NT, Not tested. In similar experiments where spleens from normal mice or mice immunised with normal or bromelain-treated RBCs were tested, no plaques were found on normal target RBCs.

breakdown of the erythrocytes either in foreign species (rats) or in mice. This latter explanation is supported by results of absorption of serum from rats immunised with normal mouse RBCs (Table 3). Absorption with bromelaintreated mouse RBCs preferentially lowered the titre to similarly treated target RBCs without much affecting the titre to normal mouse RBCs, and vice versa. This seems to show that anti-bromelain-mouse RBCs and anti-normalmouse RBC antibodies are different populations. Similarly, rats immunised with normal mouse RBCs had more plaques on normal than on bromelain-treated mouse RBCs, again showing that the treated cells are not merely a more sensitive indicator of all antibody which lyses normal cells; they seem to have different antigenic surfaces.

Attempts to demonstrate plaques on isologous RBCs in chicken and sheep have yielded none so far with either normal or bromelain-treated RBCs. Normal rats had less than 30 PFCs per spleen on treated or untreated rat RBCs, but approximately 8,000 PFCs were found in the spleens of LPS-stimulated rats tested against bromelain-treated rat RBCs. It is interesting that rats do have a high normal plaque level to bromelain-treated mouse RBCs (Table 1): possibly mouse and rat RBCs share common internal antigens which are more difficult to reveal by enzyme treatment of the rat RBCs.

The numbers of plaques against bromelain-treated isologous RBCs in the spleens of normal mice is more than an order of magnitude higher than the 'background' level described by many authors against highly immunogenic foreign erythrocytes. This suggests an ongoing response to breakdown products of autologous RBCs, producing antibody which may assist removal of effete cells. The idea that the antigen comes from within rather than from crossreactive environmental stimuli is reinforced by the fact that germ-free mice had similar plaques (Table 1).

Table 3 Absorption of rat-anti-mouse RBC serum with normal or bromelain-treated mouse RBCs

Serum pool	Days after injection*	Absorbed with†	Titre‡ against mouse RB Normal Bromelain-treat		
	•		TOTTILL	Bromeiam-treated	
1	4	- MANAGAMAN	256	256	
		Normal RBCs	< 8	256	
		Bromelain RBCs	128	< 8	
2	6		1.024	4,048	
		Normal RBCs	32	760	
		Bromelain RBCs	256	32	
3	7	Waterlands .	128	512	
		Normal RBCs	< 8	256	
		Bromelain RBCs	128	< 8	

\* Each serum is from a pool of three Lewis rats injected intraperitoneally with mouse RBCs. Antigen dose was  $6 \times 10^8$  RBCs for sera 1 and 3, and  $2 \times 10^9$  for serum 2.

Absorptions were done by mixing 0.5 ml of serum, diluted 1:8, with 0.2 ml of normal or bromelain-treated mouse RBCs. The mixture was incubated for 15 min at 37° C, then the RBCs removed

by centrifugation. This was repeated twice.

‡ Titres are reciprocals of 50% haemolytic and point, using rabbit complement (final dilution 1:20) and RBCs at a final dilution of 0.5%.

This work raises two further questions about tolerance to autologous erythrocytes. First, why is tolerance to the surface of untreated RBCs so much more 'complete', in that relatively few plaques can be found on such targets? This may depend on an earlier confrontation between 'external' RBC antigens and the developing host immune system. The life span of mouse RBCs is 20-45 d (ref. 16), so large numbers of degenerating cells might not be available to act as antigen until 1-2 weeks after birth, while intact RBCs would be present much earlier. Second, why do plaque

numbers stabilise at about 5,000 per spleen (in adult CBA mice) when there is presumably ample antigen available, as RBCs degenerate, to push the response still higher? Even large doses of bromelain-treated RBCs will not increase this number much (Table 2). It seems possible that an equilibrium is maintained between constant antigen stimulation and some suppressor mechanism. This view, which has important implications for self-tolerance, is supported by recent experiments (data in preparation) showing that injection of normal mice with antilymphocyte serum will increase the numbers of plaques in their spleens against bromelain-treated isologous RBCs.

I thank Sue Fordham for technical assistance, Dr J. Watson of the Salk Institute for suggesting and supplying the bromelain, and Linda Pilarski, Kevin Lafferty and Ian Ramshaw for discussions.

Note added in proof: Since submitting this paper I have read the article by Detleer and Edginton (Clin. exp. Immunol., 16, 431; 1974) which describes similar numbers of PFC on bromelain-treated mouse erythrocytes from NZB mice.

# Inhibition of rat lymph node cell cytotoxicity by hepatoma-associated embryonic antigen

One feature frequently accompanying malignant transformation is the re-expression of embryonic characteristics, and the presence of tumour-associated embryonic antigens has been demonstrated on a wide range of experimental and human tumours1-5. Studies in our laboratory, using aminazo-dyeinduced rat hepatomas, have shown that these re-expressed antigens are detectable on cells derived from 14-16-d-old rat embryos, but not cells from adult rat tissue1,8 and in vitro microcytotoxicity tests have revealed that rats bearing transplanted hepatomas exhibit a cell-mediated immune reaction against the embryonic antigen (EA)6.

Here we present results which demonstrate that embryonic antigen isolated from two rat hepatomas is capable of inhibiting the cytotoxicity of lymphocytes specifically sensitised to

<sup>\*</sup> Hepatoma D23 associated embryonic antigen added per  $5 \times 10^5$  LNC (µg protein). † P = <0.1 ‡ P = <0.05 § P = <0.01 ¶ P = <0.001.

embryonic antigen component against hepatoma cells *in vitro*. This mechanism is similar to that shown for the individually distinct hepatoma-specific antigen<sup>8</sup>. The relevance of our findings to the modification of tumour growth *in vivo*, and to antigenic expression on human tumours is also discussed.

Our investigation was designed to evaluate whether in a model *in vitro* system, hepatoma-associated EA had the capacity to interfere with lymphocytotoxic reactions. For this purpose, EAs were isolated following sequential fractionation of the soluble cytoplasmic protein fraction of homogenates from two transplanted hepatomas (D23 and D30) as previously described<sup>1,7</sup>. These procedures make possible the recovery of an antigenic fraction which by conventional criteria seems homogeneous although most recent studies indicate that this material represents at least two distinct, but co-purifying, macromolecules; one being a protein component of molecular weight between 65,000 and 70,000 and the other being a glycoprotein of lower molecular weight (M.R.P., and Z. Tökés, unpublished). The

final EA preparations from hepatomas D23 and D30 retain the capacity to neutralise the membrane immunoflurescence staining of viable tumour cells by multiparous (MP) rat sera which have been shown to contain antibody directed against cell surface-expressed EA<sup>1,7</sup>.

Hepatoma D23 and D33 cells were cultured as monolayers in Eagle's minimal essential medium (MEM)+10% calf serum, and cells obtained following trypsinisation of whole 14-d-old rat embryos were grown in Waymouth's medium+10% foetal calf serum. For lymphocytotoxicity tests, tumour or embryo cells were plated in the wells of Microtest II plates (Falcon) at a concentration of 100-200 cells per well in Eagle's MEM+10% calf serum, and incubated for 24 h at 37° C to allow adherence. MP lymph node cells (LNC), obtained from the cervical, axillary and mesenteric lymph nodes were taken from rats having had three or more pregnancies and which were pregnant at the time of assay. Tumour-immune LNC were obtained from rats which had received three or more  $\gamma$ -irradiated (15,000 rad)

hepatoma D23 grafts, followed by challenge with  $5 \times 10^5$  viable tumour cells at monthly intervals. Aliquots (0.4 ml) containing  $5 \times 10^6$  LNC were incubated at  $37^{\circ}$  C for 60 min with 0.2 ml volumes of EA at various concentrations or in control tests, with medium alone (0.2 ml aliquots MEM). LNC were sedimented at 120g for 5 min and suspended in 2 ml MEM.  $5 \times 10^5$  LNC (0.2 ml volume) were added to each of eight wells in Microtest II plates and after 60 min foetal calf serum was added to a concentration of 10% in each wall. After incubation for 48 h at 37° C any remaining adherent tumour cells were washed, fixed, stained with Gentian violet and counted.

Table 1 (tests 1-5) illustrates the effect of pretreating MP or D23-immune LNC with hepatoma D23 EA. Previous incubation of 5×10<sup>5</sup> MP LNC with 12.5 µg D23 EA reduced their cytotoxicity from 75 to 3\%, representing a 96\% inhibition of cytotoxicity (Table 1, test 1). This concentration did not, however, reduce the cytotoxic effect shown by LNC from hepatoma D23-immune animals for plated hepatoma cells (Table 1, test 1). Comparable results were obtained in a subsequent experiment (Table 1, test 2) again indicating that D23 EA, at concentrations which inhibit MP LNC cytotoxicity does not affect the cytotoxicity of D23-immune LNC. These findings give further evidence demonstrating that the tumourspecific antigen, present on these aminoazo dye-induced rat tumours and against which tumour-immune LNC exert their cytotoxic effect, is a distinct component from the tumourassociated EA. Tests 3-5 (Table 1) exemplify further data showing the inhibitory effect of D23 EA on the cytotoxicity of MP LNC, and in test 6 (Table 1) the cytotoxicity of MP LNC for 14-d rat embryo cells is also reduced following previous exposure to hepatoma D23 EA.

In comparable tests, the EA preparation from another transplanted hepatoma (D30) was found to display similar activity to the EA isolated from hepatoma D23 (Table 2). Pretreatment of  $5 \times 10^5$  MP LNC with 40-50 µg of hepatoma D30 EA significantly inhibited their cytotoxicity for D23 target cells (Table 2, tests 1 and 2). This finding, indicative of a cross-reactive nature between hepatoma D23 and D30 EA, is also supported by previous studies showing that the isolated EA preparations had the capacity to neutralise the membrane immunofluorescence staining by MP sera of surface antigens expressed on either D23 or D30 target cells<sup>1,7</sup>. A variability in EA expression or specificity, however, was indicated in further experiments using MP LNC pretreated with hepatoma D30 EA (Table 2, tests 3 and 4). In these tests, the cytotoxicity of MP LNC for plated hepatoma D33 cells was not significantly reduced by previous exposure to D30 EA at a concentration of 50  $\mu g$  per 5  $\times$  10<sup>5</sup> LNC.

Previous studies have established the existence of two distinct neoantigens expressed at the cell surface of chemicallyinduced hepatomas. These antigens have been differentiated into a tumour-specific component and an embryonic component by several criteria<sup>1,9</sup>. Thus, MP rat serum was shown to block, at the level of the target cell, MP LNC cytotoxicity for hepatoma cells, but was not capable of blocking tumourimmune LNC cytotoxicity for target hepatoma cells. The reactivity of tumour-immune rat LNC for 14 d embryo cells was, however, effectively prevented by MP serum. These results suggest that the host's cellular immune reponse is manifested by two separate populations of sensitised lymphocytes. In our study a similar differentiation between the two neoantigens is shown; MP LNC cytotoxicity for hepatoma cells was inhibited at the effector cell level by hepatomaassociated EA, but this treatment did not affect the cytotoxicity of tumour-immune LNC for hepatoma cells. The involvement of hepatoma-associated EA in eliciting a tumourrejection response is less clear. Immunisation of rats with foetal tissue failed to induce protection against low dose hepatoma cell challenge10. Similar results have been found using other tumour systems11,12, although embryo immunisation has been shown to induce protection against SV40-induced hamster tumours13,14 and 3-methylcholanthrene-induced mouse, rat

and guinea pig sarcomas<sup>15-17</sup>. The failure of embryonic antigens to induce an effective tumour-rejection reaction may be due to the stability, and/or transient appearance of the antigen on the embryo cell surface<sup>1,3,13</sup>; alternatively the route of administration together with the immunising regime and effective EA dosage may greatly influence the eventual immunological response.

Our findings are relevant to studies on human tumours as the embryonic antigens detected by microcytotoxicity tests on carcinogen-induced rat mammary<sup>6</sup> and colonic carcinomas<sup>18</sup> as well as spontaneously arising rat mammary carcinomas and sarcomas6 show organ-type specificities comparable with those identified on many human tumours19 and by analogy the latter may also be re-expressed embryonic antigens. It has further been demonstrated with a limited number of human tumours that antigen mediated inhibition of lymphocyte cytotoxicity may be one mechanism by which a growing tumour evades host immunological control<sup>20,21</sup>. Recent studies showing the presence of hepatoma-associated EA in the serum of tumour-bearer rats implies that such factors may be capable of modifying lymphocytotoxic reactions in vivo (R.C.R., M.R.P., R.W.B., and L.P.S., unpublished), as demonstrated here using in vitro tests.

# Association of mammalian cell death with a specific endonucleolytic degradation of DNA

MAMMALIAN cell death, observed as deterioration of cellular structure or function, has not been characterised at the molecular level. We report here that human and rodent cells treated with several diverse agents which cause cell death as measured by other criteria, had similar distinct patterns of DNA degradation as assayed by alkaline sucrose gradient techniques. The degradation results from cellular metabolism, not from the initial damage produced by the agents. The similarity of the patterns in our results and those of others in a wide range of cell systems suggests that this degradation may be a general mechanism concomitant with, if not a precedent of, mammalian cell death.

Tritiated thymidine (TdR) is a toxic agent when incorporated into the DNA of mammalian cells<sup>1,2</sup>. The soft B radiation of tritium disintegration has a range of about 1 µm and damages primarily the DNA and its immediate molecular environment. The time course of this toxic action as indicated by cell growth kinetics in monolayers of Chang's liver cells (LICH)3 and Chinese hamster lung cells (CHL)4 is shown in Fig. 1. As the growth rate of monolayer cultures thus treated with 3H-TdR slowed down and the cell density eventually declined, intact cells floated into the medium above the attached cells and could be recovered by centrifugation. These floating cells. though normal in appearance by phase microscopy, had a plating efficiency approximately 1% of that of attached cells. After 24 h of exposure to 3H-TdR, LICH cells floating in the medium incorporated only 13% of 14C-leucine and 32% of <sup>14</sup>C-uridine compared with attached cells for a 2-h pulse.

Sedimentation profiles of DNA from floating and attached cells differed (Fig. 2b). The latter was similar to the profiles reported for diploid and aneuploid cell lines<sup>5-13</sup>, and identical to control profiles of LICH and CHL cells (Fig. 2a and e). They consist of a unimodal homodisperse peak estimated by various authors to be between 125S and  $180S^{5-9}$  which, if composed of single-stranded molecules, would correspond to a weight of between  $1 \times 10^8$  and  $5 \times 10^8$ .

The DNA profile of the floating cells, however, was bimodal with a smaller peak between fractions 4 and 6 ( $\sim$  50S) (Fig. 2b). The amount of DNA found in the degraded peak varied with time and metabolic activity. Identical cultures of LICH cells were labelled for 24 h with 0.5  $\mu$ Ci ml <sup>-1</sup> <sup>3</sup>H-TdR and then incubated in either complete medium (CM) or phosphate buffered saline (PBS) for 8 h. This PBS treatment does

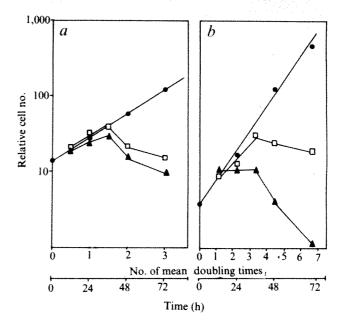

Fig. 1 Relative number of LICH (a) and CHL (b) cells growing in attached monolayers after continued exposure to 0.5 ( ) or 5.0 ( )  $\mu$ Ci ml<sup>-1</sup> of tritiated thymidine (methyl-³H-TdR, 6-15 Ci mmol<sup>-1</sup>) in Eagle's minimum essential medium supplemented with 10% heat inactivated calf serum (LICH) or 15% foetal calf serum (CHL). At times indicated cells were suspended using trypsin and counted using a haemocytometer. •, Control.

not produce toxicity or degraded DNA. Cells were then exposed to fresh medium and incubated at  $37^{\circ}$  C. DNA sedimentation profiles of the floating cells appearing in these cultures were determined 24 and 48 h later. At both times, the DNA of floating cells from cultures whose metabolism was suppressed for 8 h with PBS was less degraded than those incubated in complete medium (Fig. 2c and d). In both cases, however, degradation was more extensive after 48 h than 24 h.

Treatment with toxic agents whose initial action is believed to affect the plasma membrane produced DNA degradation in CHL monolayer cultures. Attached CHL cells, labelled at low  $^3$ H-TdR levels which do not affect growth kinetics, then treated with hypotonic shock, 0.5% deoxycholate or specific CHL antiserum, displayed degradative patterns similar to those induced by  $\beta$  radiation but after shorter post-treatment incubation (Fig. 2f-h). After 5 min of hypotonic shock or deoxycholate treatment, immediate lysis showed the DNA of treated cells was intact, but incubation at  $37^{\circ}$  C in

complete medium for 60 min and 55 min, respectively, produced extensive degradation (Fig. 2f and g). Similarly, the DNA of cells treated for 60 min at 37° C with medium containing a 1:500 dilution of specific CHL antiserum after the method of Shipley et al.10 was also degraded into similar patterns.

Patterns of DNA degradation similar to those in Fig. 2 have been observed in various mammalian cell populations exposed to several toxic agents. Table I lists observations of DNA degradation in experimental systems described here and similar patterns observed by others. Several important conclusions can be drawn: (1) DNA is degraded in both diploid and aneuploid cells after trauma; (2) the decay of <sup>3</sup>H-TdR is not necessary for degradation since Lett et al.<sup>5</sup> and Wheeler et al.6 used non-dividing, unlabelled diploid cells;

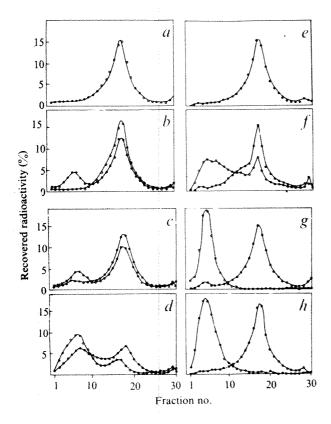

Fig. 2 DNA sedimentation patterns for cells which have received treatment with various toxic agents with and without post-treatment incubation. Cells attached to glass or plastic Petri dishes were labelled with tritiated thymidine (methyl-3H-TdR, 6-15 Cimmol-1, New England Nuclear Corp.), and either treated in monolayer or after suspension by trypsin treatment. After suspension, 2,500-10,000 cells were carefully layered into a lysing solution (0.2 ml, 0.45 N NaOH, 0.5 N NaCl, 0.1 M Na<sub>2</sub>EDTA) on top of preformed 5-20% alkaline sucrose gradients (4.8 ml, 0.1 N NaOH, 0.9 N NaCl, 0.003 M Na<sub>2</sub>-EDTA). After lysing for 4-6 h samples were centrifuged for 15 min at 5,000 r.p.m. followed by 36,000 r.p.m. for 60 min (Spinco 50.1 rotor) at 12-15° C. Gradients were pumped off from the top in 10-drop fractions on to 30 glass fibre filters and counted in a toluene-base scintillation fluid. a-d, LICH cells: a, control LICH cells incubated with 0.1 µCi ml<sup>-1</sup> <sup>3</sup>H-TdR for 16 h; b-d, LICH cells incubated with 5.0 μCi ml<sup>-1</sup> for 24 h; b, with 24 h post-label incubation in complete medium—(•) detached floating cells; ( $\bigcirc$ ) attached monolayer cells—c, detached floating cells with 24 h post-label incubation—( $\bullet$ ) 8 h incubation with phosphate-buffered medium (PBS) followed by 16 h in complete medium or ( ) complete medium (CM) only—d, detached floating cells with 48 h post-label incubation—( ) 8 h incubation with PBS or ( ) CM only. e-h, CHL cells incubated with 0.25 µCi ml<sup>-1</sup> for 16 h: e, control CHL cells, (♠) or after 60 min in CM at 37° C (○); h, treated with 0.5% deoxycholate for 5 min and lysed immediately (♠) or after 55 min in CM at 37° C (○); h, treated with a 1:500 dilution of antiserum¹0 (○) or with complete medium only (♠).

(3) since Nagle and Belli (unpublished data) observed abrupt DNA degradation in isolated CHL nuclei with intact DNA by adding only ATP, the endonucleases need not be induced but may be constituent to the nucleus; (4) in human lymphocytes which are known to be especially sensitive to X rays. DNA appears to be degraded earlier<sup>12</sup> than in cells considered to be less sensitive, such as LICH or diploid CNS cells of the rabbit6 and dog5, and (5) in all cases, cellular metabolism was required to produce degradation.

It seems clear that similar patterns of degradation are common to various mammalian cells after DNA damage, cell membrane perturbation or general toxicity. The degraded DNA in every case had a modal value of between 106 and 107 daltons. Furthermore, since there is little radioactive label in the first two gradient fractions where mononucleotides and oligonucleotides would sediment, degradation must have resulted from an endonucleolytic incision as opposed to exonucleolytic attack which would produce these small fragments. Our results do not indicate whether the incisional attack on the DNA molecule was at random or rather at particular sites that have structural or functional meaning.

The observation of similar patterns of DNA degradation in cells exposed to widely differing types of trauma suggests that this process is a common mechanism associated with the phenomenon of cell death. As is the case for organisms, cells damaged beyond their recuperative capacity may undergo a distinct, non-reversible process which ends coherent metabolism.

### matters arising

#### Alpine Fault of New Zealand and Gondwanaland reconstruction

GRIFFITHS<sup>1,2</sup> has proposed two reassemblies of Gondwana fragments in the south-west Pacific, including New Zealand and the surrounding complex of submarine ridges and plateaux. Both recontructions are based essentially on bathymetric data, the salient difference in the later, revised version being a 250 km eastward displacement of Antarctica relative to Australia, to create space for the newly incorporated South Tasman Rise and East Tasman Plateau.

In general terms, Griffiths's reconstructions are feasible, and, as they agree in many respects with my own earlier schematic reconstruction<sup>3</sup> of the region, I do not wish to criticise them except on one important issue. This concerns the nature of the Alpine Fault trace in the reconstituted Gondwana landmass. In his original reconstruction, Griffiths<sup>1</sup> achieves a close fit of south-west Pacific continental and quasi-continental crustal segments by introducing a sharp deflection-through some 70°-in the line supposedly followed by the Alpine Fault. In his revised version<sup>2</sup>, the Alpine Fault trace becomes even more complex and describes a neat parabolic curve with bifurcating and reconverging branches. Neither interpretation is consistent with the known geometry and tectonic behaviour of the Alpine Fault, and, in my opinion, both embody misconceptions

arising from a failure to appreciate that dislocation along the Alpine Fault has been accompanied by substantial deformation of the New Zealand crustal segment.

As I have attempted to demonstrate elsewhere3, the distinctive NE-SW trend of the New Zealand landmass and its congruent regional geological strike both relate to New Zealand's evolution, since late Cretaceous times, along the interface between two moving crustal plates. West of New Zealand, the opening of the Tasman Sea has been attributed4 to late Cretaceous and Palaeocene activity of a NW-SE trans-Tasman spreading axis (perhaps an initial westward prolongation of the still active Pacific-Antarctic Ridge), that brought about a rapid north-eastward migration of the continental and quasi-continental crust of Lord Howe Rise and Norfolk Ridge. To the south and east of New Zealand, extension of the south-western Pacific Basin commenced simultaneously5, and Campbell Plateau and Chatham Risetheir free movement to the north-west obstructed by Lord Howe Rise and Norfolk Ridge-were forced northward at a somewhat slower rate.

These differential movements produced, among other effects, large scale sigmoidal flexuring of the broad belt of Palaeozoic and Mesozoic greywacke formations that had accumulated along the margin of Gondwanaland, in the so-called New Zealand Geosyncline<sup>6</sup>. The development of a complex system of NE-SW major shear fractures, the best known of which is the Alpine Fault, marked the culmination of this flexuring. Within the vicinity of New Zealand, the original course of the peripheral geosyncline can legitimately be supposed to have been more or less linear, and it is essential that, in any reassembly of crustal fragments, compensation be made for the crustal distortion that followed the disruption of Gondwanaland. Figure 1 demonstrates that, in such reconstructions, it is not sufficient merely to postulate reverse displacement of crustal segments by the amount of obvious fault offset. Admittedly, the structural unravelling of intensely deformed areas is not easy, but I would suggest that allowance for crustal distortion, as well as dislocation, in the New Zealand region would simplify and rationalise the form of the Alpine Fault trace in reconstructions such as those of Griffiths.

DAVID J. CULLEN

DR GRIFFITHS REPLIES-Cullen's main point seems to be that the Alpine Fault is not the only deformation of New Zealand which occurred during seafloor spreading and that it is therefore insufficient simply to reverse the observed 480 km offset in reconstructions. I have, however, always accepted this point; it is not explicitly stated but is quite obvious from the diagrams in my 1971 article (Nature, 234, 203-207). I have suggested (Nature, 235, 83-86; 1972) that the total offset of the New Zealand Geosyncline is some 1,200 km, which is partly taken up by the Alpine Fault, and the rest by 'bending and stretching of the geosynclinal axis". Though detailed structure is not shown, the general concept is quite clear from the figures. I have also referred to the 'Alpine Fault Zone' as distinct from the specific fault (Nature, 249, 336; 1974); it is the former which is indicated on the figure. I have in preparation an enlarged version of my Alpine Fault model, but as it involves over 30 dia-

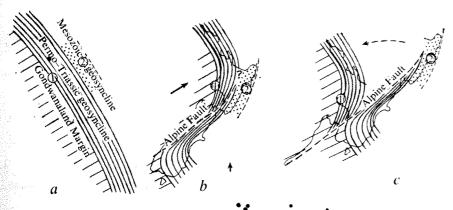

Fig. 1 Schematic reconstruction of the New Zealand region. a, Postulated distribution of linear geosynclinal belts along the eastern margin of Gondwanaland. Numerals represent approximate sites of Egmont (1) and Hawke Bay (2), b, Present day New Zealand structure. Trend and length of arrows indicate direction and rate of Cainozoic crustal movements. c, Spurious Gondwanaland reconstruction (compare Griffiths<sup>1,2</sup>) achieved by simple reversal of the Alpine Fault displacement and realignment of the Permo-Triassic geosynclinal belt. Note that artificial rotation of the Alpine Fault (broken arrow) places Hawke Bay some 500 km north of Egmont, and duplicates a section of the Permo-Triassic geosyncline.

grams, it will be offered for publication elsewhere. In this model, many of the faults in Southland (for example, the Livingstone and Hollyford faults) are related directly to the distortion which Cullen rightly points out has occurred.

In short, I agree with Cullen's observations that further evidence for crustal distortion should be sought, and that the Alpine Fault with its 480 km offset is only part of the whole story. Apart from this, however, his paper seems to offer nothing positive, and indeed fails to recognise that I have always accepted that such distortion must have occurred. If he has a different regional reconstruction, or a detailed model for the deformation of New Zealand, it might help if this was illustrated by accurate diagrams rather than sketches.

University of British Columbia

### Dendrochronology and <sup>13</sup>C content in atmospheric CO<sub>2</sub>

FARMER and Baxter¹ have published δ¹³C values from the wood of tree rings, indicating a decrease over the last 70 yr, which they attribute to the CO₂ increase of the twentieth century. The result, in general, was expected but some implications seem to be questionable, as we can conclude from our results²-⁴.

When studying the decrease of <sup>13</sup>C in atmospheric CO<sub>2</sub>, wood samples have to be selected very carefully. Samples selected from industrial or forest areas do not give reliable information about the average atmospheric composition<sup>5</sup>. The ideal recorder would be a free-standing tree on a small island far out in the ocean. We analysed tree rings of 10 trees (Fig. 1) and recognised large individual variations both in the absolute data and in the trend.

The processing of the samples is also important. It is well known that a network of resin channels permeates the wood tissue and contains soluble organic matter which cannot be correlated to the age of the wood structure. Furthermore, the components which form the wood, cellulose and lignin, have different isotopic compositions. We found a difference between the  $\delta^{13}$ C values of cellulose and lignin prepared from the same wood, of almost 3 ‰. The ratio of lignin to cellulose cannot be expected to remain

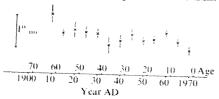

Fig. 1 Average relative <sup>13</sup>C decrease in the wood (cellulose) of tree rings during the past <sup>70</sup> yr obtained from 10 freestanding trees; Quercus robur (4), Q. petraea (1), Pinus maritima (2), Q. lusitanica (2), Platanus acerifolia (1). Each point represents a 5-yr average.

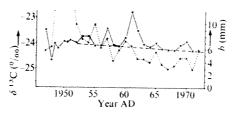

Fig. 2 Platanus acerifolia (Azores), showing correlation between ring width, b (dotted line) and  $\delta^{13}$ C (PDB) values (solid line).

constant over the lifetime of the tree<sup>8</sup>, so that the preparation of one pure component is necessary. The chemical preparation of cellulose<sup>7</sup>, if done carefully, does not introduce artificial isotope fractionation.

Another complication arises from the fact that there are normally considerable variations in the <sup>13</sup>C content even within one single tree ring of the order of 1‰. That demonstrates clearly the necessity for matching wood taken from the same year but from different positions on the tree. Furthermore, a correlation between ring width (climate ?) and <sup>13</sup>C content has been observed (Fig. 2).

Finally, concerning the interpretation of <sup>13</sup>C curves with respect to excess CO<sub>2</sub> in the atmosphere, it has to be taken into account that the exchange rate of isotopic CO<sub>2</sub> molecules between the atmosphere and the oceans is faster than the net flux of CO<sub>2</sub> into the oceans (H.D.F. and L.W., and K. Wagener and H.D.F., unpublished). This means that without any further information it is not possible to draw any direct conclusions from <sup>13</sup>C measurements about the actual CO<sub>2</sub> excess in the atmosphere, even if the fractionation factors are constant.

A detailed presentation of our results will be given elsewhere.

DRS FARMER AND BAXTER\* REPLY—The data of Freyer and Wiesberg¹ represent a welcome and significant contribution to the preliminary study of  $\delta^{13}$ C trends in recent wood. It is gratifying that their results agree closely with our own²

(Fig. 1) and thereby seem reasonably to negate their criticisms of the different procedures. Although suggestive of a common temporal trend in  $\delta^{13}$ C, their presentation of data as average deviations over 5-yr periods for 10 trees of differing species and locations does not permit inspection of the individual  $\delta^{13}$ C trend for each tree. They thus preclude any precise assessment of discrepancies caused by variations in species or location. Such discrepancies were, for example, noted in our oak and larch data but, of course, are now obscured by the averaging process.

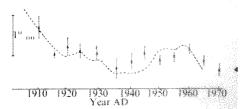

Fig. 1 Comparison of  $\delta^{13}$ C trends in twentieth century wood. Dotted line, mean of data from the same UK oak and larch samples as we reported previously. The points and accompanying errors are those of Freyer and Wiesberg representing the averaged data on 10 selected trees.

In response to specific comments about procedure we would assert that, first, the European larch was indeed selected from a free-standing and exposed situation and yet showed a similar δ13C trend to the forest oak. Second, the dangers of inducing fractionation or contamination during cellulose extraction seem comparable to the possible risks in using whole wood. Third, concerning the ever present difficulty in obtaining a representative biospheric sample, the suggestion of Freyer and Wiesberg. though admirable in intention, could well result in a logistical problem of overwhelming proportions without guaranteeing the comparable representativeness of every sample.

Extreme caution in data interpretation was initially urged by us, and Freyer and Wiesberg are correct to reinforce this view. Nevertheless, it remains undeniable that during the first 20–30 yr of this century, recorded levels of  $\delta^{13}$ C show an unexpected decline which could not have been caused even by complete retention of all the fossil CO<sub>2</sub> introduced into the atmosphere. Furthermore, the CO<sub>2</sub> levels deduced from our  $\delta^{13}$ C values for 1900–1920 agree well with those of Callendar's exhaustive summary<sup>3</sup>, leading to the postulate of an additional biogenic source of CO<sub>2</sub>.

#### Mononuclear cells killing Cryptococcus

DIAMOND in his report<sup>1</sup> has presented by no means a new discovery; Aronson and Kletter2 have already demonstrated the in vitro killing of extracellular Cryptococcus neoformans by rabbit monocytes even in presence of normal rabbit serum. Monocytes do not necessarily require the presence of specific antibody to kill cryptococcus extracellularly but rather the presence of suitable opsonins which presumably enable the pseudopodia of the phagocytes to adhere firmly to the capsule of this fungus. Rabbit, guinea pig and human sera (but not mouse sera) seem to possess opsonins which are able to induce the phagocytosis of the cryptococci as well as the development of monocyte rings around them which, in turn, can destroy the enclosed parasites.

I feel that Diamond errs when he states that activated macrophages " provided a preferentially favourable medium for intracellular growth of the fungus" and infers that host macrophages may be involved in the dissemination of the disease3. He drew these conclusions from experiments with human monocyte-derived macrophages activated in in vitro conditions with streptokinase-streptodornase and kept in culture for 3-7 d before inoculation of cryptococci. I have observed the extracellular and intracellular killing of cryptococci by murine macrophages (activated either nonspecifically or specifically) in certain conditions: that is, by in vivo-activated adherent cells kept in in vitro culture for only 2 h before the inoculation of cryptococci in the presence of normal rabbit serum4,5; these sera lacked agglutinating capacity. Prolonged in vitro incubation of activated macrophages resulted in a corresponding decrease of their intracellular killing activity.

If phagocyte spreading of the infection in the intact host was involved, as suggested by Diamond, then the administration of drugs like cortisone which are known to promptly depress phagocyte numbers in general should localise this infection. On the contrary, however, it is known that cortisone treatment results in the dissemination of this disease6.7. Diamond's interpretation, that the extracellular killing of cryptococci in his system where 10 µg ml<sup>-1</sup> of cytochalasin B was included to prevent phagocytosis of organisms, was due to antibodydependent killing by monocytes, may not be exactly correct.

Egg-white lysozyme and various cationic proteins from rabbit polymorphonucleocytes are fungicidal for C. neoformans's and the addition of

2-10 µg ml<sup>-1</sup> of cytochalason B facilitates the release of lysosomal enzymes from macrophages by exocytosis<sup>8</sup>. Thus the extracellular killing of cryptococci by enzymes released from monocytes simply as a result of their incubation with cytochalasin B is a possibility which cannot be dismissed by the data Diamond presented.

DR DIAMOND REPLIES—Sethi seems to have overlooked or misinterpreted the major differences between my studies and those of Aronson and Kletter1. In contrast to their studies, the fungicidal mechanism which I described requires effector cells which are not necessarily monocytes, as well as specific antibody, but no heat-labile The heat-labile opsonins opsonins. which Aronson and Kletter referred to are almost certainly complement components, as detailed in studies of

complement pathways in opsonisation of cryptococci and in the pathogenesis of cryptococcosis2-4 In my study of the possible role of

the role of the classical and alternate

fungicidal activity by non-phagocytic cells, mononuclear cell preparations had 20% or more monocytes mixed with lymphocytes. The effect of heat-labile opsonins was eliminated by heat and the role of other complement components was minimised by the large dilution (1:2,000 or 1:20,000) of antibody. No other serum was present. Unlike the studies of Aronson and • Kletter, • fungicidal activity occurred only in the presence of antibody, even

when effector cells were obtained from four donors who had positive delayed skin tests to cryptococcal antigen.

Sethi's assumption that monocytes are responsible for the fungicidal activity is not warranted. In fact, I

suggested an analogy to antibodydependent cell-mediated lysis of mammalian target cells, which is known to occur when all phagocytic cells have been eliminated from effector cell populations'. In subsequent studies, we used lymphoid cells depleted of phagocytic cells by incubation with carbonyl iron particles and passage through a magnetic field modified from the technique of Lundgren et al.6. Only 43.5% of a crytococcal inoculum survived after incubation for 4 h. This fungicidal activity occurred only in the presence of antibody (R.D.D. and A. C. Allison, unpublished).

The role of the macrophage in immunity to cryptococcosis is another issue entirely, and one which is too complex to be thoroughly discussed here. In any case, corticosteroids have a wide range of effects, and I am surprised that Sethi assumes that depression of the number of phagocytes is the overriding corticosteroid effect on the immune response.

I did not study the mechanism of antibody-dependent killing and certainly did not assume that fungi were killed by monocytes, as Sethi states. Monocytes may well have this killing capacity, and lysosomal enzyme release may well be important. Preliminary studies with my coworkers (R.D.C., C. Cardella, P. Davies, and A. C. Allison, unpublished) have shown, however, that supernatants rich in lysosomal enzymes released from macrophages7 do not kill cryptococci and that cryptococci induce detectable specific lysosomal enzyme release only in the presence of heatlabile opsonins. Anti-cryptococcal antibody augments this release only slightly, if at all.

I regret that Sethi has misunderstood my work, but appreciate the opportunity to rectify the inadvertent omission of reference to the work of Aronson and Kletter, which was called to my attention after my manuscript appeared.

### CHARLES C THOMAS - PUBLISHER

PROTEIN NUTRITION edited by Henry Brown, Harvard Medical School, Cambridge, Massachusetts. (17 Contributors) Newer rapid solid phase methods for peptide and protein synthesis are clearly presented with meaningful data to compare results with older classic methods of organic chemistry. These methods are tools for those working in some of the most advanced and important areas of medicine: synthesis of hormones, antimetabolites and many biologically active peptides. Complementing these basic studies is a detailed review of specific methods for synthesis of a globin peptide. Crucial data concerning the amount of each amino acid required, both dispensable and indispensable for proper nutritional balance are detailed with concise tables for rapid but thorough reference. '74, 256 pp., 62 il., 36 tables, \$16.75

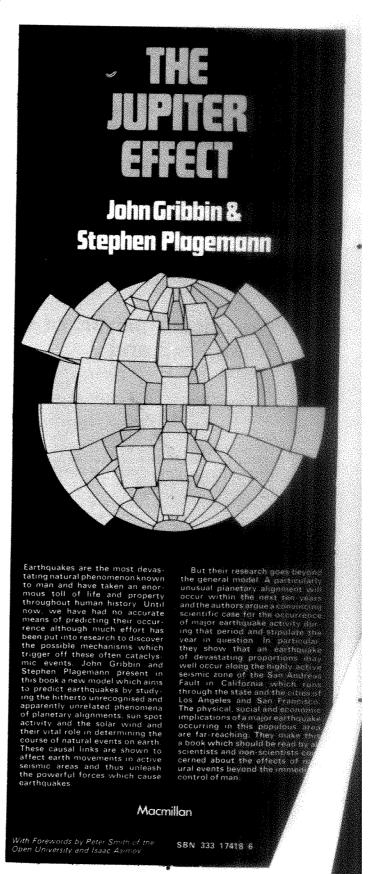

**ECOPHYSICS:** The Application of Physics to Ecology by James Paul Wesley, Univ. of Missouri, Rolla, Missouri. Written primarily for physicists and mathematicians interested in theoretical ecology, this book should also interest ecologists, biologists, environmentalists and exobiologists. In applying the rigorous concepts of physics to ecology, certain special definitions are introduced. Topics discussed include all possible sources of energy, thermodynamics, the competition of machines with carbon-based life, the stability of the carbon cycle in the ecosphere and the territorial origin of human conflict. '74, 368 pp., 39 il., 7 tables, cloth-\$19,75, paper-\$13,75

LIVING CLOCKS IN THE ANIMAL WORLD by Miriam F. Bennett, Colby College, Waterville, Maine. This is a discussion of the biochronometers of crabs, bees, worms, molluscs and amphibians, written for biologists and other scientists who are interested in timing phenomena in organisms and the relationship of environmental factors to living clocks. Students and laymen will also find the book readable because of its well defined terms and many illustrative examples of organismic time-keeping. The author provides an historical overview of the study of living clocks and the state of research at the present time. Leading investigators and their contributions to biochronometry are cited, and the value of the biological knowledge of time to other disciplines and interests is noted. An extensive bibliography is also presented. '74, 236 pp., 53 il., \$11.75

BIRTH DEFECTS AND FETAL DEVELOPMENT: Endocrine and Metabolic Factors edited by Kamran S. Moghissi, Wayne State Univ., Detroit, Michigan. (22 Contributors) This volume clarifies many unanswered questions regarding human reproduction; it reviews and updates the current knowledge and outlines areas which deserve future exploration. The relationship between maternal nutrition and fetal development, the influence of endocrine and environmental factors on fetal growth and well-being, the recognition of factors leading to the respiratory distress syndrome, prenatal detection of congenital and hereditary disorders, and genetic counseling are among the subjects discussed. '74, 352 pp., 94 il. (1 in full color), 45 tables, \$24.50

#### The Interpretation of Multiple Observations

F. H. C. Marriott

November 1974, x+118 pp., £3.50/\$9.00.

0.12.473450.2

There are two main stages at which mistakes occur in the numerical analysis of multivariate datain the choice of a particular method of analysis, and in the interpretation of the results thereby gained. The book provides a critical examination of the most important available numerical methods, relating them to the types of data for which they are suitable, explaining the questions they are trying to answer and the assumptions they involve. In discussing the classical techniques of discriminant analysis, factor analysis, principal components and canonical analysis, and more recent developments in the fields of cluster analysis and scaling methods, extens in hid on the association. developments in the fields of cluster analysis and scaling methods, stress is laid on the practical aspects of the examined methods, while mathematics is kept to a minimum. This work will be of great value to all scientists needing to analyse multivariate data, including biologists, geologists, soil scientists, psychologists and biomathematicians.

Here are the second and third volumes in this critical review of the organometallic compounds of all the elements, compounds which are attracting increasing interest all over the world. In these reference volumes the author takes account of the international literature on the subject up to the end of 1972. These volumes cover elements from Group 4A and Group 4B: Volume 2 includes a major chapter on silicon and a minor chapter on titanium, zirconium and hafnium, while Volume 3 deals with germanium, tin and lead. Each chapter provides a complete review of all aspects of the organocompound in question, together with critical comments on the relative importance, merits and demerits of the methods of analysis applicable.

#### The Physical Chemistry of Dye Adsorption

I. D. Rattee and M. M. Breuer

November 1974, xiv+324 pp., £8.60/\$22.25.

0.12.582550.1

Here is an up-to-date work which brings together important information on experimental data produced by current research and relates it to general scientific knowledge regarding surface phenomena. Thus it is able to present a more unified approach to the dye adsorption process than have previous books on the subject, at the same time defining more clearly the role played by research in relation to technological demands. This leads to a treatment which is much more informative to the research chemist and enables the main investigation groups in general science, medical and dye/textile polymer research, to be considered together. This volume should appeal to a wide audience—including students and researchers in cosmetic, colour, textile and polymer chemistry, surface and colloid chemistry, histology, food science, medicine and ecology and in many other areas concerned with interfacial phanomena.

## Triangle of parallel ideas

Leibniz in Paris 1672-1676: His Growth to Mathematical Maturity. By Joseph E. Hofmann. Pp. xi+372. (Cambridge University: London, June 1974.) £8.50.

WHEN Leibniz arrived in Paris in March 1672 as the travelling companion of Melchior Friedrich von Schönborn he knew little of the mathematics of the time. But under the guidance of Huygens he made rapid progress and over the next four years conceived his decisive ideas in mathematics, bringing them to a degree of completeness that allows us to see all his later research as elaboration and development. Leibniz would have liked to remain permanently in Paris but having failed to obtain a post there he reluctantly moved to Hanover in October 1676, where he took charge of the Library. It is a testimony to his irrepressible optimism that despite the uncertainty regarding his future Leibniz succeeded, during his last year in Paris, in attaining his greatest mathematical achievement: the invention of the calculus.

Professor Hofmann's brilliant account of these fruitful years in Paris, originally published as Die Entwichlungsgeschichte Leibnizschen Mathematik während des Aufenthalts in Paris (1672-1676), is now presented in a new version, carefully revised by the author and competently translated by A. Prag and D. T. Whiteside. The story is told with the thoroughness, meticulous documentation and clarity of exposition we have come to expect from the lamented master in the field of Leibnizian mathematics. There are three indexes. The first is a chronological index giving a register of all letters or original publications in contemporary periodicals mentioned in the text or footnotes, locations of manuscripts, meetings of learned societies and a checklist of publications in the periodical literature of the time. This is followed by an index of names and works, and a good subject index.

Leibniz's first mathematical discovery in Paris, concerning the summation of infinite series, illustrates two important characteristics of his work, namely the role played by considerations of logic and his preference for methods rather

Gottfried Wilhelm von Leibniz-did not borrow from Newton

than results. Beginning simply with definitions and the axiom of identity, Leibniz obtained from Grégoire de Saint-Vincent's geometrical progression a general method which enabled him to sum the series of reciprocal triangular numbers, a problem proposed to him by Huygens.

Soon after his arrival in Paris, Leibniz made his first visit to London. Although this was not an unqualified success, it marked the beginning of the exchanges with English mathematicians which led eventually to the priority dispute concerning the invention of the calculus. Having appropriated Sluse's tangent rule. Newton maintained that it was the communication of this rule in his own letter that led Leibniz to develop the ideas of the differential calculus. Leibniz always insisted that he had the rule from Sluse, and an excerpt from Sluse's treatise among his papers confirms the truth of this claim. Hofmann effectively demolishes the idea-unquestioned since the suggestion of Tschirnhaus in 1678-of a link between the ideas of Leibniz and those of Barrow. It was not from

Barrow and Newton but from Huygens, Grégoire de Saint-Vincent, Mercator, Gregory and Sluse that Leibniz received his inspiration. When Leibniz met Tschirnhaus towards the end of November 1675, he already possessed his notation for the infinitesimal calculus. It is clear that Tschirnhaus, who had just visited London, could not have transmitted accurate reports of English mathematical methods to Leibniz (even if he had been told anything in detail) for, as his subsequent correspondence shows, he had not really penetrated to any fundamental level of mathematical understanding.

On the documentary evidence so skilfully presented and analysed in this volume, it is clear that Leibniz had truth on his side when he stressed that, as far as methods were concerned, he got nothing from the English. Hofmann's conclusion seems eminently fair: each of the three rivals (Newton, Leibniz and Gregory) achieved his own method; none borrowed or took over, from either of the others, more than certain incidental details.

E. J. Aiton

#### Phloem transport

Transport of Nutrients in Plants. By A. J. Peel. Pp. 258. (Butterworth: London, April 1974.) £4.80.

THE author's name is a truer guide to the content of the book than the title: transport in the phloem is the subject studied in depth. Discussion of transport in the xylem occupies about a tenth of the book. The symplast system is described, perhaps as an afterthought, in one page of the introduction. Transport across membranes or within the cells is mentioned only briefly. Nevertheless, as a book on phloem transport, this is a most useful work that successfully communicates the nature of scientific investigation and explores a system which is of biological interest to both the academic student and the applied scientist.

Although a self contained book in its own right, the author facilitates further reading by signposting the more relevant recent reviews to augment the information he presents, and by citing some original papers. A glance through the contents rapidly conveys the wide range of background provided. I anticipate that the concepts and approaches discussed will not become rapidly outdated. The book would serve well as an introduction enabling the student to proceed with greater in-

**國 HM50 BOOK5** 

sight to the proceedings, shortly to be published, of the Phloem Transport Conference just concluded at Banff, Alberta.

The text contains remarkably few factual errors, especially for a first edition. It also presents a fair assessment of the current balance of opinion and of the problems associated with interpreting experimental data in relation to theoretical (or hypothetical) models. The evidence quoted by Peel shows a distinct personal bias, but this prerogative may be allowed as it is relevant work which advances the line of the arguments. Data are quoted with a high degree of reliability throughout the text. In the case where the results presented did not seem to fit-a table on page 30-I found that the error arose only because the data were condensed from two separate experiments in the original reference.

There is a short section which lacks the high standard of clarity shown in the rest of the book, in which Peel calculates how much energy, compared with that available from metabolism, would be required to drive actively a volume flow through sieve tubes containing fibrils. He implies that such a flow would be driven against some overall pressure difference, whereas a metabolically dependent pumping mechanism might well drive a flow against a viscous resistance in the absence of an overall pressure difference. His calculation is, of course, correct but the purpose and the understanding are obscured.

These two criticisms are, however, on very rare exceptions in the text. For the advanced undergraduate, as an introduction to further study, and as a background to applied biology, the book conveys a clear and realistic appraisal of the variety of approaches and of the disagreements and controversies within the field of phloem transport.

David Aikman

Younger fold belts

Mesozoic-Cenozoic Orogenic Belts. Data for Orogenic Studies. Edited and collated by A. M. Spencer. Pp. xvi+809. (Scottish Academic Press: Edinburgh, 1974.) Published for The Geological Society, London. n.p.

This book tells the reader about some 40 segments selected from fold belts formed since Mesozoic times. Dr Spencer writes in his introduction that the volume is not designed for fireside feading, but 1° rather doubt that. It sets out to provide an objective presentation of what is known about each region; as far as possible the treatment is uniform from sector to sector. The result I find is absorbing and the book rather well suited for the evening fireside. With it one can travel along the

margins of the Indian plate from Turkey to the Macquarie Ridge examining 20 sections on the way. And if you fancy the Pacific, there are 20 segments of circum-Pacific structures laid out for your consideration.

About 100 scientists have contributed to the making of this book. As a beginning, a small group worked out a questionnaire which could be applied to each selected segment. It posed over 300 questions relating to such matters as surface shape, deep structure, and time relationships, and was designed to elicit a series of factual answers. The main mass of the book consists of accounts of 46 segments based on the responses of over 80 experts who replied to the questionnaire. Dr Spencer collated and edited these replies. On his shoulders and on Sir Peter Kent, who chaired the group which initiated the project, and who in the later stages provided the resources which brought it to completion, has lain the main burden of producing this volume. Readers can judge for themselves how successful the work has been. Coming to the completed book as a member of the group who started the project I think the result is impressive. Much effort separates the finished work from the initial proposals of the planning committee and I do not feel that membership of that body prevents me from congratulating Dr Spencer and Sir Peter. By their efforts they have transformed the original idea-Mr Brian Harland's, as I recollectinto a book of 800 solidly packed pages.

Geotectonic theorists can now contemplate systematic accounts of segment after segment of the Mesozoic and Tertiary fold belts of the world in comfort by the fireside. More to the point, the book prevides a useful tool for further research. It supplies what was planned at the outset-data for orogenic studies. It shows that the complexities of mountain chains can be treated in a systematic fashion. The amount of data presented varies from region to region, as is to be expected. More serious is the lack of information from the Soviet Union and the western states of America despite vigorous efforts to fill that gap. The Geodynamics Programme includes, however, a similar but more extensive project which may be expected to compensate for those omissions.

Of particular interest is the opportunity this volume provides for comparisons between the make up of young fold belts and structures formed earlier in the history of the Earth. There is a growing body of evidence which suggests that global tectonics have changed with time. Data such as this should help to show whether or not that view is firmly founded. **J. Sutton** 

### Animals' sticking places . . .

Biological Mechanisms of Attachment. By W. Nachtigall. Translated by M. A. Biederman-Thorson. Pp. viii+194+53 plates. (Springer-Verlag: Berlin and New York, 1974.) DM75; \$30.60.

This book is an oddity. As description in hard engineering terms of the ways in which creatures of all kinds attach themselves to their prey, substrate, or each other, it can have little practical value. So it must be read, presumably, for the enjoyment of seeing how nature's engineering parallels that of man.

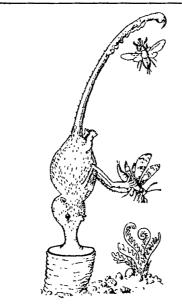

The book is not an exhaustive catalogue (Dr Nachtigall does not describe the flexible limb joints of animals, for example) but it includes devices which hook, grip, clamp, glue, suck or interlock organs or individuals together in permanent or temporary bonds. Any book of this kind is necessarily a list to be dipped into rather than a text to be read from cover to cover, so it is just as well that most of the 712 illustrations are arranged on pages which are opposite their explanations in the text. Where possible, the solutions that human engineers have come up with to meet the same circumstances are described and it is curious how alike many of them are.

Dragonflies, for example, which mate on the wing face problems similar to those of aircraft refuelling in flight, and the mating of the Aedes mosquito (where a perfect alignment of the reproductive tracts must be made and broken in about 14–20 seconds) resembles the 'hard docking' of spacecraft.

Suction seems to be the most widespread attachment mechanism throughout the phyla and about one third of Dr Nachtigall's book is devoted to it. Examples range from the sucking mouthparts of helminth parasites to the suction pads on the feet of the tarsier.

Although arthropods and helminths tend to dominate the book, many old favourites like the pop fastener on the mantle of the squid also appear. The head of the tapeworm, the claw of the arthropod and the Aristotle's lantern of the seaurchin are also rather obvious examples. This indicates a rather subtle drawback of the book: most of the contents, although admirably explained and compared, could probably be guessed by any competent biologist.

There are some surprises—for example, the revelation that no two tissues are ever connected in nature by a third, like a nail or screw—but the merit of the book must remain its value

The fanciful monorhinid, Dulcicauda grisegurell

for directing the biologist to think of the attachment mechanisms of animals in engineering terms rather than as any sort of reference work.

The author makes two curious mistakes. The first (and most serious) is that the text describing the attachment of the sucker organ of the remora does not relate to the series of drawings used to illustrate it—indeed it describes the opposite (and wrong) sequence of events. The second is that the author has placed a charming (but unreal) member of the Monorhina in a section dealing with suction cups when, of course, it uses an adhesive.

### ... placing sticking plants

Mycologists Handbook: An Introduction to the Principles of Taxonomy and Nomenclature in the Fungi and Lichens. By D. L. Hawkesworth. Pp. 231. (Commonwealth Mycological Institute: Kew, 1974.) £5.50; \$14.30.

Most biologists have only a superficial knowledge and understanding of taxonomic procedures, and those with a real feeling for the subject are few in number. This book goes a long way towards bridging the gap between the many and the few. The author is to be congratulated on producing a detailed, accurate and thoroughly readable book on a subject which is often dismissed as dull and uninteresting.

Although the book is essentially a guide to budding taxonomists it has much to say to others who experiment with, and publish data on, fungi and lichens. The need to identify material correctly, often a difficult task with fungi and lichens, and the need to store specimens in accessible herbaria are particularly emphasised; in the past the frequent failure to do this properly has reduced the value of much published work. Topics covered include the collection and preservation of material; taxonomic ranks; the naming and describing of new taxa; nomenclature; information on authorities and herbaria; and information on the abbreviations of the titles of publications not quoted in the World List of B. W. Ferry Scientific Publications.

A somewhat decorative method of dispersal. The fruit and pappus of the thistle Silybum marianum. From The Natural History of New Zealand: An Ecological Survey. Edited by Gordon R. Williams. Pp. xviii + 434 + 40 plates. (Reed: Wellington, Sydney and London, 1973.) £12.95.

#### **Answers to Monod**

Beyond Chance and Necessity. Edited by John Lewis. Pp. xi+141. (Garnstone: London, 1974.) £2.95.

When Jacques Monod, in Chance and Necessity, classed Christians and Marxists, along with witch doctors, as "animists" who attribute a will to nature, a reply was to be expected. These essays, published as part of the Teilhard Study Library, are part of that reply; Beyond Chance and Necessity brings together a number of people who have little in common other than their disagreement with Monod.

Monod argued that our present cultural confusion arises because our ethical beliefs are based on various pictures of the world, in particular the Christian myth, which ascribes a purpose to the Universe and a special role for man in that purpose, whereas our economic existence depends on the scientific world picture, which does not admit explanations in terms of purposes or final causes, and which sees man as the accidental consequence of natural selection acting on random mutation. He urges us to recognise the distinction between 'objective' statements proper to science, and statements of value which cannot be derived from science. The 'principle of objectivity'-the avoidance of teleological explanation in science—he sees as itself a moral commitment, necessary for the practice of science and, therefore, not derivable from it.

Mary Warnock accuses Monod of arguing in a circle. If science is based on the assumption that there are no purposes in the Universe, one cannot then deduce from science that there is no purpose, and no special role for man. Monod's picture of the world is, in fact, quite consistent with God as a 'first cause', who created a world capable of generating life, and who even retains an interest in that world. This argument is taken further from a Christian standpoint by Arthur Peacocke. He argues, by analogy with statistical mechanics, that the randomness of mutation does not mean that there are no laws of evolution; a point made by other contributors, and one I would accept. For a Christian, however, God as a first cause who designed the laws of nature and the initial conditions to hold the potentiality of life and who then let the Universe run, is not enough. Peacocke is critical of the concept of a "God of the gaps", invoked to explain those phenomena which science cannot, because that canelead only to a dwindling role for God. Instead he sees God as imminent in all natural processes, working through the laws of nature and not by suspending them.

My difficulty here is not so much that I disagree with him as that I cannot see what he can possibly mean. If God is simply another name for the laws of nature, then not only is there no need for that hypothesis, there is no need for the term itself.

The defence of Marx is taken up by John Lewis. It is perfectly possible to be a good philosopher without knowing any biology; unhappily, Dr Lewis writes as if he understood biology when it is quite clear that he does not. That gives such an air of insincerity to his essay that I found it impossible to pay serious attention to it. That is a pity, because I think he is right in arguing that Marx and Engles were not animists in Monod's sense. They saw 'dialectical laws' not as a mind or purpose in nature, but as observable regularities in the behaviour of natural systems.

Joseph Needham also comes to the defence of Marxism. He quotes with approval the antimechanist views expressed by Soviet Marxist scientists in the early 1930s. That will not quite do. A few years later, Marxist philosophers, arguing that the gene was an undialectical entity because it controls development without being influenced by it, supported the destruction of biology in the Soviet Union; at the same time, men who believed that the cell is a machine (not, it is true, a clock—more a tape-recorder) were revolutionising biology.

The most interesting essays in the book are written from within evolution theory and molecular biology, by C. H. Waddington and Robin Monro. Waddington was provoked into contributing by a report that Monod has accused him of Lysenkoism. I do not know whether the report is true, but I am glad of the result; if a man is accused of Lysenkoism it does concentrate the mind wonderfully. Waddington gives an unambiguous account of the significance of genetic assimilation. Monro criticises Monod's excessive reliance on molecular concepts in biology. He first argues that the 'central dogma'-that information cannot pass from protein to nucleic acids-is not necessary for the truth of Weismannism. An 'acquired character' is not usually reflected in a changed amino acid sequence in protein, so even if the central dogma were false, most acquired characters could not be transmitted. Monro goes on to argue that the dogma is not sufficient either, because some kind of germinal selection may produce Lamarckian effects (the same idea is worked out in more detail by Waddington).

The main difficulty in assessing this controversy is that at least two separate issues are being confused. The first is the relationship between science and

ethics. There, I think Monod was right in saying that the scientific world picture has been built by abjuring final causes. I have little sympathy with those of his critics who dislike mechanistic theories in science because they lack moral uplift. But there is second issue, concerning the strategy of scientific research; there, I think Monod's critics have a case. I do not think it will prove possible to explain biology in molecular terms in quite the way Monod hopes. For example, he writes "personally I am convinced that in the end only the shape-recognising and stereospecific binding properties of proteins will provide the key to these phenomena" (that is of development). My own guess is that it will no more be possible to understand the shapes of embryos in terms of the properties of proteins than it is possible to understand the shapes of the waves generated in Jabotinski's reaction in terms of the shapes of the constituent molecules. Of course, theories of development will be dependent on and consistent with molecular biology but they will not be discovered by thinking only at the molecular level.

This guess may be wrong. But then, I wish I was as sure of anything as Monod is of everything. How a man can write "This central concept of modern biology is no longer one among other possible or even conceivable hypothesis, the only one compatible with observed and tested fact. And nothing warrants the supposition (or the hope) that conceptions about this should, or ever could be revised", and claim to be a Popperian, I do not know.

John Maynard Smith

### Critical look at the LMFBR

The Liquid Metal Fast Breeder Reactor. By Thomas B. Cochran. Pp. xiv+271. (Johns Hopkins University: Baltimore and London, 1974.) \$6.95.

I CANNOT do better than quote from the preface:

"In this monograph Thomas Cochran takes a critical look at the economic and environmental arguments which have been made in favor of an early introduction of the liquid metal fast breeder reactor (LMFBR) as a central component of the United States electrical energy system."

Taking a number of published United States (US) reports, particularly the cost/benefit analyses put out by the US Atomic Energy Commission in 1970 and 1972, he considers in reasonable detail the choice of discount rate, the assessment of generating costs, the validity of currently assumed perform-

ance parameters, fuel cycle costs, and the arguments relating to the supply and demand of uranium.

Cochran may be right in parts of his criticism, but recent history has shown the need for frequent revision both of the ground rules in policy analyses and of the assumptions that form the background to them. In keeping with his pessimistic view of the LMFBR he suggests the continued use of thermal reactors and the stock-piling of the depleted uranium for future use—maybe not with LMFBRs. He advocates further investigation of alternative energy sources, without offering much hope of better success in any other direction.

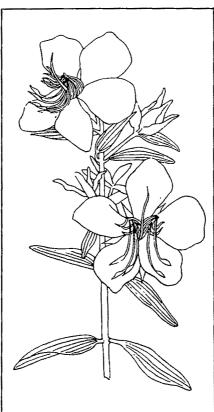

That part of his submission which challenges the proposal to build many fast reactors between 1986 and 2000 is perhaps less important in terms of today's decision than his critical comparison between the LMFBR and the light-water reactor. Neither in the US nor the UK do we yet know what new information and experience will be available by 1986, and the present need is to ensure a capability of energy production in the latter part of this century. To that end the UK, France, Germany, Italy, Japan and the Soviet Union are actively developing the LMFBR—a system with which Europe has considerably more experience than the United States.

Many of the problems Cochran raises are common to any programme of nuclear power, such as the long-term storage of radioactive waste and the processing and transport of fuel. These become more acute with the rate of increase of the total power programme and are little affected by the choice of systems.

Mr Cochran has made an excellent attempt to analyse the safety of the fast reactor in simple terms. I wish to comment only on a few exceptions: for example, the difference in neutron lifetime is barely relevant to most accident conditions as the rate of change of temperature is dictated by the doppler coefficient, that is, controlled by the thermal inertia of the fuel. A prompt, critical situation cannot be controlled by mechanical systems, neither in thermal nor in fast reactors. The importance of the sodium void coefficient arises only if coolant is ejected from a substantial number of fuel channels. The way in which an accident might develop will be different in different reactor systems but the end effect of the potential thermal interaction of hot fuel and coolant can he violent in water reactors as well as in the LMFBR and the available energy is not markedly different.

There is a growing recognition that there is some uncertainty and consequent risk in many industrial activities, not only in the development of nuclear power, and it is obviously important to be aware of these risks in order to minimise them. This monograph should encourage further critical reviews of the US programme and the part to be played by fast reactors in a future energy economy.

F. R. Farmer

Dissotis speciosa. From Upland Kenya Wild Flowers. By A. D. Q. Agnew. Pp. ix +827. (Oxford University Press: London, November 1974.) £7.75.

### Happy union in the feldspar family

Feldspar Minerals. Vol. 1: Crystal Structure and Physical Properties. Pp. xx+627. Vol. 2: Chemical and Textural Properties. Pp. xi+690. By J. V. Smith. (Springer-Verlag: Berlin and New York, 1974.) Vol. 1: DM98.30; \$40.10. Vol. 2: DM103.50; \$42.30.

THESE splendid volumes on the most abundant, ubiquitous and internally complex minerals in the Earth's crust set a new standard for advanced mineralogical texts. They are extraordinarily comprehensive and the reader must feel a sense of wonder at the author's capacity to organise so vast a body of literature into a coherent and remarkably readable whole. The hundreds of references are very up to date (1973) and much use is made of preprints and theses. The author's aim is avowedly pedagogic, to use the feld-

spars to show how physical and chemical principles can be combined with geological observations to contribute to our understanding of mineral genesis. The books therefore contain several crisp but useful sections outlining most of the many physical and analytical techniques applicable to crystalline materials in general, with many references to basic papers which develop physicochemical principles. At the other extreme, volume 2 covers at length a multitude of petrological observations on feldspar twinning and integrowths. In their marriage of crystallographic sophistication with grass-roots geological observation (a union sadly missing in much feldspar research) the books set an example applicable across the whole mineralogical field.

The volumes are so comprehensive that feldspar specialists are likely to find their own field dealt with at length, with a most valuable review of all the relevant literature; for more general readers certain sections stand out. In volume 1 the structural architecture of the feldspars is developed in great detail, beginning with discussion of models of bonding. The unsolved intricacies of the one or two-step ordering problem in K-feldspars are discussed and later related to the difficulties of classification of the K-feldspars. These sections as nomenclature are required reading for petrographers, who will also welcome the compilation of X ray and optical determinative techniques. Electron-optical methods will also find increasing use as a petrographer's tool and photographs of many fascinating (and sometimes enigmatic) textures are reproduced clearly.

Volume 2 begins with an outline of analytical techniques followed by a lengthy description of chemical substitution. Mechanisms of growth, development of chemical zoning, morphology and all the many feldspar twins are described, with structural explanations and a widely applicable discussion of twinning mechanisms. Similarly, intergrowths of feldspar with feldspar and with a host of other minerals are explained in terms of mechanisms of exsolution and replacement. Volume 3, dealing with phase equilibria and petrogenesis (promised for 1976) must be awaited eagerly by all mineralogists and petrologists. These lavishly produced, totally comprehensive volumes bring out, through the author's obvious enthusiasm, all the fascination there is in using modern techniques to explain mineral variation and it is to be hoped that they will be treated not just as invaluable works of reference, but also as a guide to all that is possible in modern mineralogical work.

#### APPOINTMENTS VACANT

#### "METALS ABSTRACTS"

The international abstracting service for metallurgy offers permanent positions as SENIOR EDITORIAL ASSISTANTS. The work consists of editing and checking abstracts for publication. A science degree, preferably in metallurgy, physics, or chemistry, is necessary and a working knowledge of a foreign language would be an advantage.

Applications, stating age, education, qualifications, and experience, to Dr T. Graff, Metals Abstracts, The Metals Society, I Carlton House Terrace, London SWIY 5DB.

#### DEAN OF THE FACULTY OF SCIENCE

The newly-established Faculty of Science of the University of Regina requires a dean to consolidate programs and provide leadership. The University is seeking a person with an established reputation in research and with successful administrative experience. The Faculty contains six departments and 70 permanent faculty members. The Faculty offers three and four year undergraduate programs and graduate programs to the Ph.D. level.

Please apply to Mr. D. T. Lowery, University Secretary, University of Regina, Regina, Saskat-chewan, Canada, S4S 0A2. (2195)

#### DEPARTMENT OF PHYSICS UNIVERSITY OF ALBERTA ELECTRONMICROSCOPIST

Applications are invited for an Assistant Professor in the area of Electronmicroscopist. Exceptional candidates in other areas of condensed state physics will be considered. The condensed state group at the University of Alberta consists of eight members in a Physics Department of forty-two faculty members. faculty members.

The effective date of appointment is April 1, 175. The closing date for applications is February 1, 1975.

Send vitae, list of publications, and names of three referees to: Dr J. T. Sample Chairman

Department of Physics
University of Alberta
Edmonton, Alberta, T6G 2E1 (X1911)

#### UNIVERSITY OF ALBERTA Edmonton, Alberta, Canada ASSISTANT PROFESSOR PHYSIOLOGY

Salary negotiable, M.D. and/or Ph.D. Strong research interests or interest and teaching ability essential. Apply with curriculum vitae and names of three referees by January 24, 1975.

Applications to: Dr M. Schachter, Professor and Chairman, Dept. of Physiology, University of Alberta, Edmonton, Alberta, Canada. (2237)

### Laboratory Manager for Evans Biologicals Limited from £2,700

We require a manager to take charge of a laboratory which responsible for the preparation and growth testing of tissue cultur for production, research and test programmes. In addition, at a lat stage, responsibility for the control of the safety testing of vir vaccines will be involved.

Candidates, who must have relevant experience as a laborato manager, should have a degree or H.N.C. in a biological subject or ha an I.M.L.T. qualification.

We are one of the country's leading manufacturers of human a veterinary vaccines and are located at Speke near Liverpool, with easy travelling distance of pleasant residential areas in Cheshire, t Wirral and on the Lancashire coast.

Starting salary will be from £2,700 according to qualifications a experience. In addition the conditions of employment include 4 wee which we are a member and assistance with re-location expen where appropriate.

Please write with brief career details, quoting reference U.53, t

Dr M. C. Cook, Management Staff Adviser, Evans Medical Limited, Speke, Liverpool L24 9JD.

[] Application forms (for return by 17 January 1975), from Civ Commission, Alencon Link, Basingstoke, Hants RG21 1]B, Basingstoke 29222 ext. 500 (or, for 24 hour answering service 01-839 1992).

### SIMON FRASER UNIVERSITY DEPARTMENT OF GEOGRAPHY

Burnaby, B.C., Canada

Position: Chairman, Department of Geography, Senior academic preferred, active scholar with strong interest in teaching, Canadian experience desirable. To Chair department for a renewable term of 2 to 5 years.

Rank and salary negotiable, Appointment on or before September 1, 1975.

Applications, with curriculum vitae, to be sent to:

Dean W. A. S. Smith Faculty of Arts Simon Fraser University Burnaby, B.C. V5A 1S6 Canada.

Deadline for applications is January 15, 1975 but applicants are encouraged to apply as early as possible.

#### UNIVERSITY OF WESTERN ONTARIO DEPARTMENT OF ZOOLOGY ASSISTANT PROFESSORS

Applications are invited for the positions of: VERTEBRATE POPULATION BIOLOGIST familiar with quantitative analysis and specialising in population dynamics, ecological genetics, behaviour or reproduction; and ECOLOGIST specialising in aquatic populations or ecosystems. Both positions are three year probationary appointments starting in July or September 1975. Starting salary of at least \$13,025. Applicants should have demonstrated ability to develop active independent research programmes and be familiar with modern teaching methods.

Send curriculum vitae (include telephone number) and three letters of reference by February 1, 1975

Or M. Locke, Chairman, Department of Zoology, University of Western Ontario, London, Canada N6A 3K7.

#### UNIVERSITY OF BRISTOL ION THRUSTERS FOR SPACE PROPULSION

Applications are invited for the post of Research Assistant at postdoctoral or equivalent level in the Department of Aeronautical Engineering, to start a new research project, sponsored by the S.R.C., on the use of xenon for an ion thruster.

The work will involve the design and construction of a suitable test facility, and the investigation of the performance of an ion thruster using xenon gas as a propellant. The thruster will be provided by the Space Department of R.A.E. Farnborough.

Applicants should have a good degree in Physics or Engineering; preference will be given to applicants with appropriate research or industrial experience, particularly in plasma physics. The starting salary will be up to £2,412 per annum, plus Threshold Agreement supplements. The appointment would be expected to continue for three years.

Applications, giving details of qualifications and potgraduate experience and the names of two referees, should be sent to Professor L. F. Crabtree, Queen's Building, Bristol BS8 1TR. (2252)

### OXFORD UNIVERSITY PHYSICAL CHEMISTRY LABORATORY AND ST JOHN'S COLLEGE

AND ST JOHN'S COLLEGE

Applications are invited for a joint appointment to a Departmental Demonstratorship in Physical Chemistry and a Fellowship by Special Election at St John's College. The appointment will be for a limited term, which will not exceed five years, and at a joint salary on the scale of a University Lecturer and Official Fellow. It is hoped to make an appointment starting in either April or October 1975. For further particulars of the Demonstratorship please write before February 1, 1975, to Professor J. S. Rowlinson, Physical Chemistry Laboratory, South Parks Road. Oxford OX1 3QZ. England, who will also forward particulars of the College Fellowship. (2253)

#### THE UNIVERSITY OF LANCASTER

DEPARTMENT OF ENVIRONMENTAL SCIENCES

### LECTURESHIP IN GEOPHYSICS

Applications are invited for the above post tenable from October 1, 1975. The successful candidate will be required to teach undergraduate courses in geophysics and to assist with teaching in related subjects.

The main departmental research interests in solid earth geophysics at present are concerned with Crustal and Upper Manute Studies using deep magnetic soundings, with facilities for complementary gravity and seismic studies and for magnetic survey. Preference will be given to a candidate with research interests in deep magnetic sounding or related fields.

Further particulars may be obtained (quoting reference L.857/C) from the Establishment Officer. University House, Lancaster LA1 4YW, to whom applications (five copies), naming three referees, should be sent not later than February 28, 1975. (2248)

#### CELLULAR IMMUNOLOGIST

Post- or pre-doctoral, with experience of culture methods, to join a team investigating lymphocyte and phagocyte function in relation to immunodeficiency and grafting, tumour immunotherapy and rheumatoid diseases.

Salary, Whiteley A scales, up to £3,144 p.a.
Applications by January 6 1975 to Professor
J. R. Hobbs, Westminster Medical School, 17
Page Street, SW1P 2AR. (2255)

Applications are invited for a

## lectureship in Astrophysics

at the Astronomical Institute.

Duties will include research and teaching activities (graduate and undergraduate level).

Applicants should have a good knowledge of astrophysical observing techniques - especially stellar spectroscopical - and a thorough insight of the physical processes bearing on stellar evolution. The present research interests are in hydrodynamical processes, nucleosynthesis, and high energy electromagnetic processes (X-ray and ultraviolet radiation of stars and astrophysical plasma's). Salary in accordance with background and experience.

Send curriculum vitae, names of at least two referees, and present research interests, quoting nr. 185 AX to: prof. dr. E. P. J. van den Heuvel, Astronomical Institute, Roetersstraat 15, Amsterdam, The Netherlands.

Applications should be sent not later than January 15, 1975.

Universiteit van Amsterdam

#### OXFORD POLYTECHNIC

Applications are invited for the post of

#### SENIOR LECTURER/ LECTURER II IN GEOLOGY

to take charge of teaching, and initiate research in Geochemistry.

Further details and application

Deputy Director, Oxford Polytechnic, Oxford OX3 0BP. (2243)

#### M.R.C. CLINICAL RESEA'RCH CENTRE

(Northwick Park Hospital) Watford Road, Harrow, Middlesex HA1 3UJ TUMOUR IMMUNOLOGY

#### JUNIOR TECHNICAL OFFICER

to work in the Division of Surgical Sciences in research in cellular immunology, with particular emphasis on tumour immunology. This involves some small animal work and a wide variety of in vitro techniques. Salary within the range £1,875 to £2,718 plus £228 threshold. Candidates with degree, H.N.C. or equivalent should apply to Mrs J. Tucker-Bull for application forms.

Please quote ref. 128/2/4302.

### Young Morphologist

YOUNG MORPHOLOGIST required immediately for scientific staff of research unit working in development neurobiology field. Unit now at Carshalton, but a move to WC1 area of London is

Applicants should have at least 3 years' postgraduate experience. The studies will be concerned with investigations on the developing Central Nervous System with light and electron microscopy, and will also involve co-operative studies with biochemists and neuroendocrinologists working in the Unit.

Appointment will be for 3 years; salary in the range £2,019 to £3,636; F.S.S.U. Superannuation.

Apply to Dr R. Balázs, Neuropsychiatry Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey. (Tel. 01-643 8000).

#### UNIVERSITY OF QUEENSLAND Australia

#### SENIOR LECTURER/LECTURER IN BIOMETEOROLOGY

(Environmental Biophysics)

The Department of Botany invites applications from biometeorologists to undertake teaching and research in the field of energy dynamics of plant communities in co-operation with plant ecologists and physiologists. An understanding of hydrology and systems analysis would be desirable. January 3, 1975.

#### SENIOR TUTOR IN BIOCHEMISTRY

Applicants should have as minimum qualifica-tions an honours science degree, but preferably should have a higher degree. Applicants should indicate their research interests. They will be re-quired to do some lecturing and to direct some laboratory classes. January 10, 1975.

GENERAL CONDITIONS: Salary (under review)— Senior Lecturer \$A12,643 to \$A14,724; Lecturer \$A9,002 to \$A12,352; Senior Tutor \$A7,545 to \$A9,002 per annum.

OTHE BENEFITS: Lecturer and above—Super-annuation similar to F.S.S.U., housing assistance, reaveiling and removal expenses.

Senior Tutor—Superannuation similar to F.S.S.U., housing assistance, travelling and removal expenses.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WCIH 0PF. (2235)

### **Physiological** Chemistry

The special Projects Group in the Development Division of Nicholas, based at Slough, undertakes fundamental studies of a typical chemical nature in a number of fields of pharmaceutical interest.

We are currently seeking a person with a knowledge of physiology, preferably with M.Sc. or equivalent post graduate experience, to strengthen the group's expertise in the subject.

The position will provide the opportunity to work in a wide range of subjects with a high degree of autonomy. The successful applicant should be prepared to adopt an interdisciplinary approach to problems, to take an active part in problem definition, and should preferably have some knowledge of discussion and membrane process.

A competitive salary will be paid and the company offers above average conditions of employment. Please write or telephone for an application form to: Ron Klerks, Personnel Officer, Nicholas Laboratories Limited, 225 Bath Road, Slough, Berks. Tel: Slough 23971.

Guy's Hospital Medical School

#### GRADUATE RESEARCH ASSISTANT

required in the Department of Medicine to work for three years on the study of purine metabolism in uraemia. The post is suitable for a biochemist or enzymologist, preferably with a knowledge of chromatographic and electrophoretic techniques, automated analyses and the use of isotopes. Opportunity to register for higher degree.

Salary up to £2,022 per annum according experience, with Superannuation and Threshold Payments.

Apply in writing, with curriculum vitae, the Secretary, Guy's Hospital Medical chool, London Bridge, SEI 9RT, quoting ef. P.M. (2270)

#### UNIVERSITY OF MELBOURNE LECTURESHIP (LIMITED TENURE) IN THE DEPARTMENT OF ZOOLOGY

Applications are sought from Zoologists with interests and experience in the ecology of populations and communities.

Duties will include general undergraduate teaching in ecology at all levels, the major responsibility for a unit course in ecology in the second year, establishment of a research programme and the supervision of research students.

The appointee will be expected to take up duties as soon as possible after June 1, 1975.

Salary: \$A9,002 to \$12,352 per annum

Further information including details of application procedure and conditions of appointment is available from the Registrar, University of Melbourne, Parkville, Victoria 3052, Australia, of from the Association of Commonweakh Universities (Appts), 36 Gordon Square, London WCIH 0PF.

Applications close on January 31, 1975.

#### MEDICAL RESEARCH COUNCIL

TOXICOLOGY UNIT

#### TECHNICIAN/ JUNIOR TECHNICIAN

required in electron microscopy laboratory. Applicants for the Technician category must possess AIMLT or HNC or equivalent and preferably appropriate experience. Alternatively, applicants for the Junior Technician category may be considered and they should possess ONC or equivalent. Salary according to age, qualifications and experience. Apply in writing only to The Director, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey." (2267)

#### UNIVERSITÄT HOHENHEIM (LH)

A Chair of Plant Nutrition (AH 4) will be vacant as per 1.4.1976.

The new colleague will have to teach Plant Nutrition for students of General Agriculture, Agricultural Biology as we'll as Biology and to cooperate with two other professors in the department.

Concerning work he is expected to deal with physiological and ecological aspects of plant nutrition with special regard to yield and quality. Participation in the research programme "Ernährungsphysiologische Qualität landwirtschaftlicher Produkte" is desired.

Applications with the usual documents should arrive not later than 1.4.75 at the Dekan des Fachbereichs V der Universität Hohenheim (LH) 7 Stuttgart 70 (Hohenheim) Postfach 106

(2236)

#### UNIVERSITY OF SYDNEY CHAIR OF VETERINARY SURGERY

Applications are invited for the Chair of Veterinary Surgery which will become vacant on the resignation of Professor L. H. Larsen at the end of 1974.

The salary will be at the rate of \$A19,614 per

A statement of Conditions of Appointment and Information for Candidates may be obtained either from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Acting Registrar, University of Sydney, New South Wales 2006, Australia

ustralia.

Applications close on January 24, 1975.

(2238)

#### UNIVERSITY OF BENIN-NIGERIA

Applications are invited for the following posts in the DEPARTMENT OF CHEMISTRY:—

SENIOR LECTURER/

LECTURER IN THEORETICAL CHEMISTRY SENIOR LECTURER/ LECTURER IN INDUSTRIAL CHEMISTRY

SENIOR LECTURER/ LECTURER IN MATERIALS SCIENCE

(Polymer Chemistry, Metallurgy or Ceramics). Salary scales: Senior Lecturer N5,030 to N5,750. Lecturer N2,760 to N4,830 p.a. (£1 sterling=N1.44). The British Government may supplement salaries in range £750 to £1,150 p.a. (sterling) for married appointees or £250 to £50 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holidav visit passages. Current rates of supplementation are under review and results will be announced shortly. Revised rates will be effective from April 1, 1974. F.S.S.U. Various allowances. Application forms are available from the Registrar, University of Benin. PMB 1154, Ekwena Road, Benin City, Nigeria. Completed applications should be returned by air mail not later than January 17, 1975. Applicants esident in the \*UK should also send a copy to Inter-University Council, 90/91 Tottenham Court Road, London WIP ODT. Further particulars are available from either address. (2264) (Polymer Chemistry, Metallurgy or Ceramics).

### **Assistant** Librarian

with natural sciences qualification Ulverston, Cumbria.

An Assistant Librarian is required for our Ulverston factory, which manufactures antibiotics, enzymes and vitamins. The person appointed will join a small group giving a comprehensive library and information service to all departments of the factory.

The person appointed will be required to assist with the scanning of incoming literature, to undertake literature searches and compile bibliographies, answer enquiries, and assist with classifying additions to the library.

Candidates should have a professional qualification in librarianship or information science, with experience of working in a technical library, and should be graduates in one of the natural sciences.

The salary will be according to qualifications and experience. The company offers good conditions of service including bonus, pension and sick pay schemes.

Ulverston is a pleasant market town situated on the southern fringe of the Lake District National Park. Assistance with relocation expenses will be given where appropriate.

Please apply in writing quoting ref. U.691, to: The Personnel Officer (JE), Glaxo Laboratories Limited. North Lonsdale Road, Ulverston, Cumbria LA12 9DR. (2256)

### UNIVERSITY OF BIRMINGHAM THE DENTAL SCHOOL

A research team working on the biological evaluation of dental materials now needs a graduate in Biology or Zoology to undertake experimental implantation of materials under test and the assessment of their detailed effects upon dental and other tissues. The post, at the grade of RESEARCH ASSOCIATE or SENIOR RESEARCH ASSOCIATE is on a part-time basis, hours subject to negotiation, and would suit a married graduate with family responsibilities. No dental experience is required and the appointee will be given the necessary training on special dental aspects.

Salary pro rata on scale £1,758 to £3,285 (to £4,896 if candidate is exceptionally well qualified).

Further particulars from Assistant Registrar, Dental School, St. Chad's Queensway, Birmingham, B4 6NN, to whom applications including curriculum vitae and the names of three referees should be submitted within three weeks of the appearance of this advertisement. (2260)

#### UNIVERSITY OF OXFORD DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a postdoctoral research assistantship in metabolic biochemistry. The research will involve an investigation into the effects of ageing and certain drugs on some metabolic processes in the brain. The appointment is for two years at a starting date not later than May 1. 1975. The salary will be in the range £2,010 to £2,247 plus threshold payment and the person appointed will be eligible for membership of F.S.S.U. (or its equivalent).

Applications, with the names and addresses of two referees, should be sent to Dr E. A. Newsholme, Department of Biochemistry, South Parks Road, Oxford 0X1 3QU. The closing date for applications is February 14, 1975. (2271)

#### THE UNIVERSITY OF MANCHESTER DEPARTMENT OF MEDICAL BIOPHYSICS

Applications are invited for the post of Electron Microscopy Technician, Grade 5, in the Biophysics Laboratory of the Department. The person appointed will be responsible for the operation and day-to-day maintenance of three electron microscopes. He should have considerable experience and be acquainted with a wide range of specimen preparation techniques and photographic procedures and should be capable of assisting academic staff with research projects.

Applicants should have an H.N.C. or equivalent qualification. Salary scale £2,439 to £2,895 p.a. The post is superannuable.

Applications should be sent as soon as possible to Dr J. A. Chapman. Department of Medical Biophysics. Stopford Building, Manchester University, Oxford Road, Manchester M13 9PT.

(2285)

#### MEDICAL RESEARCH COUNCIL

**NEUROPSYCHIATRY UNIT** 

#### MORPHOLOGY ASSISTANT

required in Medical Research Council Neuropsychiatry Unit, with emphasis on electron microscopy. Experience in studies on the nervous system an advantage. Salary according to age and qualifications in range £1,860 to £2,835 plus £126 London Weighting.

Apply to Dr R. Balázs, Medical Research Council, Neuropsychiatry Unit, Woodmansterne Road, Carshalton, Surrey. (2266)

## Senior Bacteriologist from £4000

Ewans Biologicals Limited is one of the country's leading manufacturers of human and veterinary vaccines. Its modern premises are situated in Speke on the outskirts of Liverpool within commuter distance of Cheshire, The Wirral and Lancashire coast.

We now wish to appoint a Senior Bacteriologist to take charge of our pertussis vaccine programme when the present incumbent retires early in 1975.

We require someone who will probably have a post graduate qualification and considerable practical experience, with pertussis organisms and vaccines, so that we can maintain our eminence in this field.

Applicants should be able to justify a salary of at least £4,000. Salary will be negotiable above this according to qualifications and experience. Conditions of employment include a contributory pension scheme, the Glaxo Group profit based on bonus and assistance with relocation expenses where appropriate.

Please write, with brief career details, quoting reference U.54, to:

Dr M. C. Cook, Management Staff Adviser, Evans Medical Limited, Speke, Liverpool L24 9JD.

(2269)

SHEFFIELD AREA HEALTH AUTHORITY (TEACHING)
SHEFFIELD CENTRAL DISTRICT (TEACHING)

DEPARTMENT OF IMMUNOLOGY

### NON-MEDICAL SCIENTIFIC OFFICER

(Basic Grade)

required for a period of one year (in the first instance) for research into fetoprotein separation and quantitation.

Applicants should possess a 1st or 2nd Class Honours Degree in an appropriate subject. Experience in protein separation techniques and radioimmunoassay would be an advantage. For further details and arrangements to view the Laboratory, contact Dr A. M. Ward, Department of Immunology, Hallamshire Hospital, Sheffield. Telephone: (0742) 26484. Ext. 229.

Whitley Council Terms and Conditions of Service apply.

Salary Scale: £2,046 to £2,562 p.a. plus Threshold Agreement payments.

Applications in writing, stating age, qualifications, experience and the names and addresses of two referees to the District Administrator, Sheffield Area Health Authority (Teaching), Sheffield Central District (T), 10 Beech Hill Road, Sheffield S10 2RZ. (2276)

#### **PHARMACOLOGIST**

experienced, with veterinary or medical qualifications preferred, required for pharmacological research and toxicological studies of compounds of potential therapeutic importance. Also vacancies for New Graduates as trainees. Excellent opportunities for advancement in modern, well-equipped laboratory, Pension and Assurance Scheme. Application forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB.

#### The Hannah Research Institute INFORMATION OFFICER/ LIBRARIAN

Applications are requested for the above post. The appointment will be within the Higher Scientific Officer grade (£2,461 to £3,371, plus threshold agreement). The post is pensionable. Applicants should possess a diploma or degree in science or agriculture and have a qualification in, or experience of, some aspect of information science. Applications, giving a full curriculum vitae and the names of two referees, should be sent to the Secretary, The Hannah Research Institute, Ayr. KA6 5HL, from whom further particulars may be obtained, by January 16, 1975. (2272)

#### FLATFORD MILL FIELD CENTRE

GRADUATES (females) wanted who would be interested in the post of Temporary Help (cooking) at Flatford Mill Field Centre whilst searching for permanent appointments. Could attend interviews and leave at short notice if necessary. Please write to The Warden, Flatford Mill Field Centre, East Bergholt, nr. Colchester, Essex or telephone (reverse charges) East Bergholt (020-629) 283. (2274)

#### MONASH UNIVERSITY Melbourne, Australia DEPARTMENT OF PHYSIOLOGY (INCLUDING PHARMACOLOGY) LECTURER/SENIOR TUTOR

The Department conducts courses for B.Sc. (Hons) and M.B., B.S. degrees and accepts graduate students for M.Sc. and Ph.D. degrees. Research interests include: brain ultra structure, neurophysiology, biophysics and pharmacology of central and peripheral synapses, muscle biophysics, circulatory physiology and pharmacology, renal and endocrine physiology. Applicants should be medically qualified or hold a Ph.D. in Physiology.

Salary scales (currently under review): Lecture.

Salary scales (currently under review): Lecturer (Medically qualified) \$A11,502 to \$A14,852. Lecturer \$A9,002 to \$A12,352 per annum, Senior Tutor \$A7,545 to \$A9,002 per annum, with superannuation based on an endowment assurance scheme, the employee and employer contributing 5% and 10% respectively.

respectively.

Benefits: Travelling expenses for appointee and family; removal allowance, repatriation after three years' appointment if desired: temporary housing for an initial period. For Lecturers only, study leave entitlement accumulates at the rate of one month's leave for each six months' service up to six years, with provision for financial assistance.

Further general information and details of appli-

Further general information and details of application procedures are available from the Academic Registrar, Monash University, Wellington Road, Clayton 3168, Victoria, Australia, or the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH OPF, Enquiries about the Department to the Chairman, Professor R. Porter, in the University.

Closing date January 31, 1975.

The University reserves the right to make no appointment or to appoint by invitation.

#### FELLOWSHIPS AND STUDENTSHIPS

#### QUEEN ELIZABETH COLLEGE (University of London) DEPARTMENT OF CHEMISTRY DECCA RADAR POSTDOCTORAL RESEARCH FELLOWSHIP IN RADIOFREQUENCY SPECTROSCOPY

Applications are invited for a postdoctoral re-search fellowship in radiofrequency spectroscopy of the solid state, with particular reference to nuclear quadruple resonance.

Candidates should have a good research record in Physics, Chemistry or Chemical Physics and experience of and interest in instrumentation and computing would be an additional qualification.

This postdoctoral fellowship, tenable for two years, is supported by Decca Radar, Initial salary not less than £2,854 plus F.S.S.U.

Applications with curriculum vitae and the names of two referees should be sent to Professor J. A. S. Smith, Department of Chemistry. (N) Queen Elizabeth College, Campden Hill, London W8 7AH as soon as possible. (2244)

#### UNIVERSITY COLLEGE DUBLIN POSTDOCTORAL FELLOWSHIP IN PHYSICAL ORGANIC CHEMISTRY

Applications are invited for a Postdoctoral Fellowship to investigate intramolecular and bifunctional catalysis in R-eliminations with emphasis on analogies with biological reactions. The appointment, which is supported by the National Science Council of Ireland will commence on February 1, 1975 or as soon as possible thereafter. It will be renewable annually and in the normal way will extend to September 31, 1977.

Salary will commence at not less than £2,200

Applications should be sent to:
Dr R. A. More O'Ferrall
Department of Chemistry
University College Belfield Dublin 4, Ireland.

#### UNIVERSITY OF WATERLOO Waterloo, Ontaria, Canada AQUEOUS GEOCHEMISTRY-ISOTOPE GEOLOGY

Applications are invited for a postdoctoral fellowship in aqueous geochemistry-isotope geology. The successful applicant will have a strong background in low temperature geochemistry and possibly some experience in stable isotope and 14C research. The position is open immediately and the initial appointment is for one year but an extension to second year is possible. Salary according to N.R.C. regulations. Send résumé to:

Dr R. N. Farvolden, Chairman,
Department of Earth Sciences,
University of Waterloo,
Waterloo, Ontario, Canada,
N2L 3G1. (2249)

#### UNIVERSITY OF BIRMINGHAM DEPARTMENTS OF ANATOMY/ **PATHOLOGY** MEAD BEQUEST RESEARCH FELLOW

Applications are invited for the post of RE-SEARCH FELLOW to work under the joint supervision of Dr Martin Berry (Anatomy) and Professor W. Thomas Smith (Neuropathology) on an experimental study of regeneration in the central nervous system. This is a joint appointment for 3 years between the Department of Anatomy and Pathology and the extensive research facilities of both Departments will be available. Medical or non-medical graduates are invited to apply; previous experience of electronmicroscopy and/or amunofluorescent rechniques would be an advantage, though is not essential. The Fellowshin may be discussed with Professor W. T. Smith (021-472 1301 ext 3554). Department of Pathology, who will arrange for visits to the School.

Salary within the range of £2,118 to £2,931, according to age, qualifications and experience. Applications to Assistant Registrar, Faculty of Medicine, University of Birmingham, Birmingham B15 2TJ.

Closing date January 31, 1975. (2263)

Closing date January 31, 1975

(2263)

#### UNIVERSITY OF LIVERPOOL DEPARTMENT OF MEDICINE POSTGRADUATE RESEARCH STUDENTSHIPS

Applications are invited for Medical Research Council Studentships available in September, 1975.

Training is offered in a wide range of research activities principally in the fields of Immunology, Genetics, Drug Metabolism and Oncology, as related to medical problems.

Applications from students expecting to obtain II (1) Honours Science Degrees and wishing to take up Research Studentships for training in these subjects should be received not later than January 14, 1975 by the Registrar, The University. P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/349/N. (2254)

#### UNIVERSITY OF WESTERN AUSTRALIA Perth

#### POSTDOCTORAL RESEARCH FELLOWSHIP IN MATHEMATICS

FELLOWSHIP IN MATHEMATICS

Applications are invited for a Postdoctoral Research Fellowship in the Department of Mathematics. The Fellowship is being financed by the Australian Research Grants Committee and the appointee will be required to work, in collaboration with Professor J. J. Mahony, in the general area of singular perturbation theory with some emphasis on establishing the validity of formal methods. It is expected that a research monograph will result. Opportunities will be available for continued personal research in the broad general area. Experience in appropriate methods of applied functional analysis and a good knowledge of the applications of singular perturbation theory are desirable. The appointee should be able to assume duty by mid-1975.

The initial appointment will be for one year

The initial appointment will be for one year with prospects of continuation for a further term. The current salary range is \$A9,002 to \$A12,352 p.a. An allowance towards appointment expenses will be available.

Applications in duplicate stating full personal Appecations in duplicate stating rull personal particulars, qualifications and experience should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by January 18, 1975. Candidates should request three referees to write immediately to the Staffing Officer. (2283)

#### THE WELLCOME TRUST

TRAVELLING RESEARCH FELLOWSHIPS TO WESTERN AND EASTERN EUROPE 1975/76

Applications are invited from British re-search workers for the award of Wellcome-European Research Fellowships for 1975/76. These awards include the Trustees' special followships to Denmark, Germany, Hungary, Norway and Sweden.

Norway and Sweden.

The object of these fellowships is to encourage working visits to countries in Western and Eastern Europe by investigators in any branches of the natural and clinical sciences which have a bearing upon human or animal medicine. Candidates whose research is related to clinical problems will be given preference. These fellowships, which are normally for one year, are intended for graduates from the United Kingdom who already have some post-doctoral research experience. Stipends, according to age and experience, are within the range £2.120 to £4.165 per annum. A special cost of living allowance applicable to the country in which the candidate wishes to work is given where necessary. Travelling and some incidental expenses are provided in addition.

The candidate must make his own arrangements with the department in which he proposes to work, and written evidence must be submitted confirming his arrangements, Application forms may be obtained from the Assistant Director, The Wellcome Trust, No. 1 Park Square West, London, NW1 4LJ. Completed application forms must be returned by March 31, 1975. (2258)

#### UNIVERSITY OF WARWICK

Postdoctoral Research Fellowships in Biological Sciences/Molecular Sciences

Applications are invited for two postdoctoral fellowships to work with Professor D. C. Burke and Dr D. W. Hutchinson on the mechanism of interferon formation by polynucleotides. One post (financed by the M.R.C.) would be suitable for a biochemist with an interest in the use of affinity labelled compounds or in the structure and properties of eukaryotic membranes, and the other (financed by the C.R.C.) for a biochemist with an interest in virology or a virologist with a good background in biochemistry. Salary on the scale £2,118, £2,247, £2,412 (exceptionally £2,580) p.a. plus threshold payments. Further particulars and application forms may be obtained from the Academic Registrar. University of Warwick, Coventry SV4 7AL, quoting Ref. No. 19/2A/74. Closing date for receipt of applications is January 27,

#### AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

#### RESEARCH SCHOOL OF BIOLOGICAL SCIENCES PROFESSORIAL FELLOWSHIP DEPARTMENT OF GENETICS

The Department is headed by Professor W. F.R.S., and its research activities include the study of regulatory mechanisms in phage and bacteria, regulatory mechanisms and differentiation in lower eukaryotes, evolutionary studies on bacteria and vertebrates and developmental genetics of plant cell lines in tissue culture. The Department is well housed and equipped for these various fields of

It is now desired to make a senior appointment in the Department at the level of Professorial Fellow. The successful appointee, who should have demonstrated outstanding research ability, will have the opportunity of leading a small research group the Department, preferably within the field of plant cell genetics.

Closing date: February 7, 1975.

#### CENTRE FOR RESOURCE AND **ENVIRONMENTAL STUDIES** SENIOR FELLOW OR FELLOW

The primary role of the appointee will be, in collaboration with the staff and Advisory Committee of the Centre for Resource and Environmental Studies, to design a Master's course in Environmental Studies to be carried out primarily by course work, and to act as the course co-ordinator when the course is established. It is intended that students should be accepted in 1976. An opportunity will be avaisable for the successful applicant to carry out research related to current research projects of the research related to current research projects of the Centre.

There are no restrictions as to previous training and experience but the applicant should have research ability and some teaching experience. The applicant must be interested in environmental problems and in organising teaching at the graduate level.

Closing date: January 31, 1975.

Salaries (under review): The salary for a Pro-fessorial Fellow is \$A18,131 p.a. Salary on appoint-ment to the other posts will be in accordance with ment to the other posts will be in accordance with qualifications and experience within the ranges; Senior Fellow \$A14.724 to \$A16.921 p.a.; Fellow \$A10.771 to \$A14.704 p.a.; Current exchange rates are approximately \$A1:56p;\$US1.31.

Other Conditions: Tenure: Professorial Fellow to retiring age (65 years); Senior Fellow and Fellow for five years in the first instance with the possibility of extension to retiring age.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra, Superannuation is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appis), 36 Gordon Square, London WCIH 0PF for further particulars before applying.

#### UNIVERSITY OF BIRMINGHAM DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSOCIATE OR RESEARCH FELLOW

Applications are invited for the above post for research on the occurrence, effects and control of lipid peroxidation processes in mitochondrial membranes from normal and cancer cells. A preferred and experience in the biochemistry of lipids and mitochondria an advantage.

Salary scales: Research Associate £1,758 to £2,412; Research Fellow £2,118 to £2,412 both plus F.S.S.U. and threshold payments.

Applications, including names of two referees by January 31, 1975 to Assistant Registrar (RS). University of Birmingham, P.O. Box 363, Birmingham B15 2TT. Further particulars are available from Dr A. A. Horton, Department of Biochemistry, Please quote ref. BN. (2262)

#### UNIVERSITY OF BIRMINGHAM DEPARTMENT OF EXPERIMENTAL PATHOLOGY

A Research Fellow is required to join a research team under M.R.C. sponsorship presently working on carcinoembryonic antigen and cell mediated tumour immunity on patients with cancer and other diseases. Applications are invited from graduates with research qualifications and experience in related fields, Salary: £2,118 to £2,412 plus F.S.S.U.

Enquiries and applications should be made to Dr P. W. Dykes, Department of Experimental Pathology, University of Birmingham, Birmingham B15 2TJ. (AK2278)

#### THE UNIVERSITY OF ASTON IN BIRMINGHAM DEPARTMENT OF PHARMACY RESEARCH IN PHARMACEUTICAL **SCIENCES**

The Department has recently attracted substantial research funds from Industry, the Research Councils and other institutions and has particularly close links with Pharmaceutical Industry and the West Midlands Regional Health Authority. As part of a general expansion of research activities in the Department, the following vacancies are available:

#### POSTGRADUATE STUDENTSHIPS

These awards (based on S.R.C. provisions) are available in Medicinal Chemistry, Microbiology, Pharmaceutics and Pharmacology and successful applicants will register for a Higher Degree, Recent graduates in Pharmacy or any appropriate discipline, and students who anticipate graduating in 1975 are invited to visit the Department or write to the Postgraduate Tutor, Dr M. F. G. Stevens, for further information.

#### RESEARCH FELLOWSHIP IN PHARMACEUTICAL BIOLOGY (Ref. No. 009)

The successful candidate will work on resistance of Gram-negative organisms and preference will be given to candidates with experience in the biochemistry of bacterial envelopes.

The appointment will be for a period of two years and the commencing salary will be within the range £2,118 to £2,412 per annum.

Intending applicants may obtain information on the nature of the work from Professor M. R. W. Brown, Department of Pharmacy, Application forms and other details may be obtained from the Staff Officer (quoting Ref. No. 009/6), the University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET to whom applications should Birmingham B4 7ET to wnom appearance of be returned within 14 days of the appearance of (2279)

#### WANTED

Books etc., on algae, especially diatoms. M. H. Winfield, 2 Hemming Close, Totton, Southamp-(2216)

#### SOFT LASER SCANNING DENSITOMETER

New for scanning Isoelectric Focusing in tube or plate form, High 3H resolution. Also for emission plates, X-ray film, TLC and clinical electro-

phoresis. Recorder and integrator included, Mail samples for free scanning,

#### ALSO

Single Hollow Fiber Concentrator for concentrating urine, CFS and other fluids, 2 mi - 20 fold in 25 seconds, 200 ml to 1 ml in 45 minutes, Reusable, Anal. Chem. 46:477,1974.

Blomed Instruments. 6 N. Michigan, Suite 2000, Chicago, IL. 60602

ICN — Montreal • Linton Instrumentation — Harlow • Serva Technik — Heidelberg • Landre Mijnssen — Diemen • Funakoshi Pharmaceutical — Tokyo • MDA Scientific — Park Ridge, IL. (2242)

#### UNIVERSITY OF ST. ANDREWS

#### **Electron Microscope**

A 12-year-old, carefully maintained transmission electron microscope (Siemens Elmiskop I, modified to give performance comparable with IA) is for sale. Resolution at least 40 Å. Price £2,000; lower offers considered. Installation and transport costs to be borne by purchaser. Enquiries to Dr J. B. Tucker, Department of Zoology, The University, St Andrews, Fife KY16 9TS. (2281)

#### **GRANTS & SCHOLARSHIPS**

#### THE NATIONAL KIDNEY RESEARCH **FUND**

invites applications for grants for renal research. at units within the United Kingdom. Application forms are available from The Secretary, 184B Station Road, Harrow, Middlesex HA! 2RH (01-836 4469). (2268)

#### AUSTRALIAN NATIONAL UNIVERSITY

## SCHOLARSHIPS FOR Ph.D. DEGREE COURSES

Persons, who hold, or expect to hold, a Bachelor degree with at least upper second-class honours or equivalent from a recognised university and who have a capacity for research, are invited to apply for Australian National University Ph.D. Scholarships. These are tenable in the Institute of Advanced Studies, in the School of General Studies or in the Computer Centre and are offered in the fields of study listed below:

Natural Sciences: Analytical Chemistry Biochemistry Biogeography

Botany Chemistry

Developmental Biology Environmental Biology Experimental Pathology

Forestry Genetics

Geomorphology

Human Biology (Human Genetics, Urban Biology)

Immunology
Inorganic Chemistry
Medical Chemistry
Microanalytical Chemistry

Microbiology
Molecular Biology
Neurobiology
Neurochemistry
Neuropharmacology
Organic Chemistry
Physical Biochemistry
Physical Organic Chemistry
Physical Organic Chemistry
Physical and Theoretical Chemistry

Physiology (Visual Neurophysiology, Muscle Biophysics)

Population Biology Taxonomy X-ray Crystallography

Zoology

Medical Sciences: Clinical Science Physical Sciences:

Applied Mathematics

Astronomy
Colloid Science
Computer Science
Diffusion Research
Electron and Ion Physics
Engineering Physics

Laser Physics

Mathematical Biology

Nuclear Physics Plasma Physics Pure Mathematics Solid State Physics Statistical Mechanics

Statistics Theoretical Physics Vision Research Earth Sciences:

Experimental Petrology and Geochemistry

Geochemistry

Geochronology and Radiogenic Isotopes

Geology Geophysics

Major and Trace Element Geochemistry

Mineral Physics

Palaeomagnetism and Geochemistry

Rock Mechanics Seismology

Scholarship Benefits: The basic living allowance payable is \$A3760 per annum tax-free, but is \$A5420 for those with appropriate medical qualifications. In addition, those with dependants may be paid allowances for their dependants. All allowances are reviewed at regular intervals. Return economy-standard air fares and reimbursement of some removal expenses are normally provided. Although the University cannot undertake to provide accommodation, it will assist where possible in this regard and does have a limited number of houses for married scholars.

Tenure: Subject to agreement with the department in which a scholarship is offered, a scholarship may be taken up at any time during the year. Subject to satisfactory progress, a Ph.D. Scholarship is tenable for the whole period of a course of study and research for the degree of Doctor of Philosophy, usually three years.

Applications: Application forms and further particulars are available from the Academic Registrar, The Australian National University, P.O. Box 4, Canberra ACT 2600, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF.

There is no set closing date. Applicants from outside Australia are advised to apply, stating field of interest, at least six months before they would expect to be able to take up a Scholarship, if offered.

Completed applications from overseas should be sent direct to the University and not to the nearest Australian Embassy, High Commission or Consulate. Successful applicants will be notified of any requirements which they will have to satisfy for entry into Australia as private students. (2239)

#### LECTURES AND COURSES

### UNIVERSITY OF ABERDEEN DEPARTMENT OF MEDICAL PHYSICS

This Department is an integral part of a major teaching hospital and offers: An M.Sc. DEGREE COURSE. This 12 month postgraduate course covers both fundamental studies and practical work in a wide range of the applications of Physics in Medicine. It is aimed at training for a career in medical or hospital physics. N.H.S. Physicists and engineers may take the course by block release in two diets of four months with additional work in their own hospital.

Research training leading to Ph.D. DEGREES is also available in the following subjects:

- (a) Radioisotope imaging.
- (b) Ultrasonic imaging and hazards.
- (c) Electron and nuclear spin resonance in biological materials.
- (d) Electronics and mechanics applied to medicine.
  (e) Radiation and particle dosimetry.
- S.R.C and M.R.C. grants are available to candidates with good first degrees in Physics or related disciplines.

Further particulars from: Professor J. R. Mallard, Ph.D. D.Sc., F.Inst.P., C.Eng., M.I.E.E., F.R.S.E., Department of Medical Physics, The University, Aberdeen, (2273)

#### **MISCELLANEOUS**

#### SABBATICAL?

Rent/exchange homes/appts., world-wide. \$7.00 directory or free brochure. LOAN-A-HOME, 18N Darwood Place, Mt. Vernon, NY 10553, U.S.A. (2241)

#### **SYMPOSIUM**

### EMBO SYMPOSIUM 1975 DEVELOPMENTAL GENETICS

#### Hirschhorn-Heidelberg, April 30 - May 3 inclusive, 1975

Invited speakers will include:

M. Ashburner (U.K.), W. Beermann (Germany), A. Garcia Bellido (Spain), S. Benzer (U.S.A.), E. Bradbury (U.K.), S. Brenner (U.K.), A. Chovnick (U.S.A.), F. Crick (U.K.), E. Davidson (U.S.A.), W. Gehring (Switzerland), A. Gierer (Germany), F. Gros (France), F. Jacob (France), R. Kornberg (U.K.), P. Lawrence (U.K.), N. Ringertz (Sweden), K. Sander (Germany), P. Sengel (France), D. Suzuki (Canada), A. Tissières (Switzerland), L. Wolpert (U.K.), D. Yaffe (Israel).

Applications should reach J. Tooze, Executive Secretary, European Molecular Biology Organisation, 6900 Heidelberg, Postfach 1022.40, West Germany, before January 31, 1975. They should include a curriculum vitae, and an indication of the applicant's scientific background and current interests. Applicants will be informed whether or not they can be accepted during March 1975. A registration fee of 40 DM will be charged. Accommodation in Hirschhorn (15 DM to 30 DM per night) will be arranged by the Symposium Secretariat but participants will be responsible for their living and travel expenses. A small number of fellowships are available which will be awarded by the Organising Committee to young participants unable to obtain other sources of support. Persons wishing to compete for these few fellowships should so indicate in their letter of application.

The Organising Committee:

M. L. Birnstiel, S. Brenner, H. Bujard, A. Gierer, F. Gros, A. Monroy (Chairman), N. Ringertz, J. Tooze (Secretary) (2179)

### PHYSICS OF THE EARTH AND PLANETS

The main aim of this geophysics text is to give a connected account of the observations and arguments on which rests our understanding; of the physical nature of the Earth. Emphasis is placed on the physical principles behind instruments and obser knions and on the inferences that can be drawn from the data. Helpful appendixes contain mathematical developments, a selection of numerical data and some notes on early geophysicists.

MACMILLAN

### Molecular Biology comes of age

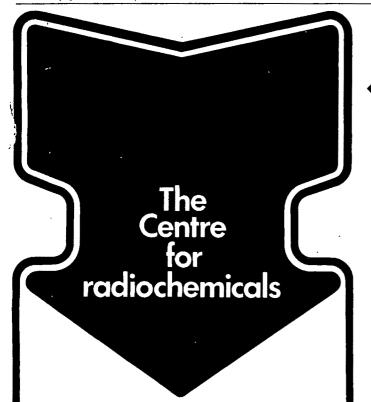

This special Nature Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, 'Molecular Biology Comes of Age' looks back on the circumstances surrounding the original appearance in Nature of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of 'Molecular Biology Comes of Age' are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and prorata). Please order copies by completing the order form below and returning it with the appropriate fee.

The most important prostaglandins

### are now available for your current research

They're ready: Prostaglandins  $E_1$  and  $E_2$ , and their methyl esters. Produced biosynthetically, they are better than 97% pure. And, best of all, you can get immediate delivery.

All this is the result of a major P-L Biochemicals commitment . . . to produce high purity lipid products for basic life science research. The emphasis now is on prostaglandins. PGE1 and PGE2 are the first products in this series. Coming soon. PGF2  $\alpha$  and prostaglandins from coral.

Let P-L supply your present—and future—prostaglandin requirements. For complete information, write or call today.

### Collected Nature

These specially designed Binders make attractive space-saving files for your Nature. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of Nature. Two volumes of Nature can be preserved in a single binder (three binders will hold the six volumes published annually), and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains. These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

# RARI MOLLIMES

By Miles Laboratories, Inc.

It's rare when you find one source for your research biochemical needs. But it's here, in these volumes ... the result of creativity, professionalism and growth in the field of biochemical research.

The result of our responsiveness to you in the areas of:

IMMOBILIZED BIOCHEMICALS
MOLECULAR BIOCHEMICALS
IMMUNOCHEMICALS
BLOOD PROTEINS
ENZYMES

Each features a complete listing of our available products, including sources, usage, prices and ordering information. Also available are abbreviated catalogs on LIPIDS, LECTINS and STABLE ISOTOPES. Once you receive our catalogs, you will continue to receive new product announcements and supplements.

Call or write the office nearest you and ask for your free collection of Rare Volumes.
